Now write out the ODD NUMBERS 1, 3,  $\dots$ ,  $2n-1$  in a row, and underneath write the even crossing number corresponding to each number. The Dowker NOTATION is this bottom row of numbers. When the sequence of even numbers can be broken into two permutations of consecutive sequences (such as  $\{4, 6, 2\}$   $\{10, 12, 8\}$ ), the knot is composite and is not uniquely determined by the Dowker notation. Otherwise, the knot is prime and the NOTATION uniquely defines a single knot (for amphichiral knots) or corresponds to a single knot or its MIRROR IMAGE (for chiral knots).

For general nonalternating knots, the procedure is modified slightly by making the sign of the even numbers

POSITIVE if the crossing is on the top strand, and NEGATIVE if it is on the bottom strand.

These data are available only for knots, but not for links, from Berkeley's gopher site.

### Dragon Curve

Nonintersecting curves which can be iterated to yield more and more sinuosity. They can be constructed by taking a path around a set of dots, representing a left turn by 1 and a right turn by 0. The first-order curve is then denoted 1. For higher order curves, add a 1 to the end, then copy the string of digits preceding it to the end but switching its center digit. For example, the second-order curve is generated as follows: (1)1  $\rightarrow$  (1)1(0)  $\rightarrow$  110, and the third as: (110)1  $\rightarrow$  (110)1(100)  $\rightarrow$  1101100. Continuing gives 110110011100100... (Sloane's A014577). The OCTAL representation sequence is 1, 6, 154, 66344, ... (Sloane's A003460). The dragon curves of orders 1 to 9 are illustrated below.

This procedure is equivalent to drawing a RIGHT ANGLE and subsequently replacing each RIGHT ANGLE with another smaller RIGHT ANGLE (Gardner 1978). In fact, the dragon curve can be written as a LINDENMAYER SYSTEM with initial string "FX", STRING REWRITING rules "X"  $\rightarrow$  "X+YF+", "Y"  $\rightarrow$  "-FX-Y", and angle  $90^\circ$ .

### Droz-Farny Circles

Draw a CIRCLE with center  $H$  which cuts the lines  $O_2O_3$ ,  $O_3O_1$ , and  $O_1O_2$  (where  $O_i$  are the MIDPOINTS) at  $P_1$ ,  $Q_1$ ;  $P_2$ ,  $Q_2$ ; and  $P_3$ ,  $Q_3$  respectively, then

$$\overline{A_1P_1} = \overline{A_2P_2} = \overline{A_3P_3} = \overline{A_1Q_1} = \overline{A_2Q_2} = \overline{A_3Q_3}.$$

Conversely, if equal CIRCLES are drawn about the VERTICES of a TRIANGLE, they cut the lines joining the MIDPOINTS of the corresponding sides in six points. These points lie on a CIRCLE whose center is the ORTHOCENTER. If  $r$  is the RADIUS of the equal CIRCLES centered on the vertices  $A_1$ ,  $A_2$ , and  $A_3$ , and  $R_0$  is the RADIUS of the CIRCLE about  $H$ , then

$$R_1^2 = 4R^2 + r^2 - \frac{1}{2}(a_1^2 + a_2^2 + a_3^2).$$

If the circles equal to the CIRCUMCIRCLE are drawn about the VERTICES of a triangle, they cut the lines joining midpoints of the adjacent sides in points of a CIRCLE  $R_2$  with center  $H$  and RADIUS

$$R_2^2 = 5R^2 - \frac{1}{2}(a_1^2 + a_2^2 + a_3^2).$$

It is equivalent to the circle obtained by drawing circles with centers at the feet of the altitudes and passing through the CIRCUMCENTER. These circles cut the corresponding sides in six points on a circle  $R'_2$  whose center is  $H$ .

Furthermore, the circles about the midpoints of the sides and passing through  $H$  cut the sides in six points lying on another equivalent circle  $R'_2$  whose center is  $O$ . In summary, the second Droz-Farny circle passes through 12 notable points, two on each of the sides and two on each of the lines joining midpoints of the sides.

#### Du Bois Raymond Constants

The constants  $C_n$  defined by

$$C_n \equiv \int_0^\infty \left| \frac{d}{dt} \left( \frac{\sin t}{t} \right)^n \right| dt - 1$$

which are difficult to compute numerically. The first few are

$$C_1 \approx 455$$

$$C_2 \approx 0.1945$$

$$C_3 \approx 0.028254$$

$$C_4 \approx 0.00524054.$$

Rather surprisingly, the second Du Bois Raymond constant is given analytically by

$$C_2 = \frac{1}{2}(e^2 - 7) = 0.1945280494 \dots$$

(Le Lionnais 1983).

### References

### Dual Basis

Given a CONTRAVARIANT BASIS  $\{\vec{e}_1, \dots, \vec{e}_n\}$ , its dual COVARIANT BASIS is given by

$$\vec{e}^\alpha \cdot \vec{e}_\beta = g(\vec{e}^\alpha, \vec{e}_\beta) = \delta_\beta^\alpha,$$

where  $g$  is the METRIC and  $\delta_\beta^\alpha$  is the mixed KRONECKER DELTA. In EUCLIDEAN SPACE with an ORTHONORMAL BASIS,

$$\vec{e}^j = \vec{e}_j,$$

so the BASIS and its dual are the same.

### Dual Bivector

A dual BIVECTOR is defined by

$$\tilde{X}_{ab} \equiv \frac{1}{2} \epsilon_{abcd} X^{cd},$$

and a self-dual BIVECTOR by

$$X_{ab}^* \equiv X_{ab} + i\tilde{X}_{ab}.$$

### Dual Graph

The dual graph  $G^*$  of a POLYHEDRAL GRAPH  $G$  has VERTICES each of which corresponds to a face of  $G$  and each of whose faces corresponds to a VERTEX of  $G$ . Two nodes in  $G^*$  are connected by an EDGE if the corresponding faces in  $G$  have a boundary EDGE in common.

### Dual Map

see PULLBACK MAP

### Dual Polyhedron

By the DUALITY PRINCIPLE, for every POLYHEDRON, there exists another POLYHEDRON in which faces and VERTICES occupy complementary locations. This POLYHEDRON is known as the dual, or RECIPROCAL. The dual polyhedron of a PLATONIC SOLID or ARCHIMEDEAN SOLID can be drawn by constructing EDGES tangent to the RECIPROCATING SPHERE (a.k.a. MIDSHERE and INTERSPHERE) which are PERPENDICULAR to the original EDGES.

The dual of a general solid can be computed by connecting the midpoints of the sides surrounding each VERTEX, and constructing the corresponding tangent POLYGON. (The tangent polygon is the polygon which is tangent to the CIRCUMCIRCLE of the POLYGON produced by connecting the MIDPOINT on the sides surrounding the given VERTEX.) The process is illustrated below for the PLATONIC SOLIDS. The POLYHEDRON COMPOUNDS

consisting of a POLYHEDRON and its dual are generally very attractive, and are also illustrated below for the PLATONIC SOLIDS.

The ARCHIMEDEAN SOLIDS and their duals are illustrated below.

The following table gives a list of the duals of the PLATONIC SOLIDS and KEPLER-POINSON SOLIDS together with the names of the POLYHEDRON-dual COMPOUNDS.

#### Dual Scalar

Given a third RANK TENSOR,

$$V_{ijk} \equiv \det \begin{bmatrix} \mathbf{A} & \mathbf{B} & \mathbf{C} \end{bmatrix},$$

where  $\det$  is the DETERMINANT, the dual scalar is defined as

$$V \equiv \frac{1}{3!} \epsilon_{ijk} V_{ijk},$$

where  $\epsilon_{ijk}$  is the LEVI-CIVITA TENSOR.

see also DUAL TENSOR, LEVI-CIVITA TENSOR

#### Dual Solid

see DUAL POLYHEDRON

#### Dual Tensor

Given an antisymmetric second RANK TENSOR  $C_{ij}$ , a dual pseudotensor  $C_i$  is defined by

$$C_i \equiv \frac{1}{2} \epsilon_{ijk} C_{jk}, \quad (1)$$

where

$$C_i \equiv \begin{bmatrix} C_{23} \\ C_{31} \\ C_{12} \end{bmatrix} \quad (2)$$

$$C_{jk} \equiv \begin{bmatrix} 0 & C_{12} & -C_{31} \\ -C_{12} & 0 & C_{23} \\ C_{31} & -C_{23} & 0 \end{bmatrix}. \quad (3)$$

#### Duality Principle

All the propositions in PROJECTIVE GEOMETRY occur in dual pairs which have the property that, starting from either proposition of a pair, the other can be immediately inferred by interchanging the parts played by the words "point" and "line." A similar duality exists for RECIPROCATION (Casey 1893).

#### Duality Theorem

Dual pairs of LINEAR PROGRAMS are in "strong duality" if both are possible. The theorem was first conceived by John von Neumann. The first written proof was an Air Force report by George Dantzig, but credit is usually given to Tucker, Kuhn, and Gale.

see also LINEAR PROGRAMMING

#### Duffing Differential Equation

The most general forced form of the Duffing equation is

$$\ddot{x} + \delta \dot{x} + (\beta x^3 \pm \omega_0^2 x) = A \sin(\omega t + \phi). \quad (1)$$

If there is no forcing, the right side vanishes, leaving

$$\ddot{x} + \delta \dot{x} + (\beta x^3 \pm \omega_0^2 x) = 0. \quad (2)$$

If  $\delta = 0$  and we take the plus sign,

$$\ddot{x} + \omega_0^2 x + \beta x^3 = 0. \quad (3)$$

This equation can display chaotic behavior. For  $\beta > 0$ , the equation represents a "hard spring," and for  $\beta < 0$ , it represents a "soft spring." If  $\beta < 0$ , the phase portrait curves are closed. Returning to (1), take  $\beta = 1$ ,  $\omega_0 = 1$ ,  $A = 0$ , and use the minus sign. Then the equation is

$$\ddot{x} + \delta \dot{x} + (x^3 - x) = 0 \quad (4)$$

(Ott 1993, p. 3). This can be written as a system of first-order ordinary differential equations by writing

$$\dot{x} = y, \quad (5)$$

$$\dot{y} = x - x^3 - \delta y. \quad (6)$$

The fixed points of these differential equations

$$\dot{x} = y = 0, \quad (7)$$

so  $y = 0$ , and

$$\dot{y} = x - x^3 - \delta y = x(1 - x^2) - 0 \quad (8)$$

giving  $x = 0, \pm 1$ . Differentiating,

$$\ddot{x} = \dot{y} = x - x^3 - \delta y \quad (9)$$

$$\ddot{y} = (1 - 3x^2)\dot{x} - \delta \dot{y} \quad (10)$$

$$\begin{bmatrix} \ddot{x} \\ \ddot{y} \end{bmatrix} = \begin{bmatrix} 0 & 1 \\ 1 - 3x^2 & -\delta \end{bmatrix} \begin{bmatrix} \dot{x} \\ \dot{y} \end{bmatrix}. \quad (11)$$

Examine the stability of the point  $(0,0)$ :

$$\begin{vmatrix} 0 - \lambda & 1 \\ 1 & -\delta - \lambda \end{vmatrix} = \lambda(\lambda + \delta) - 1 = \lambda^2 + \lambda\delta - 1 = 0 \quad (12)$$

$$\lambda_{\pm}^{(0,0)} = \frac{1}{2}(-\delta \pm \sqrt{\delta^2 + 4}). \quad (13)$$

But  $\delta^2 \geq 0$ , so  $\lambda_{\pm}^{(0,0)}$  is real. Since  $\sqrt{\delta^2 + 4} > |\delta|$ , there will always be one POSITIVE ROOT, so this fixed point is unstable. Now look at  $(\pm 1, 0)$ .

$$\begin{vmatrix} 0 - \lambda & 1 \\ -2 & -\delta - \lambda \end{vmatrix} = \lambda(\lambda + \delta) + 2 = \lambda^2 + \lambda\delta + 2 = 0 \quad (14)$$

$$\lambda_{\pm}^{(\pm 1,0)} = \frac{1}{2}(-\delta \pm \sqrt{\delta^2 - 8}). \quad (15)$$

For  $\delta > 0$ ,  $\Re[\lambda_{\pm}^{(\pm 1,0)}] < 0$ , so the point is asymptotically stable. If  $\delta = 0$ ,  $\lambda_{\pm}^{(\pm 1,0)} = \pm i\sqrt{2}$ , so the point is linearly stable. If  $\delta \in (-2\sqrt{2}, 0)$ , the radical gives an IMAGINARY PART and the REAL PART is  $> 0$ , so the point is unstable. If  $\delta = -2\sqrt{2}$ ,  $\lambda_{\pm}^{(\pm 1,0)} = \pm\sqrt{2}$ , which has a POSITIVE REAL ROOT, so the point is unstable. If  $\delta < -2\sqrt{2}$ , then  $|\delta| < \sqrt{\delta^2 - 8}$ , so both ROOTS are POSITIVE and the point is unstable. Summarizing,

$$\begin{cases} \text{asymptotically stable} & \delta > 0 \\ \text{linearly stable (superstable)} & \delta = 0 \\ \text{unstable} & \delta < 0. \end{cases} \quad (16)$$

Now specialize to the case  $\delta = 0$ , which can be integrated by quadratures. In this case, the equations become

$$\dot{x} = y \quad (17)$$

$$\dot{y} = x - x^3. \quad (18)$$

Differentiating (17) and plugging in (18) gives

$$\ddot{x} = \dot{y} = x - x^3. \quad (19)$$

Multiplying both sides by  $\dot{x}$  gives

$$\ddot{x}\dot{x} - \dot{x}x + \dot{x}x^3 = 0 \quad (20)$$

$$\frac{d}{dt}(\frac{1}{2}\dot{x}^2 - \frac{1}{2}x^2 + \frac{1}{4}x^4) = 0, \quad (21)$$

so we have an invariant of motion  $h$ ,

$$h \equiv \frac{1}{2}\dot{x}^2 - \frac{1}{2}x^2 + \frac{1}{4}x^4. \quad (22)$$

Solving for  $\dot{x}^2$  gives

$$\dot{x}^2 = \left(\frac{dx}{dt}\right)^2 = 2h + x^2 - \frac{1}{2}x^4 \quad (23)$$

$$\frac{dx}{dt} = \sqrt{2h + x^2 + \frac{1}{2}x^2}, \quad (24)$$

so

$$t = \int dt = \int \frac{dx}{\sqrt{2h + x^2 + \frac{1}{2}x^2}}. \quad (25)$$

Note that the invariant of motion  $h$  satisfies

$$\dot{x} = \frac{\partial h}{\partial \dot{x}} = \frac{\partial h}{\partial y} \quad (26)$$

$$\frac{\partial h}{\partial x} = -x + x^3 = -\dot{y}, \quad (27)$$

so the equations of the Duffing oscillator are given by the HAMILTONIAN SYSTEM

$$\begin{cases} \dot{x} = \frac{\partial h}{\partial y} \\ \dot{y} = -\frac{\partial h}{\partial x} \end{cases} \quad (28)$$

## Dupin's Cyclide

see CYCLIDE

## Dupin's Indicatrix

A pair of conics obtained by expanding an equation in MONGE'S FORM  $z = F(x, y)$  in a MACLAURIN SERIES

$$\begin{aligned} z &= z(0, 0) + z_1x + z_2y \\ &+ \frac{1}{2}(z_{11}x^2 + 2z_{12}xy + z_{22}y^2) + \dots \\ &= \frac{1}{2}(b_{11}x^2 + 2b_{12}xy + b_{22}y^2). \end{aligned}$$

This gives the equation

$$b_{11}x^2 + 2b_{12}xy + b_{22}y^2 = \pm 1.$$

Amazingly, the radius of the indicatrix in any direction is equal to the SQUARE ROOT of the RADIUS OF CURVATURE in that direction (Coxeter 1969).

## Dürer's Conchoid

These curves appear in Dürer's work *Instruction in Measurement with Compasses and Straight Edge* (1525) and arose in investigations of perspective. Dürer constructed the curve by drawing lines  $QRP$  and  $P'QR$  of length 16 units through  $Q(q, 0)$  and  $R(r, 0)$ , where  $q+r=13$ . The locus of  $P$  and  $P'$  is the curve, although Dürer found only one of the two branches of the curve.

The ENVELOPE of the lines  $QRP$  and  $P'QR$  is a PARABOLA, and the curve is therefore a GLISSETTE of a point on a line segment sliding between a PARABOLA and one of its TANGENTS.

Dürer called the curve "Muschellini," which means CONCHOID. However, it is not a true CONCHOID and so is sometimes called DÜRER'S SHELL CURVE. The Cartesian equation is

$$\begin{aligned} 2y^2(x^2 + y^2) - 2by^2(x + y) + (b^2 - 3a^2)y^2 - a^2x^2 \\ + 2a^2b(x + y) + a^2(a^2 - b^2) = 0. \end{aligned}$$

The above curves are for  $(a, b) = (3, 1), (3, 3), (3, 5)$ . There are a number of interesting special cases. If  $b = 0$ , the curve becomes two coincident straight lines  $x = 0$ . For  $a = 0$ , the curve becomes the line pair  $x = b/2$ ,  $x = -b/2$ , together with the CIRCLE  $x + y = b$ . If  $a = b/2$ , the curve has a CUSP at  $(-2a, a)$ .

### Dyadic

A linear POLYNOMIAL of DYADS  $\mathbf{AB} + \mathbf{CD} + \dots$  consisting of nine components  $A_{ij}$  which transform as

$$(A_{ij})' = \sum_{m,n} \frac{h_m h_n}{h'_i h'_j} \frac{\partial x_m}{\partial x'_i} \frac{\partial x_n}{\partial x'_j} A_{mn} \quad (1)$$

$$= \sum_{m,n} \frac{h'_i h'_j}{h_m h_n} \frac{\partial x'_i}{\partial x_m} \frac{\partial x'_j}{\partial x_n} A_{mn} \quad (2)$$

$$= \sum_{m,n} \frac{h'_i h_n}{h_m h'_j} \frac{\partial x'_i}{\partial x_m} \frac{\partial x_n}{\partial x'_j} A_{mn}. \quad (3)$$

Dyadics are often represented by Gothic capital letters. The use of dyadics is nearly archaic since TENSORS perform the same function but are notationally simpler.

A unit dyadic is also called the IDEMFACTOR and is defined such that

$$\mathbf{I} \cdot \mathbf{A} \equiv \mathbf{A}. \quad (4)$$

In CARTESIAN COORDINATES,

$$\mathbf{I} = \hat{\mathbf{x}}\hat{\mathbf{x}} + \hat{\mathbf{y}}\hat{\mathbf{y}} + \hat{\mathbf{z}}\hat{\mathbf{z}}, \quad (5)$$

and in SPHERICAL COORDINATES

$$\mathbf{I} = \nabla \mathbf{r}. \quad (6)$$

see also DYAD, TETRADIC

## Dynamical System

A means of describing how one state develops into another state over the course of time. Technically, a dynamical system is a smooth action of the reals or the INTEGERS on another object (usually a MANIFOLD). When the reals are acting, the system is called a continuous dynamical system, and when the INTEGERS are acting, the system is called a discrete dynamical system. If  $f$  is any CONTINUOUS FUNCTION, then the evolution of a variable  $x$  can be given by the formula

$$x_{n+1} = f(x_n). \quad (1)$$

This equation can also be viewed as a difference equation

$$x_{n+1} - x_n = f(x_n) - x_n, \quad (2)$$

so defining

$$g(x) \equiv f(x) - x \quad (3)$$

gives

$$x_{n+1} - x_n = g(x_n) * 1, \quad (4)$$

which can be read “as  $n$  changes by 1 unit,  $x$  changes by  $g(x)$ .” This is the discrete analog of the DIFFERENTIAL EQUATION

$$x'(n) = g(x(n)). \quad (5)$$

# E

e

The base of the NATURAL LOGARITHM, named in honor of Euler. It appears in many mathematical contexts involving LIMITS and DERIVATIVES, and can be defined by

$$e \equiv \lim_{x \rightarrow \infty} \left(1 + \frac{1}{x}\right)^x, \quad (1)$$

or by the infinite sum

$$e = \sum_{k=0}^{\infty} \frac{1}{k!}. \quad (2)$$

The numerical value of  $e$  is

$$e = 2.718281828459045235360287471352662497757 \dots \quad (3)$$

(Sloane's A001113).

Euler proved that  $e$  is IRRATIONAL, and Liouville proved in 1844 that  $e$  does not satisfy any QUADRATIC EQUATION with integral COEFFICIENTS. Hermite proved  $e$  to be TRANSCENDENTAL in 1873. It is not known if  $\pi + e$  or  $\pi/e$  is IRRATIONAL. However, it is known that  $\pi + e$  and  $\pi/e$  do not satisfy any POLYNOMIAL equation of degree  $\leq 8$  with INTEGER COEFFICIENTS of average size  $10^9$  (Bailey 1988, Borwein *et al.* 1989).

The special case of the EULER FORMULA

$$e^{ix} = \cos x + i \sin x \quad (4)$$

with  $x = \pi$  gives the beautiful identity

$$e^{i\pi} + 1 = 0, \quad (5)$$

an equation connecting the fundamental numbers  $i$ ,  $\pi$ ,  $e$ , 1, and 0 (ZERO).

Some CONTINUED FRACTION representations of  $e$  include

$$e = 2 + \frac{1}{1 + \frac{1}{2 + \frac{1}{3 + \frac{1}{\ddots}}}} \quad (6)$$

$$= [2, 1, 2, 1, 1, 4, 1, 1, 6, \dots] \quad (7)$$

(Sloane's A003417) and

$$\frac{e-1}{e+1} = [2, 6, 10, 14, \dots] \quad (8)$$

$$e-1 = [1, 1, 2, 1, 1, 4, 1, 1, 6, \dots] \quad (9)$$

$$\frac{1}{2}(e-1) = [0, 1, 6, 10, 14, \dots] \quad (10)$$

$$\sqrt{e} = [1, 1, 1, 1, 5, 1, 1, 1, 9, 1, \dots]. \quad (11)$$

The first few convergents of the CONTINUED FRACTION are 3, 8/3, 11/4, 19/7, 87/32, 106/39, 193/71, ... (Sloane's A007676 and A007677).

Using the RECURRENCE RELATION

$$a_n = n(a_{n-1} + 1) \quad (12)$$

with  $a_1 = a^{-1}$ , compute

$$\prod_{n=1}^{\infty} (1 + a_n^{-1}). \quad (13)$$

The result is  $e^a$ . Gosper gives the unusual equation connecting  $\pi$  and  $e$ ,

$$\begin{aligned} \sum_{n=1}^{\infty} \frac{1}{n^2} \cos\left(\frac{9}{n\pi + \sqrt{n^2\pi^2 - 9}}\right) \\ = -\frac{\pi^2}{12e^3} = -0.040948222 \dots \end{aligned} \quad (14)$$

Rabinowitz and Wagon (1995) give an ALGORITHM for computing digits of  $e$  based on earlier DIGITS, but a much simpler SPIGOT ALGORITHM was found by Sales (1968). Around 1966, MIT hacker Eric Jensen wrote a very concise program (requiring less than a page of assembly language) that computed  $e$  by converting from factorial base to decimal.

Let  $p(n)$  be the probability that a random ONE-TO-ONE function on the INTEGERS 1, ...,  $n$  has at least one FIXED POINT. Then

$$\lim_{n \rightarrow \infty} p(n) = \sum_{k=1}^{\infty} \frac{(-1)^{k+1}}{k!} = 1 - \frac{1}{e} = 0.6321205588 \dots \quad (15)$$

STIRLING'S FORMULA gives

$$\lim_{n \rightarrow \infty} \frac{(n!)^{1/n}}{n} = \frac{1}{e}. \quad (16)$$

Castellanos (1988) gives several curious approximations to  $e$ ,

$$e \approx 2 + \frac{54^2 + 41^2}{80^2} \quad (17)$$

$$\approx (\pi^4 + \pi^5)^{1/6} \quad (18)$$

$$\approx \frac{271801}{99990} \quad (19)$$

$$\approx \left(150 - \frac{87^3 + 12^5}{83^3}\right)^{1/5} \quad (20)$$

$$\approx 4 - \frac{300^4 - 100^4 - 1291^2 + 9^2}{91^5} \quad (21)$$

$$\approx \left(1097 - \frac{55^5 + 311^3 - 11^3}{68^5}\right)^{1/7}, \quad (22)$$

which are good to 6, 7, 9, 10, 12, and 15 digits respectively.

Examples of  $e$  MNEMONICS (Gardner 1959, 1991) include:

"By omnibus I traveled to Brooklyn" (6 digits).

"To disrupt a playroom is commonly a practice of children" (10 digits).

"It enables a numskull to memorize a quantity of numerals" (10 digits).

"I'm forming a mnemonic to remember a function in analysis" (10 digits).

"He repeats: I shouldn't be tipping, I shouldn't be toppling here!" (11 digits).

"In showing a painting to probably a critical or venomous lady, anger dominates. O take guard, or she raves and shouts" (21 digits). Here, the word "O" stands for the number 0.

A much more extensive mnemonic giving 40 digits is

"We present a mnemonic to memorize a constant so exciting that Euler exclaimed: '!' when first it was found, yes, loudly '!'. My students perhaps will compute  $e$ , use power or Taylor series, an easy summation formula, obvious, clear, elegant!"

(Barel 1995). In the latter, 0s are represented with "!"'. A list of  $e$  mnemonics in several languages is maintained by A. P. Hatzipolakis.

Scanning the decimal expansion of  $e$  until all  $n$ -digit numbers have occurred, the last appearing is 6, 12, 548, 1769, 92994, 513311, ... (Sloane's A032511). These end at positions 21, 372, 8092, 102128, 1061613, 12108841, ....

## $e$ -Divisor

$d$  is called an  $e$ -divisor (or EXPONENTIAL DIVISOR) if

$$n = p_1^{a_1} p_2^{a_2} \cdots p_r^{a_r}$$

if  $d|n$  and

$$d = p_1^{b_1} p_2^{b_2} \cdots p_r^{b_r}$$

where  $b_j|a_j$  with  $1 \leq j \leq r$ .

## $E_n$ -Function

The  $E_n(x)$  function is defined by the integral

$$E_n(x) \equiv \int_1^\infty \frac{e^{-xt} dt}{t^n} \quad (1)$$

and is given by the *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) function `ExpIntegralE[n,x]`. Defining  $t \equiv \eta^{-1}$  so that  $dt = -\eta^{-2} d\eta$ ,

$$E_n(x) = \int_0^1 e^{-x/\eta} \eta^{n-2} d\eta \quad (2)$$

$$E_n(0) = \frac{1}{n-1}. \quad (3)$$

The function satisfies the RECURRENCE RELATIONS

$$E'_n(x) = -E_{n-1}(x) \quad (4)$$

$$n E_{n+1}(x) = e^{-x} - x E_n(x). \quad (5)$$

Equation (4) can be derived from

$$E_n(x) = \int_1^\infty \frac{e^{-tx}}{t^n} dt \quad (6)$$

$$\begin{aligned} E'_n(x) &= \frac{d}{dx} \int_1^\infty \frac{e^{-tx}}{t^n} dt = \int_1^\infty \frac{d}{dx} \left( \frac{e^{-tx}}{t^n} \right) dt \\ &= - \int_1^\infty t \frac{e^{-tx}}{t^n} dt \\ &= - \int_1^\infty \frac{e^{-tx}}{t^{n-1}} dt = -E_{n-1}(x), \end{aligned} \quad (7)$$

and (5) using integrating by parts, letting

$$u = \frac{1}{t^n} \quad dv = e^{-tx} dt \quad (8)$$

$$du = -\frac{n}{t^{n+1}} dt \quad v = -\frac{e^{-tx}}{x}, \quad (9)$$

$$\begin{aligned} E_n(x) &= \int u dv = uv - \int v du \\ &= -\frac{e^{-tx}}{xt^n} - \frac{n}{x} \int_1^\infty \frac{e^{-tx}}{t^{n+1}} dx \\ &= x \int_1^\infty \frac{e^{-tx}}{t^n} dt \\ &= - \left[ \frac{1}{e^{tx} t^n} \right]_1^\infty - n \int_1^\infty \frac{e^{-tx}}{t^{n+1}} dx \\ &= x E_n(x) = e^{-x} - n E_{n+1}(x). \end{aligned} \quad (10)$$

Solving (10) for  $n E_n(x)$  gives (5). An asymptotic expansion gives

$$\begin{aligned} (n-1)! E_n(x) \\ = (-x)^{n-1} E_1(x) + e^{-x} \sum_{s=0}^n -2(n-s-2)!(-x)^s, \end{aligned} \quad (11)$$

so

$$E_n(x) = \frac{e^{-x}}{x} \left[ 1 - \frac{n}{x} + \frac{n(n+1)}{x^2} + \dots \right]. \quad (12)$$

The special case  $n = 1$  gives

$$E_1(x) \equiv -\text{ei}(-x) = \int_1^\infty \frac{e^{-tx}}{t} dt = \int_x^\infty \frac{e^{-u}}{u} du, \quad (13)$$

where  $\text{ei}(x)$  is the EXPONENTIAL INTEGRAL, which is also equal to

$$E_1(x) = -\gamma - \ln x - \sum_{n=1}^\infty \frac{(-1)^n x^n}{n!n}, \quad (14)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT.

$$E_1(0) = \infty \quad (15)$$

$$E_1(ix) = -\text{ci}(x) + i \text{si}(x), \quad (16)$$

where  $\text{ci}(x)$  and  $\text{si}(x)$  are the COSINE INTEGRAL and SINE INTEGRAL.

#### $E_t$ -Function

A function which arises in FRACTIONAL CALCULUS.

$$E_t(\nu, a) = \frac{1}{\Gamma(\nu)} e^{at} \int_0^t x^{\nu-1} e^{-ax} dx = t^\nu e^{at} \gamma(\nu, at), \quad (1)$$

where  $\gamma$  is the incomplete GAMMA FUNCTION and  $\Gamma$  the complete GAMMA FUNCTION. The  $E_t$  function satisfies the RECURRENCE RELATION

$$E_t(\nu, a) = a E_t(\nu + 1, a) + \frac{t^\nu}{\Gamma(\nu + 1)}. \quad (2)$$

A special value is

$$E_t(0, a) = e^{at}. \quad (3)$$

#### $e$ -Multiperfect Number

A number  $n$  is called a  $k$   $e$ -perfect number if  $\sigma_e(n) = kn$ , where  $\sigma_e(n)$  is the SUM of the  $e$ -DIVISORS of  $n$ .

see also  $e$ -DIVISOR,  $e$ -PERFECT NUMBER

#### References

- Guy, R. K. "Exponential-Perfect Numbers." §B17 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 73, 1994.

**e-Perfect Number**

A number  $n$  is called an  $e$ -perfect number if  $\sigma_e(n) = 2n$ , where  $\sigma_e(n)$  is the SUM of the  $e$ -DIVISORS of  $n$ . If  $m$  is SQUAREFREE, then  $\sigma_e(m) = m$ . As a result, if  $n$  is  $e$ -perfect and  $m$  is SQUAREFREE with  $m \perp n$ , then  $mn$  is  $e$ -perfect. There are no ODD  $e$ -perfect numbers.

see also  $e$ -DIVISOR

**Ear**

A PRINCIPAL VERTEX  $x_i$  of a SIMPLE POLYGON  $P$  is called an ear if the diagonal  $[x_{i-1}, x_{i+1}]$  that bridges  $x_i$  lies entirely in  $P$ . Two ears  $x_i$  and  $x_j$  are said to overlap if

$$\text{int}[x_{i-1}, x_i, x_{i+1}] \cap \text{int}[x_{j-1}, x_j, x_{j+1}] = \emptyset.$$

The TWO-EARS THEOREM states that, except for TRIANGLES, every SIMPLE POLYGON has at least two nonoverlapping ears.

**Eccentric**

Not CONCENTRIC.

see also CONCENTRIC, CONCYCLIC

**Eccentric Angle**

The angle  $\theta$  measured from the CENTER of an ELLIPSE to a point on the ELLIPSE.

see also ECCENTRICITY, ELLIPSE

**Eccentric Anomaly**

The ANGLE obtained by drawing the AUXILIARY CIRCLE of an ELLIPSE with center  $O$  and FOCUS  $F$ , and drawing a LINE PERPENDICULAR to the SEMIMAJOR AXIS and intersecting it at  $A$ . The ANGLE  $E$  is then defined as illustrated above. Then for an ELLIPSE with ECCENTRICITY  $e$ ,

$$AF = OF - AO = ae - a \cos E. \quad (1)$$

But the distance  $AF$  is also given in terms of the distance from the FOCUS  $r = FP$  and the SUPPLEMENT of the ANGLE from the SEMIMAJOR AXIS  $v$  by

$$AF = r \cos(\pi - v) = -r \cos v. \quad (2)$$

Equating these two expressions gives

$$r = \frac{a(\cos E - e)}{\cos v}, \quad (3)$$

which can be solved for  $\cos v$  to obtain

$$\cos v = \frac{a(\cos E - e)}{r}. \quad (4)$$

To get  $E$  in terms of  $r$ , plug (4) into the equation of the ELLIPSE

$$r = \frac{a(1 - e^2)}{1 + e \cos v} \quad (5)$$

$$r(1 + e \cos v) = a(1 - e^2) \quad (6)$$

$$r \left( 1 + \frac{ae \cos E}{r} - \frac{e^2}{r} \right) = r + ae \cos E - e^2 = a(1 - e^2) \quad (7)$$

$$r = a(1 - e^2) - ea \cos E + e^2 a = a(1 - e \cos E). \quad (8)$$

Differentiating gives

$$\dot{r} = ae\dot{E} \sin E. \quad (9)$$

The eccentric anomaly is a very useful concept in orbital mechanics, where it is related to the so-called mean anomaly  $M$  by KEPLER'S EQUATION

$$M = E - e \sin E. \quad (10)$$

$M$  can also be interpreted as the AREA of the shaded region in the above figure (Finch).

see also ECCENTRICITY, ELLIPSE, KEPLER'S EQUATION

#### Eccentricity

A quantity defined for a CONIC SECTION which can be given in terms of SEMIMAJOR and SEMIMINOR AXES for an ELLIPSE. For an ELLIPSE with SEMIMAJOR AXIS  $a$  and SEMIMINOR AXIS  $b$ ,

$$e \equiv \sqrt{1 - \frac{b^2}{a^2}}.$$

The eccentricity can be interpreted as the fraction of the distance to the semimajor axis at which the FOCUS lies,

$$e = \frac{c}{a},$$

where  $c$  is the distance from the center of the CONIC SECTION to the FOCUS. The table below gives the type of CONIC SECTION corresponding to various ranges of eccentricity  $e$ .

$e$	Curve
$e = 0$	circle
$0 < e < 1$	ellipse
$e = 1$	parabola
$e > 1$	hyperbola

#### Eckert IV Projection

The equations are

$$x = \frac{2}{\sqrt{\pi(4 + \pi)}} (\lambda - \lambda_0)(1 + \cos \theta) \quad (1)$$

$$y = 2 \sqrt{\frac{\pi}{4 + \pi}} \sin \theta, \quad (2)$$

where  $\theta$  is the solution to

$$\theta + \sin \theta \cos \theta + 2 \sin \theta = (2 + \frac{1}{2}\pi) \sin \phi. \quad (3)$$

This can be solved iteratively using NEWTON'S METHOD with  $\theta_0 = \phi/2$  to obtain

$$\Delta\theta = -\frac{\theta + \sin \theta \cos \theta + 2 \sin \theta - (2 - \frac{1}{2}\pi) \sin \phi}{2 \cos \theta (1 + \cos \theta)}. \quad (4)$$

The inverse FORMULAS are

$$\phi = \sin^{-1} \left( \frac{\theta + \sin \theta \cos \theta + 2 \sin \theta}{2 + \frac{1}{2}\pi} \right) \quad (5)$$

$$\lambda = \lambda_0 + \frac{\pi \sqrt{4 + \pi x}}{1 + \cos \theta}, \quad (6)$$

where

$$\theta = \sin^{-1} \left( \frac{y}{2} \sqrt{\frac{4 + \pi}{\pi}} \right). \quad (7)$$

**Ehrhart Polynomial**

Let  $\Delta$  denote an integral convex POLYTOPE of DIMENSION  $n$  in a lattice  $M$ , and let  $l_{\Delta}(k)$  denote the number of LATTICE POINTS in  $\Delta$  dilated by a factor of the integer  $k$ ,

$$l_{\Delta}(k) = \#(k\Delta \cap M) \quad (1)$$

for  $k \in \mathbb{Z}^+$ . Then  $l_{\Delta}$  is a polynomial function in  $k$  of degree  $n$  with rational coefficients

$$l_{\Delta}(k) = a_n k^n + a_{n-1} k^{n-1} + \dots + a_0 \quad (2)$$

called the Ehrhart polynomial (Ehrhart 1967, Pommer-sheim 1993). Specific coefficients have important geometric interpretations.

1.  $a_n$  is the CONTENT of  $\Delta$ .
2.  $a_{n-1}$  is half the sum of the CONTENTS of the  $(n-1)$ -D faces of  $\Delta$ .
3.  $a_0 = 1$ .

Let  $S_2(\Delta)$  denote the sum of the lattice lengths of the edges of  $\Delta$ , then the case  $n = 2$  corresponds to PICK'S THEOREM,

$$l_{\Delta}(k) = \text{Vol}(\Delta)k^2 + \frac{1}{2}S_2(\Delta)k + 1. \quad (3)$$

Let  $S_3(\Delta)$  denote the sum of the lattice volumes of the 2-D faces of  $\Delta$ , then the case  $n = 3$  gives

$$l_{\Delta}(k) = \text{Vol}(\Delta)k^3 + \frac{1}{2}S_3(\Delta)k^2 + a_1k + 1, \quad (4)$$

where a rather complicated expression is given by Pommerhsheim (1993), since  $a_1$  can unfortunately *not* be interpreted in terms of the edges of  $\Delta$ . The Ehrhart polynomial of the tetrahedron with vertices at  $(0, 0, 0)$ ,  $(a, 0, 0)$ ,  $(0, b, 0)$ ,  $(0, 0, c)$  is

$$l_{\Delta}(k) = \frac{1}{6}abck^3 + \frac{1}{4}(ab + ac + bc + d)k^2 + \left[ \frac{1}{12} \left( \frac{ac}{b} + \frac{bc}{a} + \frac{ab}{c} + \frac{d^2}{abc} \right) + \frac{1}{4}(a + b + c + A + B + C) - As \left( \frac{bc}{d}, \frac{aA}{d} \right) - Bs \left( \frac{ac}{d}, \frac{bB}{d} \right) - Cs \left( \frac{ab}{d}, \frac{cC}{d} \right) \right] k + 1, \quad (5)$$

where  $s(x, y)$  is a DEDEKIND SUM,  $A = \gcd(b, c)$ ,  $B = \gcd(a, c)$ ,  $C = \gcd(a, b)$  (here,  $\gcd$  is the GREATEST COMMON DENOMINATOR), and  $d = ABC$  (Pommerhsheim 1993).

### Ei

see EXPONENTIAL INTEGRAL,  $E_n$ -FUNCTION

### Eigenfunction

If  $\tilde{L}$  is a linear OPERATOR on a FUNCTION SPACE, then  $f$  is an eigenfunction for  $\tilde{L}$  and  $\lambda$  is the associated EIGENVALUE whenever  $\tilde{L}f = \lambda f$ .

see also EIGENVALUE, EIGENVECTOR

### Eigenvalue

Let  $A$  be a linear transformation represented by a MATRIX  $A$ . If there is a VECTOR  $\mathbf{X} \in \mathbb{R}^n \neq \mathbf{0}$  such that

$$\mathbf{AX} = \lambda \mathbf{X} \quad (1)$$

for some SCALAR  $\lambda$ , then  $\lambda$  is the eigenvalue of  $A$  with corresponding (right) EIGENVECTOR  $\mathbf{X}$ . Letting  $A$  be a  $k \times k$  MATRIX,

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \quad (2)$$

with eigenvalue  $\lambda$ , then the corresponding EIGENVECTORS satisfy

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \lambda \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix}, \quad (3)$$

which is equivalent to the homogeneous system

$$\begin{bmatrix} a_{11} - \lambda & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} - \lambda & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} - \lambda \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix}. \quad (4)$$

Equation (4) can be written compactly as

$$(\mathbf{A} - \lambda \mathbf{I})\mathbf{X} = \mathbf{0}, \quad (5)$$

where  $\mathbf{I}$  is the IDENTITY MATRIX.

As shown in CRAMER'S RULE, a system of linear equations has nontrivial solutions only if the DETERMINANT vanishes, so we obtain the CHARACTERISTIC EQUATION

$$|\mathbf{A} - \lambda \mathbf{I}| = 0. \quad (6)$$

If all  $k$   $\lambda$ s are different, then plugging these back in gives  $k - 1$  independent equations for the  $k$  components of each corresponding EIGENVECTOR. The EIGENVECTORS will then be orthogonal and the system is said to be nondegenerate. If the eigenvalues are  $n$ -fold DEGENERATE, then the system is said to be degenerate and the EIGENVECTORS are not linearly independent. In such cases, the additional constraint that the EIGENVECTORS be orthogonal,

$$\mathbf{X}_i \cdot \mathbf{X}_j = X_i X_j \delta_{ij}, \quad (7)$$

where  $\delta_{ij}$  is the KRONECKER DELTA, can be applied to yield  $n$  additional constraints, thus allowing solution for the EIGENVECTORS.

Assume  $A$  has nondegenerate eigenvalues  $\lambda_1, \lambda_2, \dots, \lambda_n$  and corresponding linearly independent EIGENVECTORS  $\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_k$  which can be denoted

$$\begin{bmatrix} x_{11} \\ x_{12} \\ \vdots \\ x_{1k} \end{bmatrix}, \begin{bmatrix} x_{21} \\ x_{22} \\ \vdots \\ x_{2k} \end{bmatrix}, \dots, \begin{bmatrix} x_{k1} \\ x_{k2} \\ \vdots \\ x_{kk} \end{bmatrix}. \quad (8)$$

Define the matrices composed of eigenvectors

$$\mathbf{P} \equiv [\mathbf{X}_1 \quad \mathbf{X}_2 \quad \cdots \quad \mathbf{X}_k] = \begin{bmatrix} x_{11} & x_{21} & \cdots & x_{k1} \\ x_{12} & x_{22} & \cdots & x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ x_{1k} & x_{2k} & \cdots & x_{kk} \end{bmatrix} \quad (9)$$

and eigenvalues

$$D \equiv \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k \end{bmatrix}, \quad (10)$$

where  $D$  is a DIAGONAL MATRIX. Then

$$\begin{aligned} AP &= A[X_1 \ X_2 \ \cdots \ X_k] \\ &= [AX_1 \ AX_2 \ \cdots \ AX_k] \\ &= [\lambda_1 X_1 \ \lambda_2 X_2 \ \cdots \ \lambda_k X_k] \\ &= \begin{bmatrix} \lambda_1 x_{11} & \lambda_2 x_{21} & \cdots & \lambda_k x_{k1} \\ \lambda_1 x_{12} & \lambda_2 x_{22} & \cdots & \lambda_k x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ \lambda_1 x_{1k} & \lambda_2 x_{2k} & \cdots & \lambda_k x_{kk} \end{bmatrix} \\ &= \begin{bmatrix} x_{11} & x_{21} & \cdots & x_{k1} \\ x_{12} & x_{22} & \cdots & x_{k2} \\ \vdots & \vdots & \ddots & \vdots \\ x_{1k} & x_{2k} & \cdots & x_{kk} \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 & \cdots & 0 \\ 0 & \lambda_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k \end{bmatrix} \\ &= PD, \end{aligned} \quad (11)$$

so

$$A = PDP^{-1}. \quad (12)$$

Furthermore,

$$\begin{aligned} A^2 &= (PDP^{-1})(PDP^{-1}) = PD(P^{-1}P)DP^{-1} \\ &= PD^2P^{-1}. \end{aligned} \quad (13)$$

By induction, it follows that for  $n > 0$ ,

$$A^n = PD^nP^{-1}. \quad (14)$$

The inverse of  $A$  is

$$A^{-1} = (PDP^{-1})^{-1} = PD^{-1}P^{-1}, \quad (15)$$

where the inverse of the DIAGONAL MATRIX  $D$  is trivially given by

$$D^{-1} = \frac{1}{k} \begin{bmatrix} \lambda_1^{-1} & 0 & \cdots & 0 \\ 0 & \lambda_2^{-1} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^{-1} \end{bmatrix}. \quad (16)$$

Equation (14) therefore holds for both POSITIVE and NEGATIVE  $n$ .

A further remarkable result involving the matrices  $P$  and  $D$  follows from the definition

$$\begin{aligned} e^A &\equiv \sum_{n=0}^{\infty} \frac{A^n}{n!} = \sum_{n=0}^{\infty} \frac{PD^nP^{-1}}{n!} \\ &= P \left( \sum_{n=0}^{\infty} \frac{D^n}{n!} \right) P^{-1} = Pe^DP^{-1}. \end{aligned} \quad (17)$$

Since  $D$  is a DIAGONAL MATRIX,

$$\begin{aligned} e^D &= \sum_{n=0}^{\infty} \frac{D^n}{n!} = \sum_{n=0}^{\infty} \frac{1}{n!} \begin{bmatrix} \lambda_1^n & 0 & \cdots & 0 \\ 0 & \lambda_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^n \end{bmatrix} \\ &= \begin{bmatrix} \sum_{i=0}^{\infty} \frac{\lambda_1^i}{i!} & 0 & \cdots & 0 \\ 0 & \sum_{i=0}^{\infty} \frac{\lambda_2^i}{i!} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sum_{i=0}^{\infty} \frac{\lambda_k^i}{i!} \end{bmatrix} \\ &= \begin{bmatrix} e^{\lambda_1} & 0 & \cdots & 0 \\ 0 & e^{\lambda_2} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & e^{\lambda_k} \end{bmatrix}, \end{aligned} \quad (18)$$

$e^D$  can be found using

$$D^n = \begin{bmatrix} \lambda_1^n & 0 & \cdots & 0 \\ 0 & \lambda_2^n & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \lambda_k^n \end{bmatrix}. \quad (19)$$

Assume we know the eigenvalue for

$$AX = \lambda X. \quad (20)$$

Adding a constant times the IDENTITY MATRIX to  $A$ ,

$$(A + cI)X = (\lambda + c)X \equiv \lambda'X, \quad (21)$$

so the new eigenvalues equal the old plus  $c$ . Multiplying  $A$  by a constant  $c$

$$(cA)X = c(\lambda X) \equiv \lambda'X, \quad (22)$$

so the new eigenvalues are the old multiplied by  $c$ .

Now consider a SIMILARITY TRANSFORMATION of  $A$ . Let  $|A|$  be the DETERMINANT of  $A$ , then

$$\begin{aligned} |Z^{-1}AZ - \lambda I| &= |Z^{-1}(A - \lambda I)Z| \\ &= |Z||A - \lambda I||Z^{-1}| = |A - \lambda I|, \end{aligned} \quad (23)$$

so the eigenvalues are the same as for  $A$ .

### Eigenvector

A right eigenvector satisfies

$$\mathbf{A}\mathbf{X} = \lambda\mathbf{X}, \quad (1)$$

where  $\mathbf{X}$  is a column VECTOR. The right EIGENVALUES therefore satisfy

$$|\mathbf{A} - \lambda\mathbf{I}| = 0. \quad (2)$$

A left eigenvector satisfies

$$\mathbf{X}\mathbf{A} = \lambda\mathbf{X}, \quad (3)$$

where  $\mathbf{X}$  is a row VECTOR, so

$$(\mathbf{X}\mathbf{A})^T = \lambda_L \mathbf{X}^T \quad (4)$$

$$\mathbf{A}^T \mathbf{X}^T = \lambda_L \mathbf{X}^T, \quad (5)$$

where  $\mathbf{X}^T$  is the transpose of  $\mathbf{X}$ . The left EIGENVALUES satisfy

$$|\mathbf{A}^T - \lambda_L \mathbf{I}| = |\mathbf{A}^T - \lambda_L \mathbf{I}^T| = |(\mathbf{A} - \lambda_L \mathbf{I})^T| = |(\mathbf{A} - \lambda_L \mathbf{I})|, \quad (6)$$

(since  $|\mathbf{A}| = |\mathbf{A}^T|$ ) where  $|\mathbf{A}|$  is the DETERMINANT of  $\mathbf{A}$ . But this is the same equation satisfied by the right EIGENVALUES, so the left and right EIGENVALUES are the same. Let  $\mathbf{X}_R$  be a MATRIX formed by the columns of the right eigenvectors and  $\mathbf{X}_L$  be a MATRIX formed by the rows of the left eigenvectors. Let

$$\mathbf{D} \equiv \begin{bmatrix} \lambda_1 & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & \lambda_n \end{bmatrix}. \quad (7)$$

Then

$$\mathbf{A}\mathbf{X}_R = \mathbf{X}_R\mathbf{D} \quad \mathbf{X}_L\mathbf{A} = \mathbf{D}\mathbf{X}_L \quad (8)$$

$$\mathbf{X}_L\mathbf{A}\mathbf{X}_R = \mathbf{X}_L\mathbf{X}_R\mathbf{D} \quad \mathbf{X}_L\mathbf{A}\mathbf{X}_R = \mathbf{D}\mathbf{X}_L\mathbf{X}_R, \quad (9)$$

so

$$\mathbf{X}_L\mathbf{X}_R\mathbf{D} = \mathbf{D}\mathbf{X}_L\mathbf{X}_R. \quad (10)$$

But this equation is of the form  $\mathbf{C}\mathbf{D} = \mathbf{D}\mathbf{C}$  where  $\mathbf{D}$  is a DIAGONAL MATRIX, so it must be true that  $\mathbf{C} \equiv \mathbf{X}_L\mathbf{X}_R$  is also diagonal. In particular, if  $\mathbf{A}$  is a SYMMETRIC MATRIX, then the left and right eigenvectors are transposes of each other. If  $\mathbf{A}$  is a SELF-ADJOINT MATRIX, then the left and right eigenvectors are conjugate HERMITIAN MATRICES.

Given a  $3 \times 3$  MATRIX  $\mathbf{A}$  with eigenvectors  $\mathbf{x}_1$ ,  $\mathbf{x}_2$ , and  $\mathbf{x}_3$  and corresponding EIGENVALUES  $\lambda_1$ ,  $\lambda_2$ , and  $\lambda_3$ , then an arbitrary VECTOR  $\mathbf{y}$  can be written

$$\mathbf{y} = b_1\mathbf{x}_1 + b_2\mathbf{x}_2 + b_3\mathbf{x}_3. \quad (11)$$

Applying the MATRIX  $\mathbf{A}$ ,

$$\begin{aligned} \mathbf{A}\mathbf{y} &= b_1\mathbf{A}\mathbf{x}_1 + b_2\mathbf{A}\mathbf{x}_2 + b_3\mathbf{A}\mathbf{x}_3 \\ &= \lambda_1 \left( b_1\mathbf{x}_1 + \frac{\lambda_2}{\lambda_1}b_2\mathbf{x}_2 + \frac{\lambda_3}{\lambda_1}b_3\mathbf{x}_3 \right), \end{aligned} \quad (12)$$

so

$$\mathbf{A}^n \mathbf{y} = \lambda_1^n \left[ b_1\mathbf{x}_1 + \left( \frac{\lambda_2}{\lambda_1} \right)^n b_2\mathbf{x}_2 + \left( \frac{\lambda_3}{\lambda_1} \right)^n b_3\mathbf{x}_3 \right]. \quad (13)$$

If  $\lambda_1 > \lambda_2, \lambda_3$ , it therefore follows that

$$\lim_{n \rightarrow \infty} \mathbf{A}^n \mathbf{y} = \lambda_1^n b_1 \mathbf{x}_1, \quad (14)$$

so repeated application of the matrix to an arbitrary vector results in a vector proportional to the EIGENVECTOR having the largest EIGENVALUE.

### Eight Curve

A curve also known as the GERONI LEMNISCATE. It is given by CARTESIAN COORDINATES

$$x^4 = a^2(x^2 - y^2), \quad (1)$$

POLAR COORDINATES,

$$r^2 = a^2 \sec^4 \theta \cos(2\theta), \quad (2)$$

and parametric equations

$$x = a \sin t \quad (3)$$

$$y = a \sin t \cos t. \quad (4)$$

The CURVATURE and TANGENTIAL ANGLE are

$$\kappa(t) = -\frac{3 \sin t + \sin(3t)}{2[\cos^2 t + \cos^2(2t)]^{3/2}} \quad (5)$$

$$\phi(t) = -\tan^{-1}[\cos t \sec(2t)]. \quad (6)$$

#### Eight-Point Circle Theorem

Let  $ABCD$  be a QUADRILATERAL with PERPENDICULAR DIAGONALS. The MIDPOINTS of the sides ( $a$ ,  $b$ ,  $c$ , and  $d$ ) determine a PARALLELOGRAM (the VARIGNON PARALLELOGRAM) with sides PARALLEL to the DIAGONALS. The eight-point circle passes through the four MIDPOINTS and the four feet of the PERPENDICULARS from the opposite sides  $a'$ ,  $b'$ ,  $c'$ , and  $d'$ .

#### Eikonal Equation

$$\sum_{i=1}^n \left( \frac{\partial u}{\partial x_i} \right)^2 = 1.$$

#### Eilenberg-Mac Lane Space

For any ABELIAN GROUP  $G$  and any NATURAL NUMBER  $n$ , there is a unique SPACE (up to HOMOTOPY type) such that all HOMOTOPY GROUPS except for the  $n$ th are trivial (including the 0th HOMOTOPY GROUPS, meaning the SPACE is path-connected), and the  $n$ th HOMOTOPY GROUP is ISOMORPHIC to the GROUP  $G$ . In the case where  $n = 1$ , the GROUP  $G$  can be non-ABELIAN as well.

Eilenberg-Mac Lane spaces have many important applications. One of them is that every TOPOLOGICAL SPACE has the HOMOTOPY type of an iterated FIBRATION of Eilenberg-Mac Lane spaces (called a POSTNIKOV SYSTEM). In addition, there is a spectral sequence relating the COHOMOLOGY of Eilenberg-Mac Lane spaces to the HOMOTOPY GROUPS of SPHERES.

#### Eilenberg-Mac Lane-Steenrod-Milnor Axioms

see EILENBERG-STEENROD AXIOMS

### Eilenberg-Steenrod Axioms

A family of FUNCTORS  $H_n(\cdot)$  from the CATEGORY of pairs of TOPOLOGICAL SPACES and continuous maps, to the CATEGORY of ABELIAN GROUPS and group homomorphisms satisfies the Eilenberg-Steenrod axioms if the following conditions hold.

1. LONG EXACT SEQUENCE OF A PAIR AXIOM. For every pair  $(X, A)$ , there is a natural long exact sequence

$$\begin{aligned} \dots \rightarrow H_n(A) \rightarrow H_n(X) \rightarrow H_n(X, A) \\ \rightarrow H_{n-1}(A) \rightarrow \dots, \end{aligned}$$

where the MAP  $H_n(A) \rightarrow H_n(X)$  is induced by the INCLUSION MAP  $A \rightarrow X$  and  $H_n(X) \rightarrow H_n(X, A)$  is induced by the INCLUSION MAP  $(X, \phi) \rightarrow (X, A)$ . The MAP  $H_n(X, A) \rightarrow H_{n-1}(A)$  is called the BOUNDARY MAP.

2. HOMOTOPY AXIOM. If  $f : (X, A) \rightarrow (Y, B)$  is homotopic to  $g : (X, A) \rightarrow (Y, B)$ , then their INDUCED MAPS  $f_* : H_n(X, A) \rightarrow H_n(Y, B)$  and  $g_* : H_n(X, A) \rightarrow H_n(Y, B)$  are the same.
3. EXCISION AXIOM. If  $X$  is a SPACE with SUBSPACES  $A$  and  $U$  such that the CLOSURE of  $A$  is contained in the interior of  $U$ , then the INCLUSION MAP  $(X \setminus U, A \setminus U) \rightarrow (X, A)$  induces an isomorphism  $H_n(X \setminus U, A \setminus U) \rightarrow H_n(X, A)$ .
4. DIMENSION AXIOM. Let  $X$  be a single point space.  $H_n(X) = 0$  unless  $n = 0$ , in which case  $H_0(X) = G$  where  $G$  are some GROUPS. The  $H_0$  are called the COEFFICIENTS of the HOMOLOGY theory  $H(\cdot)$ .

These are the axioms for a generalized homology theory. For a cohomology theory, instead of requiring that  $H(\cdot)$  be a FUNCTOR, it is required to be a co-functor (meaning the INDUCED MAP points in the opposite direction). With that modification, the axioms are essentially the same (except that all the induced maps point backwards).

see also ALEKSANDROV-ČECH COHOMOLOGY

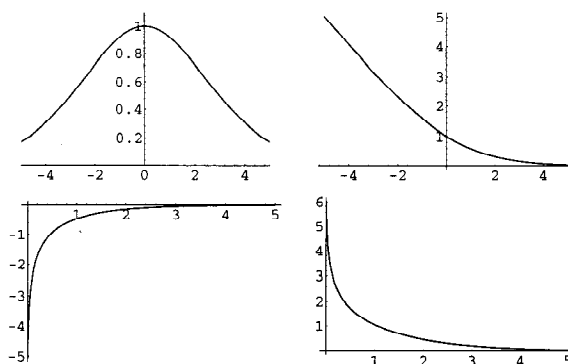

### Ein Function

$$\text{Ein}(z) \equiv \int_0^z \frac{(1 - e^{-t})}{t} dt = E_1(z) + \ln z + \gamma,$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $E_1$  is the  $E_n$ -FUNCTION with  $n = 1$ .

see also  $E_n$ -FUNCTION

### Einstein Functions

The functions  $x^2 e^x / (e^x - 1)^2$ ,  $x / (e^x - 1)$ ,  $\ln(1 - e^{-x})$ , and  $x / (e^x - 1) - \ln(1 - e^{-x})$ .

### References

Abramowitz, M. and Stegun, C. A. (Eds.). "Debye Functions." §27.1 in *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*, 9th printing. New York: Dover, pp. 999-1000, 1972.

### Einstein Summation

The implicit convention that repeated indices are summed over so that, for example,

$$a_i a_i \equiv \sum_i a_i a_i.$$

### Eisenstein Integer

The numbers  $a + b\omega$ , where

$$\omega \equiv \frac{1}{2}(-1 + i\sqrt{3})$$

is one of the ROOTS of  $z^3 = 1$ , the others being 1 and

$$\omega^2 = \frac{1}{2}(-1 - i\sqrt{3}).$$

Eisenstein integers are members of the QUADRATIC FIELD  $\mathbb{Q}(\sqrt{-3})$ , and the COMPLEX NUMBERS  $\mathbb{Z}[\omega]$ . Every Eisenstein integer has a unique factorization. Specifically, any NONZERO Eisenstein integer is uniquely the product of POWERS of  $-1$ ,  $\omega$ , and the "positive" EISENSTEIN PRIMES (Conway and Guy 1996). Every Eisenstein integer is within a distance  $|n|/\sqrt{3}$  of some multiple of a given Eisenstein integer  $n$ .

Dörrie (1965) uses the alternative notation

$$J \equiv \frac{1}{2}(1 + i\sqrt{3}) \quad (1)$$

$$O \equiv \frac{1}{2}(1 - i\sqrt{3}). \quad (2)$$

for  $-\omega^2$  and  $-\omega$ , and calls numbers of the form  $aJ + bO$  *G-NUMBERS*.  $O$  and  $J$  satisfy

$$J + O = 1 \quad (3)$$

$$JO = 1 \quad (4)$$

$$J^2 + O = 0 \quad (5)$$

$$O^2 + J = 0 \quad (6)$$

$$J^3 = -1 \quad (7)$$

$$O^3 = -1. \quad (8)$$

The sum, difference, and products of  $G$  numbers are also  $G$  numbers. The norm of a  $G$  number is

$$N(aJ + bO) = a^2 + b^2 - ab. \quad (9)$$

The analog of FERMAT'S THEOREM for Eisenstein integers is that a PRIME NUMBER  $p$  can be written in the form

$$a^2 - ab + b^2 = (a + b\omega)(a + b\omega^2)$$

IFF  $3 \nmid p + 1$ . These are precisely the PRIMES of the form  $3m^2 + n^2$  (Conway and Guy 1996).

### Eisenstein-Jacobi Integer

see EISENSTEIN INTEGER

### Eisenstein Prime

Let  $\omega$  be the CUBE ROOT of unity  $(-1 + i\sqrt{3})/2$ . Then the Eisenstein primes are

1. Ordinary PRIMES CONGRUENT to 2 (mod 3),
2.  $1 - \omega$  is prime in  $\mathbb{Z}[\omega]$ ,
3. Any ordinary PRIME CONGRUENT to 1 (mod 3) factors as  $\alpha\alpha^*$ , where each of  $\alpha$  and  $\alpha^*$  are primes in  $\mathbb{Z}[\omega]$  and  $\alpha$  and  $\alpha^*$  are not "associates" of each other (where associates are equivalent modulo multiplication by an EISENSTEIN UNIT).

### Eisenstein Series

$$E_r(t) = \sum'_{m,n} \frac{1}{(mt + n)^{2r}},$$

where the sum  $\Sigma'$  excludes  $m = n = 0$ ,  $\Im[t] > 0$ , and  $r$  is an INTEGER  $> 2$ . The Eisenstein series satisfies the remarkable property

$$E_r\left(\frac{at+b}{ct+d}\right) = (ct+d)^{2r} E_r(t).$$

see also RAMANUJAN-EISENSTEIN SERIES

### Eisenstein Unit

The Eisenstein units are the EISENSTEIN INTEGERS  $\pm 1$ ,  $\pm\omega$ ,  $\pm\omega^2$ , where

$$\omega = \frac{1}{2}(-1 + i\sqrt{3})$$

$$\omega^2 = \frac{1}{2}(-1 - i\sqrt{3}).$$

see also EISENSTEIN INTEGER, EISENSTEIN PRIME

#### References

- Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, pp. 220–223, 1996.

### Elastica

The elastica formed by bent rods and considered in physics can be generalized to curves in a RIEMANNIAN MANIFOLD which are a CRITICAL POINT for

$$F^\lambda(\gamma) = \int_\gamma (\kappa^2 + \lambda),$$

where  $\kappa$  is the GEODESIC CURVATURE of  $\gamma$ ,  $\lambda$  is a REAL NUMBER, and  $\gamma$  is closed or satisfies some specified

boundary condition. The curvature of an elastica must satisfy

$$0 = 2\kappa''(s) + \kappa^3(s) + 2\kappa(s)G(s) - \lambda\kappa(s),$$

where  $\kappa$  is the signed curvature of  $\gamma$ ,  $G(s)$  is the GAUSSIAN CURVATURE of the oriented Riemannian surface  $M$  along  $\gamma$ ,  $\kappa''$  is the second derivative of  $\kappa$  with respect to  $s$ , and  $\lambda$  is a constant.

#### Elation

A perspective COLLINEATION in which the center and axis are incident.

see also HOMOMOLOGY (GEOMETRY)

#### Elder's Theorem

A generalization of STANLEY'S THEOREM. It states that the total number of occurrences of an INTEGER  $k$  among all unordered PARTITIONS of  $n$  is equal to the number of occasions that a part occurs  $k$  or more times in a PARTITION, where a PARTITION which contains  $r$  parts that each occur  $k$  or more times contributes  $r$  to the sum in question.

see also STANLEY'S THEOREM

- Honsberger, R. *Mathematical Gems III*. Washington, DC: Math. Assoc. Amer, pp. 8–9, 1985.

#### Election

see EARLY ELECTION RESULTS, VOTING

#### Electric Motor Curve

see DEVIL'S CURVE

#### Element

If  $x$  is a member of a set  $A$ , then  $x$  is said to be an element of  $A$ , written  $x \in A$ . If  $x$  is not an element of  $A$ , this is written  $x \notin A$ . The term element also refers to a particular member of a GROUP, or entry in a MATRIX.

#### Elementary Function

A function built up of compositions of the EXPONENTIAL FUNCTION and the TRIGONOMETRIC FUNCTIONS and their inverses by ADDITION, MULTIPLICATION, DIVISION, root extractions (the ELEMENTARY OPERATIONS) under repeated compositions. Not all functions are elementary. For example, the NORMAL DISTRIBUTION FUNCTION

$$\Phi(x) \equiv \frac{1}{\sqrt{2\pi}} \int_0^x e^{-t^2/2} dt$$

is a notorious example of a nonelementary function. Nonelementary functions are called TRANSCENDENTAL FUNCTIONS.

see also ALGEBRAIC FUNCTION, ELEMENTARY OPERATION, ELEMENTARY SYMMETRIC FUNCTION, TRANSCENDENTAL FUNCTION

#### References

- Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, p. 145, 1993.

#### Elementary Matrix

The elementary MATRICES are the PERMUTATION MATRIX  $p_{ij}$  and the SHEAR MATRIX  $e_{ij}^s$ .

#### Elementary Operation

One of the operations of ADDITION, SUBTRACTION, MULTIPLICATION, DIVISION, and root extraction.

see also ALGEBRAIC FUNCTION, ELEMENTARY FUNCTION

#### Elementary Symmetric Function

The elementary symmetric functions  $\Pi_n$  on  $n$  variables  $\{x_1, \dots, x_n\}$  are defined by

$$\Pi_1 = \sum_{1 \leq i \leq n} x_i \quad (1)$$

$$\Pi_2 = \sum_{1 \leq i < j \leq n} x_i x_j \quad (2)$$

$$\Pi_3 = \sum_{1 \leq i < j < k \leq n} x_i x_j x_k \quad (3)$$

$$\Pi_4 = \sum_{1 \leq i < j < k < l \leq n} x_i x_j x_k x_l \quad (4)$$

$$\vdots$$

$$\Pi_n = \prod_{i \leq i \leq n} x_i. \quad (5)$$

Alternatively,  $\Pi_j$  can be defined as the coefficient of  $x^{n-j}$  in the GENERATING FUNCTION

$$\prod_{1 \leq i \leq n} (x + x_i). \quad (6)$$

The elementary symmetric functions satisfy the relationships

$$\sum_{i=1}^n x_i^2 = \Pi_1^2 - 2\Pi_2 \quad (7)$$

$$\sum_{i=1}^n x_i^3 = \Pi_1^3 - 3\Pi_1\Pi_2 + 3\Pi_3 \quad (8)$$

$$\sum_{i=1}^n x_i^4 = \Pi_1^4 - 4\Pi_1^2\Pi_2 + 2\Pi_2^2 + 4\Pi_1\Pi_3 - 4\Pi_4 \quad (9)$$

(Beeler *et al.* 1972, Item 6).

#### Elements

The classic treatise in geometry written by Euclid and used as a textbook for more than 1,000 years in western Europe. *The Elements*, which went through more than 2,000 editions and consisted of 465 propositions, are divided into 13 "books" (an archaic word for "chapters").

Book	Contents
1	triangles
2	rectangles
3	Circles
4	polygons
5	proportion
6	similarity
7-10	number theory
11	solid geometry
12	pyramids
13	platonic solids

The elements started with 23 definitions, five POSTULATES, and five "common notions," and systematically built the rest of plane and solid geometry upon this foundation. The five EUCLID'S POSTULATES are

1. It is possible to draw a straight LINE from any POINT to another POINT.
2. It is possible to produce a finite straight LINE continuously in a straight LINE.
3. It is possible to describe a CIRCLE with any CENTER and RADIUS.
4. All RIGHT ANGLES are equal to one another.
5. If a straight LINE falling on two straight LINES makes the interior ANGLES on the same side less than two RIGHT ANGLES, the straight LINES (if extended indefinitely) meet on the side on which the ANGLES which are less than two RIGHT ANGLES lie.

(Dunham 1990). Euclid's fifth postulate is known as the PARALLEL POSTULATE. After more than two millennia of study, this POSTULATE was found to be independent of the others. In fact, equally valid NON-EUCLIDEAN GEOMETRIES were found to be possible by changing the assumption of this POSTULATE. Unfortunately, Euclid's postulates were not rigorously complete and left a large number of gaps. Hilbert needed a total of 20 postulates to construct a logically complete geometry.

see also PARALLEL POSTULATE

#### Elevator Paradox

A fact noticed by physicist G. Gamow when he had an office on the second floor and physicist M. Stern had an office on the sixth floor of a seven-story building (Gamow and Stern 1958, Gardner 1986). Gamow noticed that about 5/6 of the time, the first elevator to stop on his floor was going down, whereas about the same fraction of time, the first elevator to stop on the sixth floor was going up. This actually makes perfect sense, since 5 of the 6 floors 1, 3, 4, 5, 6, 7 are above the second, and 5 of the 6 floors 1, 2, 3, 4, 5, 7 are below the sixth. However, the situation takes some unexpected turns if more than one elevator is involved, as discussed by Gardner (1986).

#### Elkies Point

Given POSITIVE numbers  $s_a$ ,  $s_b$ , and  $s_c$ , the Elkies point is the unique point  $Y$  in the interior of a TRIANGLE  $\triangle ABC$  such that the respective INRADIUS  $r_a$ ,  $r_b$ ,  $r_c$  of the TRIANGLES  $\triangle BYC$ ,  $\triangle CYA$ , and  $\triangle AYB$  satisfy  $r_a : r_b : r_c = s_a : s_b : s_c$ .

## Ellipse

A curve which is the LOCUS of all points in the PLANE the SUM of whose distances  $r_1$  and  $r_2$  from two fixed points  $F_1$  and  $F_2$  (the FOCI) separated by a distance of  $2c$  is a given POSITIVE constant  $2a$  (left figure). This results in the two-center BIPOLAR COORDINATE equation

$$r_1 + r_2 = 2a, \quad (1)$$

where  $a$  is the SEMIMAJOR AXIS and the ORIGIN of the coordinate system is at one of the FOCI. The ellipse can also be defined as the LOCUS of points whose distance from the FOCUS is proportional to the horizontal distance from a vertical line known as the DIRECTRIX (right figure).

The ellipse was first studied by Menaechmus, investigated by Euclid, and named by Apollonius. The FOCUS and DIRECTRIX of an ellipse were considered by Pappus. In 1602, Kepler believed that the orbit of Mars was OVAL; he later discovered that it was an ellipse with the Sun at one FOCUS. In fact, Kepler introduced the word "FOCUS" and published his discovery in 1609. In 1705 Halley showed that the comet which is now named after him moved in an elliptical orbit around the Sun (MacTutor Archive).

A ray passing through a FOCUS will pass through the other focus after a single bounce. Reflections not passing through a FOCUS will be tangent to a confocal HYPERBOLA or ELLIPSE, depending on whether the ray passes between the FOCI or not. Let an ellipse lie along the  $x$ -AXIS and find the equation of the figure (1) where  $r_1$  and  $r_2$  are at  $(-c, 0)$  and  $(c, 0)$ . In CARTESIAN COORDINATES,

$$\sqrt{(x+c)^2 + y^2} + \sqrt{(x-c)^2 + y^2} = 2a. \quad (2)$$

Bring the second term to the right side and square both sides,

$$(x+c)^2 + y^2 = 4a^2 - 4a\sqrt{(x-c)^2 + y^2} + (x-c)^2 + y^2. \quad (3)$$

Now solve for the SQUARE ROOT term and simplify

$$\begin{aligned} & \sqrt{(x-c)^2 + y^2} \\ &= -\frac{1}{4a}(x^2 + 2xc + c^2 + y^2 - 4a^2 - x^2 + 2xc - c^2 - y^2) \\ &= -\frac{1}{4a}(4xc - 4a^2) = a - \frac{c}{a}x. \quad (4) \end{aligned}$$

Square one final time to clear the remaining SQUARE ROOT,

$$x^2 - 2xc + c^2 + y^2 = a^2 - 2cx + \frac{c^2}{a^2}x^2. \quad (5)$$

Grouping the  $x$  terms then gives

$$x^2 \frac{a^2 - c^2}{a^2} + y^2 = a^2 - c^2, \quad (6)$$

which can be written in the simple form

$$\frac{x^2}{a^2} + \frac{y^2}{a^2 - c^2} = 1. \quad (7)$$

Defining a new constant

$$b^2 \equiv a^2 - c^2 \quad (8)$$

puts the equation in the particularly simple form

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1. \quad (9)$$

The parameter  $b$  is called the SEMIMINOR AXIS by analogy with the parameter  $a$ , which is called the SEMIMAJOR AXIS. The fact that  $b$  as defined above is actually the SEMIMINOR AXIS is easily shown by letting  $r_1$  and  $r_2$  be equal. Then two RIGHT TRIANGLES are produced, each with HYPOTENUSE  $a$ , base  $c$ , and height  $b \equiv \sqrt{a^2 - c^2}$ . Since the largest distance along the MINOR AXIS will be achieved at this point,  $b$  is indeed the SEMIMINOR AXIS.

If, instead of being centered at  $(0, 0)$ , the CENTER of the ellipse is at  $(x_0, y_0)$ , equation (9) becomes

$$\frac{(x-x_0)^2}{a^2} + \frac{(y-y_0)^2}{b^2} = 1. \quad (10)$$

As can be seen from the CARTESIAN EQUATION for the ellipse, the curve can also be given by a simple parametric form analogous to that of a CIRCLE, but with the  $x$  and  $y$  coordinates having different scalings,

$$x = a \cos t \quad (11)$$

$$y = b \sin t. \quad (12)$$

The unit TANGENT VECTOR of the ellipse so parameterized is

$$x_T(t) = -\frac{a \sin t}{\sqrt{b^2 \cos^2 t + a^2 \sin^2 t}} \quad (13)$$

$$y_T(t) = \frac{b \cos t}{\sqrt{b^2 \cos^2 t + a^2 \sin^2 t}}. \quad (14)$$

A sequence of NORMAL and TANGENT VECTORS are plotted below for the ellipse.

For an ellipse centered at the ORIGIN but inclined at an arbitrary ANGLE  $\theta$  to the  $x$ -AXIS, the parametric equations are

$$\begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix} \begin{bmatrix} a \cos t \\ b \sin t \end{bmatrix} = \begin{bmatrix} a \cos \theta \cos t + b \sin \theta \sin t \\ -a \sin \theta \cos t + b \cos \theta \sin t \end{bmatrix}. \quad (15)$$

In POLAR COORDINATES, the ANGLE  $\theta'$  measured from the *center* of the ellipse is called the ECCENTRIC ANGLE. Writing  $r'$  for the distance of a point from the ellipse center, the equation in POLAR COORDINATES is just given by the usual

$$x = r' \cos \theta' \quad (16)$$

$$y = r' \sin \theta'. \quad (17)$$

Here, the coordinates  $\theta'$  and  $r'$  are written with primes to distinguish them from the more common polar coordinates for an ellipse which are centered on a *focus*. Plugging the polar equations into the Cartesian equation (9) and solving for  $r'^2$  gives

$$r'^2 = \frac{b^2 a^2}{b^2 \cos^2 \theta' + a^2 \sin^2 \theta'}. \quad (18)$$

Define a new constant  $0 \leq e < 1$  called the ECCENTRICITY (where  $e = 0$  is the case of a CIRCLE) to replace  $b$

$$e \equiv \sqrt{1 - \frac{b^2}{a^2}}, \quad (19)$$

from which it also follows from (8) that

$$a^2 e^2 = a^2 - b^2 \equiv c^2 \quad (20)$$

$$c = ae \quad (21)$$

$$b^2 = a^2(1 - e^2). \quad (22)$$

Therefore (18) can be written as

$$r'^2 = \frac{a^2(1 - e^2)}{1 - e^2 \cos^2 \theta'} \quad (23)$$

$$r' = a \sqrt{\frac{1 - e^2}{1 - e^2 \cos^2 \theta'}}. \quad (24)$$

If  $e \ll 1$ , then

$$r' = a \left\{ 1 - \frac{1}{2} e^2 \sin^2 \theta' - \frac{1}{16} e^4 [5 + 3 \cos(2\theta')] \sin^2 \theta' + \dots \right\}, \quad (25)$$

so

$$\frac{\Delta r'}{a} \equiv \frac{a - r'}{a} \approx \frac{1}{2} e^2 \sin^2 \theta'. \quad (26)$$

If  $r$  and  $\theta$  are measured from a FOCUS instead of from the center, as they commonly are in orbital mechanics, then the equations of the ellipse are

$$x = c + r \cos \theta \quad (27)$$

$$y = r \sin \theta, \quad (28)$$

and (9) becomes

$$\frac{(c + r \cos \theta)^2}{a^2} + \frac{r^2 \sin^2 \theta}{b^2} = 1. \quad (29)$$

Clearing the DENOMINATORS gives

$$b^2(c^2 + 2cr \cos \theta + r^2 \cos^2 \theta) + a^2 r^2 \sin^2 \theta = a^2 b^2 \quad (30)$$

$$b^2 c^2 + 2rcb^2 \cos \theta + b^2 r^2 \cos^2 \theta + a^2 r^2 - a^2 r^2 \cos^2 \theta = a^2 b^2. \quad (31)$$

Plugging in (21) and (22) to re-express  $b$  and  $c$  in terms of  $a$  and  $e$ ,

$$a^2(1 - e^2)a^2 e^2 + 2aea^2(1 - e^2)r \cos \theta + a^2(1 - e^2)r^2 \cos^2 \theta + a^2 r^2 - a^2 r^2 \cos^2 \theta = a^2[a^2(1 - e^2)]. \quad (32)$$

Simplifying,

$$-r^2 + [er \cos \theta - a(1 - e^2)]^2 = 0 \quad (33)$$

$$r = \pm[er \cos \theta - a(1 - e^2)]. \quad (34)$$

The sign can be determined by requiring that  $r$  must be POSITIVE. When  $e = 0$ , (34) becomes  $r = \pm(-a)$ , but

since  $a$  is always POSITIVE, we must take the NEGATIVE sign, so (34) becomes

$$r = a(1 - e^2) - er \cos \theta \quad (35)$$

$$r(1 + e \cos \theta) = a(1 - e^2) \quad (36)$$

$$r = \frac{a(1 - e^2)}{1 + e \cos \theta}. \quad (37)$$

The distance from a FOCUS to a point with horizontal coordinate  $x$  is found from

$$\cos \theta = \frac{c + x}{r}. \quad (38)$$

Plugging this into (37) yields

$$r + e(c + x) = a(1 - e^2) \quad (39)$$

$$r = a(1 - e^2) - e(c + x). \quad (40)$$

Summarizing relationships among the parameters characterizing an ellipse,

$$b = a\sqrt{1 - e^2} = \sqrt{a^2 - c^2} \quad (41)$$

$$c = \sqrt{a^2 - b^2} = ae \quad (42)$$

$$e = \sqrt{1 - \frac{b^2}{a^2}} = \frac{c}{a}. \quad (43)$$

The ECCENTRICITY can therefore be interpreted as the position of the FOCUS as a fraction of the SEMIMAJOR AXIS.

In PEDAL COORDINATES with the PEDAL POINT at the FOCUS, the equation of the ellipse is

$$\frac{b^2}{p^2} = \frac{2a}{r} - 1. \quad (44)$$

To find the RADIUS OF CURVATURE, return to the parametric coordinates centered at the center of the ellipse and compute the first and second derivatives,

$$x' = -a \sin t \quad (45)$$

$$y' = b \cos t \quad (46)$$

$$x'' = -a \cos t \quad (47)$$

$$y'' = -b \sin t. \quad (48)$$

Therefore,

$$\begin{aligned} R &= \frac{(x'^2 + y'^2)^{3/2}}{x'y'' - x''y'} \\ &= \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{3/2}}{-a \sin t(-b \sin t) - (a \cos t)(b \cos t)} \\ &= \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{3/2}}{ab(\sin^2 t + \cos^2 t)} \\ &= \frac{(a^2 \sin^2 t + b^2 \cos^2 t)^{3/2}}{ab}. \end{aligned} \quad (49)$$

Similarly, the unit TANGENT VECTOR is given by

$$\hat{\mathbf{T}} = \begin{bmatrix} -a \sin t \\ b \cos t \end{bmatrix} \frac{1}{\sqrt{a^2 \sin^2 t + b^2 \cos^2 t}}. \quad (50)$$

The ARC LENGTH of the ellipse can be computed using

$$\begin{aligned} s &= \int \sqrt{x'^2 + y'^2} dt = \int \sqrt{a^2 \cos^2 t + b^2 \sin^2 t} dt \\ &= a \int \sqrt{(1 - \sin^2 t) + \frac{b^2}{a^2} \sin^2 t} dt \\ &= a \int \sqrt{1 - \left(1 - \frac{b^2}{a^2}\right) \sin^2 t} dt \\ &= a \int \sqrt{1 - e^2 \sin^2 t} dt = aE(t, e), \end{aligned} \quad (51)$$

where  $E$  is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND. Again, note that  $t$  is a parameter which does not have a direct interpretation in terms of an ANGLE. However, the relationship between the polar angle from the ellipse center  $\theta$  and the parameter  $t$  follows from

$$\theta = \tan^{-1} \left( \frac{y}{x} \right) = \tan^{-1} \left( \frac{b}{a} \tan t \right). \quad (52)$$

This function is illustrated above with  $\theta$  shown as the solid curve and  $t$  as the dashed, with  $b/a = 0.6$ . Care must be taken to make sure that the correct branch of the INVERSE TANGENT function is used. As can be seen,  $\theta$  weaves back and forth around  $t$ , with crossings occurring at multiples of  $\pi/2$ .

The CURVATURE and TANGENTIAL ANGLE of the ellipse are given by

$$\kappa = \frac{ab}{(b^2 \cos^2 t + a^2 \sin^2 t)^{3/2}} \quad (53)$$

$$\phi = -\tan^{-1} \left( \frac{b}{a} \cos t \right). \quad (54)$$

The entire PERIMETER  $p$  of the ellipse is given by setting  $t = 2\pi$  (corresponding to  $\theta = 2\pi$ ), which is equivalent to four times the length of one of the ellipse's QUADRANTS,

$$p = aE(2\pi, e) = 4aE(\tfrac{1}{2}\pi, e) = 4aE(e), \quad (55)$$

where  $E(e)$  is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND with MODULUS  $k$ . The PERIMETER can be computed numerically by the rapidly converging GAUSS-KUMMER SERIES

$$\begin{aligned} p &= \pi(a+b) \sum_{n=0}^{\infty} \left(\frac{1}{2}\right)^n h^{2n} \\ &= \pi(a+b) \left(1 + \frac{1}{4}h^2 + \frac{1}{64}h^4 + \frac{1}{256}h^6 + \dots\right), \end{aligned} \quad (56)$$

where

$$h \equiv \frac{a-b}{a+b} \quad (57)$$

and  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. Approximations to the PERIMETER include

$$p \approx \pi\sqrt{2(a^2 + b^2)} \quad (58)$$

$$\approx \pi[3(a+b) - \sqrt{(a+3b)(3a+b)}] \quad (59)$$

$$\approx \pi(a+b) \left(1 + \frac{3t}{10 + \sqrt{4-3t}}\right), \quad (60)$$

where the last two are due to Ramanujan (1913-14),

$$t \equiv \left(\frac{a-b}{a+b}\right)^2, \quad (61)$$

and (60) is accurate to within  $\sim 3 \cdot 2^{-17}t^5$ .

The maximum and minimum distances from the FOCUS are called the APOAPSIS and PERIAPSIS, and are given by

$$r_+ = r_{\text{apoapsis}} = a(1+e) \quad (62)$$

$$r_- = r_{\text{periapsis}} = a(1-e). \quad (63)$$

The AREA of an ellipse may be found by direct INTEGRATION

$$\begin{aligned} A &= \int_{-a}^a \int_{-b\sqrt{a^2-x^2}/a}^{b\sqrt{a^2-x^2}/a} dy dx = \int_{-a}^a \frac{2b}{a} \sqrt{a^2-x^2} dx \\ &= \frac{2b}{a} \left\{ \frac{1}{2} \left[ x\sqrt{a^2-x^2} + a^2 \sin^{-1} \left( \frac{x}{a} \right) \right] \right\}_{x=-a}^a \\ &= ab[\sin^{-1} 1 - \sin^{-1}(-1)] = ab \left[ \frac{\pi}{2} - \left( -\frac{\pi}{2} \right) \right] = \pi ab. \end{aligned} \quad (64)$$

The AREA can also be computed more simply by making the change of coordinates  $x' \equiv (b/a)x$  and  $y' \equiv y$  from

the elliptical region  $R$  to the new region  $R'$ . Then the equation becomes

$$\frac{1}{a^2} \left( \frac{a}{b} x' \right)^2 + \frac{y'^2}{b^2} = 1, \quad (65)$$

or  $x'^2 + y'^2 = b^2$ , so  $R'$  is a CIRCLE of RADIUS  $b$ . Since

$$\frac{\partial x}{\partial x'} = \left( \frac{\partial x'}{\partial x} \right)^{-1} = \left( \frac{b}{a} \right)^{-1} = \frac{a}{b}, \quad (66)$$

the JACOBIAN is

$$\left| \frac{\partial(x,y)}{\partial(x',y')} \right| = \begin{vmatrix} \frac{\partial x}{\partial x'} & \frac{\partial y}{\partial x'} \\ \frac{\partial x}{\partial y'} & \frac{\partial y}{\partial y'} \end{vmatrix} = \begin{vmatrix} \frac{a}{b} & 0 \\ 0 & 1 \end{vmatrix} = \frac{a}{b}. \quad (67)$$

The AREA is therefore

$$\begin{aligned} \iint_R dx dy &= \iint_{R'} \left| \frac{\partial(x,y)}{\partial(x',y')} \right| dx' dy' \\ &= \frac{a}{b} \iint_{R'} dx' dy' = \frac{a}{b} (\pi b^2) = \pi ab, \end{aligned} \quad (68)$$

as before. The AREA of an arbitrary ellipse given by the QUADRATIC EQUATION

$$ax^2 + bxy + cy^2 = 1 \quad (69)$$

is

$$A = \frac{2\pi}{\sqrt{4ac - b^2}}. \quad (70)$$

The AREA of an ELLIPSE with semiaxes  $a$  and  $b$  with respect to a PEDAL POINT  $P$  is

$$A = \frac{1}{2}\pi(a^2 + b^2 + |OP|^2). \quad (71)$$

The ellipse INSCRIBED in a given TRIANGLE and tangent at its MIDPOINTS is called the MIDPOINT ELLIPSE. The LOCUS of the centers of the ellipses INSCRIBED in a TRIANGLE is the interior of the MEDIAL TRIANGLE. Newton gave the solution to inscribing an ellipse in a convex QUADRILATERAL (Dörrie 1965, p. 217). The centers of the ellipses INSCRIBED in a QUADRILATERAL all lie on the straight line segment joining the MIDPOINTS of the DIAGONALS (Chakerian 1979, pp. 136-139).

The AREA of an ellipse with BARYCENTRIC COORDINATES  $(\alpha, \beta, \gamma)$  INSCRIBED in a TRIANGLE of unit AREA is

$$\Delta = \pi \sqrt{(1-2\alpha)(1-2\beta)(1-2\gamma)}. \quad (72)$$

(Chakerian 1979, pp. 142-145).

The LOCUS of the apex of a variable CONE containing an ellipse fixed in 3-space is a HYPERBOLA through the FOCI of the ellipse. In addition, the LOCUS of the apex of a CONE containing that HYPERBOLA is the original ellipse. Furthermore, the ECCENTRICITIES of the ellipse and HYPERBOLA are reciprocals. The LOCUS of centers

of a PAPPUS CHAIN of CIRCLES is an ellipse. Surprisingly, the locus of the end of a garage door mounted on rollers along a vertical track but extending beyond the track is a quadrant of an ellipse (the envelopes of positions is an ASTROID).

#### Ellipse Caustic Curve

For an ELLIPSE given by

$$x = r \cos t \quad (1)$$

$$y = \sin t \quad (2)$$

with light source at  $(x, 0)$ , the CAUSTIC is

$$x = \frac{N_x}{D_x} \quad (3)$$

$$y = \frac{N_y}{D_y}, \quad (4)$$

where

$$\begin{aligned} N_x = & 2rx(3 - 5r^2) + (-6r^2 + 6r^4 - 3x^2 + 9r^2x^2) \cos t \\ & + 6rx(1 - r^2) \cos(2t) \\ & + (-2r^2 + 2r^4 - x^2 - r^2x^2) \cos(3t) \end{aligned} \quad (5)$$

$$\begin{aligned} D_x = & 2r(1 + 2r^2 + 4x^2) + 3x(1 - 5r^2) \cos t \\ & + (6r + 6r^3) \cos(2t) + x(1 - r^2) \cos(3t) \end{aligned} \quad (6)$$

$$N_y = 8r(-1 + r^2 - x^2) \sin^3 t \quad (7)$$

$$\begin{aligned} D_y = & 2r(-1 - r^2 - 4x^2) + 3(-x + 5r^2) \cos t \\ & + 6r(1 - r^2) \cos(2t) + x(-1 + r^2) \cos(3t). \end{aligned} \quad (8)$$

At  $(\infty, 0)$ ,

$$x = \frac{\cos t[-1 + 5r^2 - \cos(2t)(1 + r^2)]}{4r} \quad (9)$$

$$y = \sin^3 t. \quad (10)$$

Ellipse Envelope

Consider the family of ELLIPSES

$$\frac{x^2}{c^2} + \frac{y^2}{(1-c)^2} - 1 = 0 \quad (1)$$

for  $c \in [0, 1]$ . The PARTIAL DERIVATIVE with respect to  $c$  is

$$-\frac{2x^2}{c^3} + \frac{2y^2}{(1-c)^3} = 0 \quad (2)$$

$$\frac{x^2}{c^3} - \frac{y^2}{(1-c)^3} = 0. \quad (3)$$

Combining (1) and (3) gives the set of equations

$$\begin{bmatrix} \frac{1}{c^2} & \frac{1}{(1-c)^2} \\ \frac{1}{c^3} & -\frac{1}{(1-c)^3} \end{bmatrix} \begin{bmatrix} x^2 \\ y^2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \quad (4)$$

$$\begin{aligned} \begin{bmatrix} x^2 \\ y^2 \end{bmatrix} &= \frac{1}{\Delta} \begin{bmatrix} -\frac{1}{(1-c)^3} & -\frac{1}{(1-c)^2} \\ -\frac{1}{c^3} & \frac{1}{c^2} \end{bmatrix} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\ &= \frac{1}{\Delta} \begin{bmatrix} -\frac{1}{(1-c)^3} \\ -\frac{1}{c^3} \end{bmatrix}, \end{aligned} \quad (5)$$

where the DISCRIMINANT is

$$\Delta = -\frac{1}{c^2(1-c)^3} - \frac{1}{c^3(1-c)^2} = -\frac{1}{c^3(1-c)^3}, \quad (6)$$

so (5) becomes

$$\begin{bmatrix} x^2 \\ y^2 \end{bmatrix} = \begin{bmatrix} c^3 \\ (1-c)^3 \end{bmatrix}. \quad (7)$$

Eliminating  $c$  then gives

$$x^{2/3} + y^{2/3} = 1, \quad (8)$$

which is the equation of the ASTROID. If the curve is instead represented parametrically, then

$$x = c \cos t \quad (9)$$

$$y = (1-c) \sin t. \quad (10)$$

Solving

$$\begin{aligned} \frac{\partial x}{\partial t} \frac{\partial y}{\partial c} - \frac{\partial x}{\partial c} \frac{\partial y}{\partial t} &= (-c \sin t)(-\sin t) - (\cos t)[(1-c) \cos t] \\ &= c(\sin^2 t + \cos^2 t) - \cos^2 t = c - \cos^2 t = 0 \end{aligned} \quad (11)$$

for  $c$  gives

$$c = \cos^2 t, \quad (12)$$

so substituting this back into (9) and (10) gives

$$x = (\cos^2 t) \cos t = \cos^3 t \quad (13)$$

$$y = (1 - \cos^2 t) \sin t = \sin^3 t, \quad (14)$$

the parametric equations of the ASTROID.

see also ASTROID, ELLIPSE, ENVELOPE

## Ellipse Evolute

The EVOLUTE of an ELLIPSE is given by the parametric equations

$$x = \frac{a^2 - b^2}{a} \cos^3 t \quad (1)$$

$$y = \frac{b^2 - a^2}{b} \sin^3 t, \quad (2)$$

which can be combined and written

$$\begin{aligned} (ax)^{2/3} + (by)^{2/3} &= [(a^2 - b^2) \cos^3 t]^{2/3} + [(b^2 - a^2) \sin^3 t]^{2/3} \\ &= (a^2 - b^2)^{2/3} (\cos^2 t + \sin^2 t) = (a^2 - b^2)^{2/3} = c^{4/3}, \end{aligned} \quad (3)$$

which is a stretched ASTROID called the LAMÉ CURVE.

From a point inside the EVOLUTE, four NORMALS can be drawn to the ellipse, but from a point outside, only two NORMALS can be drawn.

see also ASTROID, ELLIPSE, EVOLUTE, LAMÉ CURVE

## Ellipse Involute

From ELLIPSE, the TANGENT VECTOR is

$$\mathbf{T} = \begin{bmatrix} -a \sin t \\ b \cos t \end{bmatrix}, \quad (1)$$

and the ARC LENGTH is

$$s = a \int \sqrt{1 - e^2 \sin^2 t} dt = aE(t, e), \quad (2)$$

where  $E(t, e)$  is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND. Therefore,

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}} = \begin{bmatrix} a \cos t \\ b \sin t \end{bmatrix} - aeE(t, e) \begin{bmatrix} -a \sin t \\ b \cos t \end{bmatrix} \quad (3)$$

$$= \begin{bmatrix} a\{\cos t + aeE(t, e) \sin t\} \\ b\{\sin t - aeE(t, e) \cos t\} \end{bmatrix}. \quad (4)$$

## Ellipse Pedal Curve

The pedal curve of an ellipse with a FOCUS as the PEDAL POINT is a CIRCLE.

## Ellipsoid

A QUADRATIC SURFACE which is given in CARTESIAN COORDINATES by

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \quad (1)$$

where the semi-axes are of lengths  $a$ ,  $b$ , and  $c$ . In SPHERICAL COORDINATES, this becomes

$$\frac{r^2 \cos^2 \theta \sin^2 \phi}{a^2} + \frac{r^2 \sin^2 \theta \sin^2 \phi}{b^2} + \frac{r^2 \cos^2 \theta}{c^2} = 1. \quad (2)$$

The parametric equations are

$$x = a \cos \theta \sin \phi \quad (3)$$

$$y = b \sin \theta \sin \phi \quad (4)$$

$$z = c \cos \phi. \quad (5)$$

The SURFACE AREA (Bowman 1961, pp. 31–32) is

$$S = 2\pi c^2 + \frac{2\pi b}{\sqrt{a^2 - c^2}} [(a^2 - c^2)E(\theta) + c^2\theta], \quad (6)$$

where  $E(\theta)$  is a COMPLETE ELLIPTIC INTEGRAL OF THE SECOND KIND,

$$e_1^2 \equiv \frac{a^2 - c^2}{a^2} \quad (7)$$

$$e_2^2 \equiv \frac{b^2 - c^2}{b^2} \quad (8)$$

$$k \equiv \frac{e_2}{a_1}, \quad (9)$$

and  $\theta$  is given by inverting the expression

$$e_1 = \text{sn}(\theta, k), \quad (10)$$

where  $\text{sn}(\theta, k)$  is a JACOBI ELLIPTIC FUNCTION. The VOLUME of an ellipsoid is

$$V = \frac{4}{3}\pi abc. \quad (11)$$

If two axes are the same, the figure is called a SPHEROID (depending on whether  $c < a$  or  $c > a$ , an OBLATE SPHEROID or PROLATE SPHEROID, respectively), and if all three are the same, it is a SPHERE.

A different parameterization of the ellipsoid is the so-called stereographic ellipsoid, given by the parametric equations

$$x(u, v) = \frac{a(1 - u^2 - v^2)}{1 + u^2 + v^2} \quad (12)$$

$$y(u, v) = \frac{2bu}{1 + u^2 + v^2} \quad (13)$$

$$z(u, v) = \frac{2cv}{1 + u^2 + v^2}. \quad (14)$$

A third parameterization is the Mercator parameterization

$$x(u, v) = a \operatorname{sech} v \cos u \quad (15)$$

$$y(u, v) = b \operatorname{sech} v \sin u \quad (16)$$

$$z(u, v) = c \tanh v \quad (17)$$

(Gray 1993).

The SUPPORT FUNCTION of the ellipsoid is

$$h = \left( \frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4} \right)^{-1/2}, \quad (18)$$

and the GAUSSIAN CURVATURE is

$$K = \frac{h^4}{a^2 b^2 c^2} \quad (19)$$

(Gray 1993, p. 296).

### Ellipsoid Geodesic

An ELLIPSOID can be specified parametrically by

$$x = a \cos u \sin v \quad (1)$$

$$y = b \sin u \sin v \quad (2)$$

$$z = c \cos v. \quad (3)$$

The GEODESIC parameters are then

$$P = \sin^2 v (b^2 \cos^2 u + a^2 \sin^2 u) \quad (4)$$

$$Q = \frac{1}{4}(b^2 - a^2) \sin(2u) \sin(2v) \quad (5)$$

$$R = \cos^2 v (a^2 \cos^2 u + b^2 \sin^2 u) + c^2 \sin^2 v. \quad (6)$$

When the coordinates of a point are on the QUADRIC

$$\frac{x^2}{a} + \frac{y^2}{b} + \frac{z^2}{c} = 1 \quad (7)$$

and expressed in terms of the parameters  $p$  and  $q$  of the confocal quadrics passing through that point (in other words, having  $a+p$ ,  $b+p$ ,  $c+p$ , and  $a+q$ ,  $b+q$ ,  $c+q$  for the squares of their semimajor axes), then the equation of a GEODESIC can be expressed in the form

$$\frac{q dq}{\sqrt{q(a+q)(b+q)(c+q)(\theta+q)}} \pm \frac{p dp}{\sqrt{p(a+p)(b+p)(c+p)(\theta+p)}} = 0, \quad (8)$$

with  $\theta$  an arbitrary constant, and the ARC LENGTH element  $ds$  is given by

$$-2 \frac{ds}{pq} = \frac{dq}{\sqrt{q(a+q)(b+q)(c+q)(\theta+q)}} \pm \frac{dp}{\sqrt{p(a+p)(b+p)(c+p)(\theta+p)}}, \quad (9)$$

where upper and lower signs are taken together.

### Ellipsoidal Calculus

Ellipsoidal calculus is a method for solving problems in control and estimation theory having unknown but bounded errors in terms of sets of approximating ellipsoidal-value functions. Ellipsoidal calculus has been especially useful in the study of LINEAR PROGRAMMING.

### Ellipsoidal Coordinates

see CONFOCAL ELLIPSOIDAL COORDINATES

### Ellipsoidal Harmonic

see ELLIPSOIDAL HARMONIC OF THE FIRST KIND, ELLIPSOIDAL HARMONIC OF THE SECOND KIND

### Ellipsoidal Harmonic of the First Kind

The first solution to LAMÉ'S DIFFERENTIAL EQUATION, denoted  $E_n^m(x)$  for  $m = 1, \dots, 2n + 1$ . They are also called LAMÉ FUNCTIONS. The product of two ellipsoidal harmonics of the first kind is a SPHERICAL HARMONIC. Whittaker and Watson (1990, pp. 536–537) write

$$\Theta_p = \frac{x^2}{a^2 + \theta_p} + \frac{y^2}{b^2 + \theta_p} + \frac{z^2}{c^2 + \theta_p} - 1 \quad (1)$$

$$\Pi(\Theta) \equiv \Theta_1 \Theta_2 \cdots \Theta_m, \quad (2)$$

and give various types of ellipsoidal harmonics and their highest degree terms as

1.  $\Pi(\Theta) : 2m$
2.  $x\Pi(\Theta), y\Pi(\Theta), z\Pi(\Theta) : 2m + 1$
3.  $yz\Pi(\Theta), zx\Pi(\Theta), xy\Pi(\Theta) : 2m + 2$
4.  $xyz\Pi(\Theta) : 2m + 3$ .

A Lamé function of degree  $n$  may be expressed as

$$(\theta + a^2)^{\kappa_1} (\theta + b^2)^{\kappa_2} (\theta + c^2)^{\kappa_3} \prod_{p=1}^m (\theta - \theta_p), \quad (3)$$

where  $\kappa_i = 0$  or  $1/2$ ,  $\theta_i$  are REAL and unequal to each other and to  $-a^2$ ,  $-b^2$ , and  $-c^2$ , and

$$\frac{1}{2}n = m + \kappa_1 + \kappa_2 + \kappa_3. \quad (4)$$

Byerly (1959) uses the RECURRENCE RELATIONS to explicitly compute some ellipsoidal harmonics, which he denotes by  $K(x)$ ,  $L(x)$ ,  $M(x)$ , and  $N(x)$ ,

$$K_0(x) = 1$$

$$L_0(x) = 0$$

$$M_0(x) = 0$$

$$N_0(x) = 0$$

$$K_1(x) = x$$

$$L_1(x) = \sqrt{x^2 - b^2}$$

$$M_1(x) = \sqrt{x^2 - c^2}$$

$$N_1(x) = 0$$

$$K_2^{p1}(x) = x^2 - \frac{1}{3}[b^2 + c^2 - \sqrt{(b^2 + c^2)^2 - 3b^2c^2}]$$

$$K_2^{p2}(x) = x^2 - \frac{1}{3}[b^2 + c^2 + \sqrt{(b^2 + c^2)^2 - 3b^2c^2}]$$

$$L_2(x) = x\sqrt{x^2 - b^2}$$

$$M_2(x) = x\sqrt{x^2 - c^2}$$

$$N_2(x) = \sqrt{(x^2 - b^2)(x^2 - c^2)}$$

$$K_3^{p1}(x) = x^3 - \frac{1}{5}x[2(b^2 + c^2) - \sqrt{4(b^2 + c^2)^2 - 15b^2c^2}]$$

$$K_3^{p2}(x) = x^3 - \frac{1}{5}x[2(b^2 + c^2) + \sqrt{4(b^2 + c^2)^2 - 15b^2c^2}]$$

$$L_3^{q1}(x) = \sqrt{x^2 - b^2}[x^2 - \frac{1}{5}(b^2 + 2c^2) - \sqrt{(b^2 + 2c^2)^2 - 5b^2c^2}]$$

$$L_3^{q2}(x) = \sqrt{x^2 - b^2}[x^2 - \frac{1}{5}(b^2 + 2c^2) + \sqrt{(b^2 + 2c^2)^2 - 5b^2c^2}]$$

$$M_3^{q1}(x) = \sqrt{x^2 - c^2}[x^2 - \frac{1}{5}(2b^2 + c^2) - \sqrt{(2b^2 + c^2)^2 - 5b^2c^2}]$$

$$M_3^{q2}(x) = \sqrt{x^2 - c^2}[x^2 - \frac{1}{5}(2b^2 + c^2) + \sqrt{(2b^2 + c^2)^2 - 5b^2c^2}]$$

$$M_3^{q3}(x) = x\sqrt{(x^2 - b^2)(x^2 - c^2)}$$

### Ellipsoidal Harmonic of the Second Kind

Given by

$$F_m^p(x) = (2m+1)E_m^p(x) \times \int_x^\infty \frac{dx}{(x^2 - b^2)(x^2 - c^2)[E_m^p(x)]^2}.$$

### Elliptic Alpha Function

Elliptic alpha functions relate the complete ELLIPTIC INTEGRALS OF THE FIRST  $K(k_r)$  and SECOND KINDS  $E(k_r)$  at ELLIPTIC INTEGRAL SINGULAR VALUES  $k_r$  according to

$$\alpha(r) = \frac{E'(k_r)}{K(k_r)} - \frac{\pi}{4[K(k_r)]^2} \quad (1)$$

$$= \frac{\pi}{4[K(k_r)]^2} + \sqrt{r} - \frac{E(k_r)\sqrt{r}}{K(k_r)} \quad (2)$$

$$= \frac{\pi^{-1} - 4\sqrt{r}q \frac{d\vartheta_4(q)}{dq} \frac{1}{\vartheta_4(q)}}{\vartheta_3^4(q)}, \quad (3)$$

where  $\vartheta_3(q)$  is a THETA FUNCTION and

$$k_r = \lambda^*(r) \quad (4)$$

$$q = e^{-\pi\sqrt{r}}, \quad (5)$$

and  $\lambda^*(r)$  is the ELLIPTIC LAMBDA FUNCTION. The elliptic alpha function is related to the ELLIPTIC DELTA FUNCTION by

$$\alpha(r) = \frac{1}{2}[\sqrt{r} - \delta(r)]. \quad (6)$$

It satisfies

$$\alpha(4r) = (1 + k_r)^2 \alpha(r) - 2\sqrt{r}k_r, \quad (7)$$

and has the limit

$$\lim_{r \rightarrow \infty} \left[ \alpha(r) - \frac{1}{\pi} \right] \approx 8 \left( \sqrt{r} - \frac{1}{\pi} \right) e^{-\pi\sqrt{r}} \quad (8)$$

(Borwein *et al.* 1989). A few specific values (Borwein and Borwein 1987, p. 172) are

$$\alpha(1) = \frac{1}{2}$$

$$\alpha(2) = \sqrt{2} - 1$$

$$\alpha(3) = \frac{1}{2}(\sqrt{3} - 1)$$

$$\alpha(4) = 2(\sqrt{2} - 1)^2$$

$$\alpha(5) = \frac{1}{2}(\sqrt{5} - \sqrt{2\sqrt{5} - 2})$$

$$\alpha(6) = 5\sqrt{6} + 6\sqrt{3} - 8\sqrt{2} - 11$$

$$\alpha(7) = \frac{1}{2}(\sqrt{7} - 2)$$

$$\alpha(8) = 2(10 + 7\sqrt{2})(1 - \sqrt{\sqrt{8} - 2})^2$$

$$\alpha(9) = \frac{1}{2}[3 - 3^{3/4}\sqrt{2}(\sqrt{3} - 1)]$$

$$\alpha(10) = -103 + 72\sqrt{2} - 46\sqrt{5} + 33\sqrt{10}$$

$$\alpha(12) = 264 + 154\sqrt{3} - 188\sqrt{2} - 108\sqrt{6}$$

$$\alpha(13) = \frac{1}{2}(\sqrt{13} - \sqrt{74\sqrt{13} - 258})$$

$$\alpha(15) = \frac{1}{2}(\sqrt{15} - \sqrt{5} - 1)$$

$$\alpha(16) = \frac{4(\sqrt{8} - 1)}{(2^{1/4} + 1)^4}$$

$$\alpha(18) = -3057 + 2163\sqrt{2} + 1764\sqrt{3} - 1248\sqrt{6}$$

$$\alpha(22) = -12479 - 8824\sqrt{2} + 3762\sqrt{11} + 2661\sqrt{22}$$

$$\alpha(25) = \frac{5}{2}[1 - 25^{1/4}(7 - 3\sqrt{5})]$$

$$\alpha(27) = 3[\frac{1}{2}(\sqrt{3} + 1) - 2^{1/3}]$$

$$\alpha(30) = \frac{1}{2}\{\sqrt{30} - (2 + \sqrt{5})^2(3 + \sqrt{10})^2 \\ \times (-6 - 5\sqrt{2} - 3\sqrt{5} - 2\sqrt{10} + \sqrt{6}\sqrt{57 + 40\sqrt{2}}) \\ \times [56 + 38\sqrt{2} + \sqrt{30}(2 + \sqrt{5})(3 + \sqrt{10})]\}$$

$$\alpha(37) = \frac{1}{2}[\sqrt{37} - (171 - 25\sqrt{37})\sqrt{\sqrt{37} - 6}]$$

$$\alpha(49) = \frac{7}{2} \\ - \sqrt{7[2\sqrt{2}7^{3/4}(33011 + 12477\sqrt{7}) - 21(9567 + 3616\sqrt{7})]}$$

$$\alpha(46) = \frac{1}{2}[\sqrt{46} + (18 + 13\sqrt{2} + \sqrt{661 + 468\sqrt{2}})^2 \\ \times (18 + 13\sqrt{2} - 3\sqrt{2}\sqrt{147 + 104\sqrt{2}} + \sqrt{661 + 468\sqrt{2}}) \\ \times (200 + 14\sqrt{2} + 26\sqrt{23} + 18\sqrt{46} + \sqrt{46}\sqrt{661 + 468\sqrt{2}})]$$

$$\alpha(58) = [\frac{1}{2}(\sqrt{29} + 5)]^2(99\sqrt{29} - 444)(99\sqrt{2} - 70 - 13\sqrt{29}) \\ = 3(-40768961 + 28828008\sqrt{2} - 7570606\sqrt{29} \\ + 5353227\sqrt{58})$$

$$\alpha(64) = \frac{8[2(\sqrt{8} - 1) - (2^{1/4} - 1)^4]}{(\sqrt{\sqrt{2} + 1} + 2^{5/8})^4}.$$

J. Borwein has written an ALGORITHM which uses lattice basis reduction to provide algebraic values for  $\alpha(n)$ .

## Elliptic Cone

A CONE with ELLIPTICAL CROSS-SECTION. The parametric equations for an elliptic cone of height  $h$ , SEMI-MAJOR AXIS  $a$ , and SEMIMINOR AXIS  $b$  are

$$\begin{aligned}x &= (h - z)a \cos \theta \\y &= (h - z)b \sin \theta \\z &= z,\end{aligned}$$

where  $\theta \in [0, 2\pi)$  and  $z \in [0, h]$ .

## Elliptic Cone Point

see ISOLATED SINGULARITY

## Elliptic Curve

Informally, an elliptic curve is a type of CUBIC CURVE whose solutions are confined to a region of space which is topologically equivalent to a TORUS. Formally, an elliptic curve over a FIELD  $K$  is a nonsingular CUBIC CURVE in two variables,  $f(X, Y) = 0$ , with a  $K$ -rational point (which may be a point at infinity). The FIELD  $K$  is usually taken to be the COMPLEX NUMBERS  $\mathbb{C}$ , REALS  $\mathbb{R}$ , RATIONALS  $\mathbb{Q}$ , algebraic extensions of  $\mathbb{Q}$ ,  $p$ -ADIC NUMBERS  $\mathbb{Q}_p$ , or a FINITE FIELD.

By an appropriate change of variables, a general elliptic curve over a FIELD of CHARACTERISTIC  $\neq 2, 3$

$$Ax^3 + Bx^2y + Cxy^2 + Dy^3 + Ex^2 + Fxy + Gy^2 + Hx + Iy + J = 0, \quad (1)$$

where  $A, B, \dots$ , are elements of  $K$ , can be written in the form

$$y^2 = x^3 + ax + b, \quad (2)$$

where the right side of (2) has no repeated factors. If  $K$  has CHARACTERISTIC three, then the best that can be done is to transform the curve into

$$y^2 = x^3 + ax^2 + bx + c \quad (3)$$

(the  $x^2$  term cannot be eliminated). If  $K$  has CHARACTERISTIC two, then the situation is even worse. A general form into which an elliptic curve over any  $K$  can be transformed is called the WEIERSTRASS FORM, and is given by

$$y^2 + ay = x^3 + bx^2 + cxy + dx + e, \quad (4)$$

where  $a, b, c, d$ , and  $e$  are elements of  $K$ . Luckily,  $\mathbb{Q}$ ,  $\mathbb{R}$ , and  $\mathbb{C}$  all have CHARACTERISTIC zero.

Whereas CONIC SECTIONS can be parameterized by the rational functions, elliptic curves cannot. The simplest parameterization functions are ELLIPTIC FUNCTIONS. ABELIAN VARIETIES can be viewed as generalizations of elliptic curves.

If the underlying FIELD of an elliptic curve is algebraically closed, then a straight line cuts an elliptic curve at three points (counting multiple roots at points of tangency). If two are known, it is possible to compute the third. If two of the intersection points are  $K$ -RATIONAL, then so is the third. Let  $(x_1, y_1)$  and  $(x_2, y_2)$  be two points on an elliptic curve  $E$  with DISCRIMINANT

$$\Delta_E = -16(4a^3 + 27b^2) \quad (5)$$

satisfying

$$\Delta_E \neq 0. \quad (6)$$

A related quantity known as the  $j$ -INVARIANT of  $E$  is defined as

$$j(E) \equiv \frac{2^8 3^3 a^3}{4a^3 + 27b^2}. \quad (7)$$

Now define

$$\lambda = \begin{cases} \frac{y_1 - y_2}{x_1 - x_2} & \text{for } x_1 \neq x_2 \\ \frac{3x_1^2 + a}{2y_1} & \text{for } x_1 = x_2. \end{cases} \quad (8)$$

Then the coordinates of the third point are

$$x_3 = \lambda^2 - x_1 - x_2 \quad (9)$$

$$y_3 = \lambda(x_3 - x_1) + y_1. \quad (10)$$

For elliptic curves over  $\mathbb{Q}$ , Mordell proved that there are a finite number of integral solutions. The MORDELL-WEIL THEOREM says that the GROUP of RATIONAL

POINTS of an elliptic curve over  $\mathbb{Q}$  is finitely generated. Let the ROOTS of  $y^2$  be  $r_1, r_2$ , and  $r_3$ . The discriminant is then

$$\Delta = k(r_1 - r_2)^2(r_1 - r_3)^2(r_2 - r_3)^2. \quad (11)$$

The amazing TANIYAMA-SHIMURA CONJECTURE states that all rational elliptic curves are also modular. This fact is far from obvious, and despite the fact that the conjecture was proposed in 1955, it was not proved until 1995. Even so, Wiles' proof surprised most mathematicians, who had believed the conjecture unassailable. As a side benefit, Wiles' proof of the TANIYAMA-SHIMURA CONJECTURE also laid to rest the famous and thorny problem which had baffled mathematicians for hundreds of years, FERMAT'S LAST THEOREM.

Curves with small CONDUCTORS are listed in Swinnerton-Dyer (1975) and Cremona (1997). Methods for computing integral points (points with integral coordinates) are given in Gebel *et al.* and Stroeker and Tzanakis (1994).

#### Elliptic Curve Group Law

The GROUP of an ELLIPTIC CURVE which has been transformed to the form

$$y^2 = x^3 + ax + b$$

is the set of  $K$ -RATIONAL POINTS, including the single POINT AT INFINITY. The group law (addition) is defined as follows: Take 2  $K$ -RATIONAL POINTS  $P$  and  $Q$ . Now 'draw' a straight line through them and compute the third point of intersection  $R$  (also a  $K$ -RATIONAL POINT). Then

$$P + Q + R = 0$$

gives the identity point at infinity. Now find the inverse of  $R$ , which can be done by setting  $R = (a, b)$  giving  $-R = (a, -b)$ .

This remarkable result is only a special case of a more general procedure. Essentially, the reason is that this

type of ELLIPTIC CURVE has a single point at infinity which is an inflection point (the line at infinity meets the curve at a single point at infinity, so it must be an intersection of multiplicity three).

### Elliptic Curve Primality Proving

A class of algorithm, abbreviated ECPP, which provides certificates of primality using sophisticated results from the theory of ELLIPTIC CURVES. A detailed description and list of references are given by Atkin and Morain (1990, 1993).

Adleman and Huang (1987) designed an independent algorithm using elliptic curves of genus two.

### Elliptic Cylinder

A CYLINDER with ELLIPTICAL CROSS-SECTION. The parametric equations for an elliptic cylinder of height  $h$ , SEMIMAJOR AXIS  $a$ , and SEMIMINOR AXIS  $b$  are

$$\begin{aligned} x &= a \cos \theta \\ y &= b \sin \theta \\ z &= z, \end{aligned}$$

where  $\theta \in [0, 2\pi)$  and  $z \in [0, h]$ .

see also CONE, CYLINDER, ELLIPTIC CONE, ELLIPTIC PARABOLOID

### Elliptic Cylindrical Coordinates

The  $v$  coordinates are the asymptotic angle of confocal PARABOLA segments symmetrical about the  $x$  axis. The  $u$  coordinates are confocal ELLIPSES centered on the origin.

$$x = a \cosh u \cos v \quad (1)$$

$$y = a \sinh u \sin v \quad (2)$$

$$z = z, \quad (3)$$

where  $u \in [0, \infty)$ ,  $v \in [0, 2\pi)$ , and  $z \in (-\infty, \infty)$ . They are related to CARTESIAN COORDINATES by

$$\frac{x^2}{a^2 \cosh^2 u} + \frac{y^2}{a^2 \sinh^2 u} = 1 \quad (4)$$

$$\frac{x^2}{a^2 \cos^2 v} - \frac{y^2}{a^2 \sin^2 v} = 1. \quad (5)$$

The SCALE FACTORS are

$$h_1 = a \sqrt{\cosh^2 u \sin^2 v + \sinh^2 u \cos^2 v} \quad (6)$$

$$= a \sqrt{\frac{\cosh(2u) - \cos(2v)}{2}} \quad (7)$$

$$= a \sqrt{\sinh^2 u + \sin^2 v} \quad (8)$$

$$h_2 = a \sqrt{\sinh^2 u \sin^2 v + \sinh^2 u \cos^2 v} \quad (9)$$

$$= a \sqrt{\frac{\cosh(2u) - \cos(2v)}{2}} \quad (10)$$

$$= a \sqrt{\sinh^2 u + \sin^2 v} \quad (11)$$

$$h_3 = 1. \quad (12)$$

The LAPLACIAN is

$$\nabla^2 = \frac{1}{a^2 (\sinh^2 u + \sin^2 v)} \left( \frac{\partial^2}{\partial u^2} + \frac{\partial^2}{\partial v^2} \right) + \frac{\partial^2}{\partial z^2}. \quad (13)$$

Let

$$q_1 = \cosh u \quad (14)$$

$$q_2 = \cos v \quad (15)$$

$$q_3 = z. \quad (16)$$

Then the new SCALE FACTORS are

$$h_{q_1} = a \sqrt{\frac{q_1^2 - q_2^2}{q_1^2 - 1}} \quad (17)$$

$$h_{q_2} = a \sqrt{\frac{q_1^2 - q_2^2}{1 - q_1^2}} \quad (18)$$

$$h_{q_3} = 1. \quad (19)$$

The HELMHOLTZ DIFFERENTIAL EQUATION is SEPARABLE.

### Elliptic Fixed Point (Map)

A FIXED POINT of a LINEAR TRANSFORMATION (MAP) for which the rescaled variables satisfy

$$(\delta - \alpha)^2 + 4\beta\gamma < 0.$$

see also HYPERBOLIC FIXED POINT (MAP), LINEAR TRANSFORMATION, PARABOLIC FIXED POINT

### Elliptic Function

A doubly periodic function with periods  $2\omega_1$  and  $2\omega_2$  such that

$$f(z + 2\omega_1) = f(z + 2\omega_2) = f(z), \quad (1)$$

which is ANALYTIC and has no singularities except for POLES in the finite part of the COMPLEX PLANE. The ratio  $\omega_1/\omega_2$  must not be purely real. If this ratio is real, the function reduces to a singly periodic function if it is rational and a constant if the ratio is irrational (Jacobi, 1835).  $\omega_1$  and  $\omega_2$  are labeled such that  $\Im(\omega_2/\omega_1) > 0$ . A "cell" of an elliptic function is defined as a parallelogram region in the COMPLEX PLANE in which the function is not multi-valued. Properties obeyed by elliptic functions include

1. The number of POLES in a cell is finite.
2. The number of ROOTS in a cell is finite.
3. The sum of RESIDUES in any cell is 0.
4. LIOUVILLE'S ELLIPTIC FUNCTION THEOREM: An elliptic function with no POLES in a cell is a constant.
5. The number of zeros of  $f(z) - c$  (the "order") equals the number of POLES of  $f(z)$ .
6. The simplest elliptic function has order two, since a function of order one would have a simple irreducible POLE, which would need to have a NONZERO residue. By property (3), this is impossible.
7. Elliptic functions with a single POLE of order 2 with RESIDUE 0 are called WEIERSTRASS ELLIPTIC FUNCTIONS. Elliptic functions with two simple POLES having residues  $a_0$  and  $-a_0$  are called JACOBI ELLIPTIC FUNCTIONS.
8. Any elliptic function is expressible in terms of either WEIERSTRASS ELLIPTIC FUNCTION or JACOBI ELLIPTIC FUNCTIONS.
9. The sum of the AFFIXES of ROOTS equals the sum of the AFFIXES of the POLES.
10. An algebraic relationship exists between any two elliptic functions with the same periods.

The elliptic functions are inversions of the ELLIPTIC INTEGRALS. The two standard forms of these functions are known as JACOBI ELLIPTIC FUNCTIONS and WEIERSTRASS ELLIPTIC FUNCTIONS. JACOBI ELLIPTIC FUNCTIONS arise as solutions to differential equations of the form

$$\frac{d^2x}{dt^2} = A + Bx + Cx^2 + Dx^3, \quad (2)$$

and WEIERSTRASS ELLIPTIC FUNCTIONS arise as solutions to differential equations of the form

$$\frac{d^2x}{dt^2} = A + Bx + Cx^2. \quad (3)$$

#### Elliptic Functional

see COERCIVE FUNCTIONAL

#### Elliptic Geometry

A constant curvature NON-EUCLIDEAN GEOMETRY which replaces the PARALLEL POSTULATE with the statement "through any point in the plane, there exist no lines PARALLEL to a given line." Elliptic geometry is sometimes also called RIEMANNIAN GEOMETRY. It can be visualized as the surface of a SPHERE on which "lines" are taken as GREAT CIRCLES. In elliptic geometry, the sum of angles of a TRIANGLE is  $> 180^\circ$ .

see also EUCLIDEAN GEOMETRY, HYPERBOLIC GEOMETRY, NON-EUCLIDEAN GEOMETRY

#### Elliptic Group Modulo $p$

$E(a, b)/p$  denotes the elliptic GROUP modulo  $p$  whose elements are 1 and  $\infty$  together with the pairs of INTEGERS  $(x, y)$  with  $0 \leq x, y < p$  satisfying

$$y^2 \equiv x^3 + ax + b \pmod{p} \quad (1)$$

with  $a$  and  $b$  INTEGERS such that

$$4a^3 + 27b^2 \not\equiv 0 \pmod{p}. \quad (2)$$

Given  $(x_1, y_1)$ , define

$$(x_i, y_i) \equiv (x_1, y_1)^i \pmod{p}. \quad (3)$$

The ORDER  $h$  of  $E(a, b)/p$  is given by

$$h = 1 + \sum_{x=1}^p \left[ \left( \frac{x^3 + ax + b}{p} \right) + 1 \right], \quad (4)$$

where  $(x^3 + ax + b/p)$  is the LEGENDRE SYMBOL, although this FORMULA quickly becomes impractical. However, it has been proven that

$$p + 1 - 2\sqrt{p} \leq h(E(a, b)/p) \leq p + 1 + 2\sqrt{p}. \quad (5)$$

Furthermore, for  $p$  a PRIME  $> 3$  and and INTEGER  $n$  in the above interval, there exists  $a$  and  $b$  such that

$$h(E(a, b)/p) = n, \quad (6)$$

and the orders of elliptic GROUPS mod  $p$  are nearly uniformly distributed in the interval.

#### Elliptic Helicoid

A generalization of the HELICOID to the parametric equations

$$x(u, v) = av \cos u$$

$$y(u, v) = bv \sin u$$

$$z(u, v) = cu.$$

see also HELICOID

Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, p. 264, 1993.

### Elliptic Hyperboloid

The elliptic hyperboloid is the generalization of the HYPERBOLOID to three distinct semimajor axes. The elliptic hyperboloid of one sheet is a RULED SURFACE and has Cartesian equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1, \quad (1)$$

and parametric equations

$$x(u, v) = a\sqrt{1+u^2} \cos v \quad (2)$$

$$y(u, v) = b\sqrt{1+u^2} \sin v \quad (3)$$

$$z(u, v) = cu \quad (4)$$

for  $v \in [0, 2\pi)$ , or

$$x(u, v) = a(\cos u \mp v \sin u) \quad (5)$$

$$y(u, v) = b(\sin u \pm v \cos u) \quad (6)$$

$$z(u, v) = \pm cv, \quad (7)$$

or

$$x(u, v) = a \cosh v \cos u \quad (8)$$

$$y(u, v) = b \cosh v \sin u \quad (9)$$

$$z(u, v) = c \sinh v. \quad (10)$$

The two-sheeted elliptic hyperboloid oriented along the  $z$ -AXIS has Cartesian equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{c^2} = -1, \quad (11)$$

and parametric equations

$$x = a \sinh u \cos v \quad (12)$$

$$y = b \sinh u \sin v \quad (13)$$

$$z = c \pm \cosh u. \quad (14)$$

The two-sheeted elliptic hyperboloid oriented along the  $x$ -AXIS has Cartesian equation

$$\frac{x^2}{a^2} - \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1 \quad (15)$$

and parametric equations

$$x = a \cosh u \cosh v \quad (16)$$

$$y = b \sinh u \cosh v \quad (17)$$

$$z = c \sinh v. \quad (18)$$

see also HYPERBOLOID, RULED SURFACE

### Elliptic Integral

An elliptic integral is an INTEGRAL of the form

$$\int \frac{A(x) + B(x)\sqrt{S(x)}}{C(x) + D(x)\sqrt{S(x)}} dx, \quad (1)$$

or

$$\int \frac{A(x) dx}{B(x)\sqrt{S(x)}}, \quad (2)$$

where  $A$ ,  $B$ ,  $C$ , and  $D$  are POLYNOMIALS in  $x$  and  $S$  is a POLYNOMIAL of degree 3 or 4. Another form is

$$\int R(w, x) dx, \quad (3)$$

where  $R$  is a RATIONAL FUNCTION of  $x$  and  $y$ ,  $w^2$  is a function of  $x$  CUBIC or QUADRATIC in  $x$ ,  $R(w, x)$  contains at least one ODD POWER of  $w$ , and  $w^2$  has no repeated factors.

Elliptic integrals can be viewed as generalizations of the TRIGONOMETRIC FUNCTIONS and provide solutions to a wider class of problems. For instance, while the ARC LENGTH of a CIRCLE is given as a simple function of the parameter, computing the ARC LENGTH of an ELLIPSE requires an elliptic integral. Similarly, the position of a pendulum is given by a TRIGONOMETRIC FUNCTION as a function of time for small angle oscillations, but the full solution for arbitrarily large displacements requires the use of elliptic integrals. Many other problems in electromagnetism and gravitation are solved by elliptic integrals.

A very useful class of functions known as ELLIPTIC FUNCTIONS is obtained by inverting elliptic integrals (by analogy with the inverse trigonometric functions). ELLIPTIC FUNCTIONS (among which the JACOBI ELLIPTIC FUNCTIONS and WEIERSTRASS ELLIPTIC FUNCTION are the two most common forms) provide a powerful tool for analyzing many deep problems in NUMBER THEORY, as well as other areas of mathematics.

All elliptic integrals can be written in terms of three “standard” types. To see this, write

$$R(w, x) \equiv \frac{P(w, x)}{Q(w, x)} = \frac{wP(w, x)Q(-w, x)}{wQ(w, x)Q(-w, x)}. \quad (4)$$

But since  $w^2 = f(x)$ ,

$$Q(w, x)Q(-w, x) \equiv Q_1(w, x) = Q_1(w, x), \quad (5)$$

then

$$\begin{aligned} wP(w, x)Q(-w, x) &= A + Bx + Cw + Dx^2 + Ewx \\ &\quad + Fw^2 + Gw^2x + Hw^3x \\ &= (A + Bx + Dx^2 + Fw^2 + Gw^2x) \\ &\quad + w(c + Ex + Hw^2x + \dots) \\ &= P_1(x) + wP_2(x), \quad (6) \end{aligned}$$

so

$$R(w, x) = \frac{P_1(x) + wP_2(x)}{wQ_1(w)} = \frac{R_1(x)}{w} + R_2(x). \quad (7)$$

But any function  $\int R_2(x) dx$  can be evaluated in terms of elementary functions, so the only portion that need be considered is

$$\frac{\int R_1(x)}{w} dx. \quad (8)$$

Now, any quartic can be expressed as  $S_1S_2$  where

$$S_1 \equiv a_1x^2 + 2b_1x + c_1 \quad (9)$$

$$S_2 \equiv a_2x^2 + 2b_2x + c_2. \quad (10)$$

The COEFFICIENTS here are real, since pairs of COMPLEX ROOTS are COMPLEX CONJUGATES

$$\begin{aligned} [x - (R + Ii)][x - (R - Ii)] \\ = x^2 + x(-R + Ii - R - Ii) + (R^2 - I^2i) \\ = x^2 - 2Rx + (R^2 + I^2). \quad (11) \end{aligned}$$

If all four ROOTS are real, they must be arranged so as not to interleave (Whittaker and Watson 1990, p. 514). Now define a quantity  $\lambda$  such that  $S_1 + \lambda S_2$

$$(a_1 - \lambda a_2)x^2 - (2b_1 - 2b_2\lambda)x + (c_1 - \lambda c_2) \quad (12)$$

is a SQUARE NUMBER and

$$2\sqrt{(a_1 - \lambda a_2)(c_1 - \lambda c_2)} = 2(b_1 - b_2\lambda) \quad (13)$$

$$(a_1 - \lambda a_2)(c_1 - \lambda c_2) - (b_1 - b_2\lambda)^2 = 0. \quad (14)$$

Call the ROOTS of this equation  $\lambda_1$  and  $\lambda_2$ , then

$$\begin{aligned} S_1 - \lambda_1 S_2 &= \left[ \sqrt{(a_1 - \lambda_1 a_2)x} + \sqrt{c_1 - \lambda_1 c_2} \right]^2 \\ &= (a_1 - \lambda_1 a_2) \left( x + \sqrt{\frac{c_1 - \lambda_1 c_2}{a_1 - \lambda_1 a_2}} \right) \\ &\equiv (a_1 - \lambda_1 a_2)(x - \alpha)^2 \quad (15) \end{aligned}$$

$$\begin{aligned} S_1 - \lambda_2 S_2 &= \left[ \sqrt{(a_1 - \lambda_2 a_2)x} + \sqrt{c_1 - \lambda_2 c_2} \right]^2 \\ &= (a_1 - \lambda_2 a_2) \left( x + \sqrt{\frac{c_1 - \lambda_2 c_2}{a_1 - \lambda_2 a_2}} \right) \\ &\equiv (a_1 - \lambda_2 a_2)(x - \beta)^2. \quad (16) \end{aligned}$$

Taking (15)-(16) and  $\lambda_2(1) - \lambda_1(2)$  gives

$$\begin{aligned} S_2(\lambda_2 - \lambda_1) &= (a_1 - \lambda_1 a_2)(x - \alpha)^2 \\ &\quad - (a_1 - \lambda_2 a_2)(x - \beta)^2 \quad (17) \end{aligned}$$

$$\begin{aligned} S_1(\lambda_2 - \lambda_1) &= \lambda_2(a_1 - \lambda_1 a_2)(x - \alpha)^2 \\ &\quad - \lambda_1(a_1 - \lambda_2 a_2)(x - \beta)^2. \quad (18) \end{aligned}$$

Solving gives

$$\begin{aligned} S_1 &= \frac{a_1 - \lambda_1 a_2}{\lambda_2 - \lambda_1} (x - \alpha)^2 - \frac{a_1 - \lambda_2 a_2}{\lambda_2 - \lambda_1} (x - \beta)^2 \\ &\equiv A_1(x - \alpha)^2 + B_1(x - \beta)^2 \quad (19) \end{aligned}$$

$$\begin{aligned} S_2 &= \frac{\lambda_2(a_1 - \lambda_1 a_2)}{\lambda_2 - \lambda_1} (x - \alpha)^2 - \frac{\lambda_1(a_1 - \lambda_2 a_2)}{\lambda_2 - \lambda_1} (x - \beta)^2 \\ &\equiv A_2(x - \alpha)^2 + B_2(x - \beta)^2, \quad (20) \end{aligned}$$

so we have

$$\begin{aligned} w^2 &= S_1 S_2 \\ &= [A_1(x - \alpha)^2 + B_1(x - \beta)^2][A_2(x - \alpha)^2 + B_2(x - \beta)^2]. \quad (21) \end{aligned}$$

Now let

$$t \equiv \frac{x - \alpha}{x - \beta} \quad (22)$$

$$\begin{aligned} dy &= [(x - \beta)^{-1} - (x - \alpha)(x - \beta)^{-2}] dx \\ &= \frac{(x - \beta) - (x - \alpha)}{(x - \beta)^2} dx \\ &= \frac{\alpha - \beta}{(x - \beta)^2} dx, \quad (23) \end{aligned}$$

so

$$\begin{aligned} w^2 &= (x - \beta)^4 \left[ A_1 \left( \frac{x - \alpha}{x - \beta} \right)^2 + B_1 \right] \\ &\quad \times \left[ A_2 \left( \frac{x - \alpha}{x - \beta} \right) + B_2 \right] \\ &= (x - \beta)^4 (A_1 t^2 + B_1)(A_2 t^2 + B_2), \quad (24) \end{aligned}$$

and

$$w = (x - \beta)^2 \sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)} \quad (25)$$

$$\begin{aligned} \frac{dx}{w} &= \left[ \frac{(x - \beta)^2}{\alpha - \beta} dt \right] \frac{1}{(x - \beta)^2 \sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}} \\ &= \frac{dt}{(\alpha - \beta) \sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \quad (26) \end{aligned}$$

Now let

$$R_3(t) \equiv \frac{R_1(x)}{\alpha - \beta}, \quad (27)$$

so

$$\int \frac{R_1(x) dx}{w} = \int \frac{R_3(t) dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \quad (28)$$

Rewriting the EVEN and ODD parts

$$R_3(t) + R_3(-t) \equiv 2R_4(t^2) \quad (29)$$

$$R_3(t) - R_3(-t) \equiv 2tR_5(t^2), \quad (30)$$

gives

$$R_3(t) \equiv \frac{1}{2}(R_{\text{even}} - R_{\text{odd}}) = R_4(t^2) + tR_5(t^2), \quad (31)$$

so we have

$$\int \frac{R_1(x) dx}{w} = \int \frac{R_4(t^2) dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}} + \int \frac{R_5(t^2) t dt}{\sqrt{(A_1 t^2 + B_1)(A_2 t^2 + B_2)}}. \quad (32)$$

Letting

$$u \equiv t^2 \quad (33)$$

$$du = 2t dt \quad (34)$$

reduces the second integral to

$$\frac{1}{2} \int \frac{R_5(u) du}{\sqrt{(A_1 u + B_1)(A_2 u + B_2)}}, \quad (35)$$

which can be evaluated using elementary functions. The first integral can then be reduced by INTEGRATION BY PARTS to one of the three Legendre elliptic integrals (also called Legendre-Jacobi ELLIPTIC INTEGRALS), known as incomplete elliptic integrals of the first, second, and third kind, denoted  $F(\phi, k)$ ,  $E(\phi, k)$ , and  $\Pi(n; \phi, k)$ , respectively (von Kármán and Biot 1940, Whittaker and Watson 1990, p. 515). If  $\phi = \pi/2$ , then the integrals are called complete elliptic integrals and are denoted  $K(k)$ ,  $E(k)$ ,  $\Pi(n; k)$ .

Incomplete elliptic integrals are denoted using a MODULUS  $k$ , PARAMETER  $m \equiv k^2$ , or MODULAR ANGLE  $\alpha \equiv \sin^{-1} k$ . An elliptic integral is written  $I(\phi|m)$  when the PARAMETER is used,  $I(\phi, k)$  when the MODULUS is used, and  $I(\phi|\alpha)$  when the MODULAR ANGLE is used. Complete elliptic integrals are defined when  $\phi = \pi/2$  and can be expressed using the expansion

$$(1 - k^2 \sin^2 \theta)^{-1/2} = \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \sin^{2n} \theta. \quad (36)$$

An elliptic integral in standard form

$$\int_a^x \frac{dx}{\sqrt{f(x)}}, \quad (37)$$

where

$$f(x) = a_4 x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0, \quad (38)$$

can be computed analytically (Whittaker and Watson 1990, p. 453) in terms of the WEIERSTRASS ELLIPTIC FUNCTION with invariants

$$g_2 = a_0 a_4 - 4a_1 a_3 + 3a_2^2 \quad (39)$$

$$g_3 = a_0 a_2 a_4 - 2a_1 a_2 a_3 - a_4 a_1^2 - a_3^2 a_0. \quad (40)$$

If  $a \equiv x_0$  is a root of  $f(x) = 0$ , then the solution is

$$x = x_0 + \frac{1}{4} f'(x_0) [\wp(z; g_2, g_3) - \frac{1}{24} f''(x_0)]^{-1}. \quad (41)$$

For an arbitrary lower bound,

$$x = a + \frac{\sqrt{f(a)} \wp'(z) + \frac{1}{2} f'(a) [\wp(z) - \frac{1}{24} f''(a)] + \frac{1}{24} f(a) f'''(a)}{2[\wp(z) - \frac{1}{24} f''(a)]^2 - \frac{1}{48} f(a) f^{(4)}(a)}, \quad (42)$$

where  $\wp(z) \equiv \wp(z; g_2, g_3)$  is a WEIERSTRASS ELLIPTIC FUNCTION.

A generalized elliptic integral can be defined by the function

$$T(a, b) \equiv \frac{2}{\pi} \int_0^{\pi/2} \frac{d\theta}{\sqrt{a^2 \cos^2 \theta + b^2 \sin^2 \theta}} \quad (43)$$

$$= \frac{2}{\pi} \int_0^{\pi/2} \int \frac{d\theta}{\cos \theta \sqrt{a^2 + b^2 \tan^2 \theta}} \quad (44)$$

(Borwein and Borwein 1987). Now let

$$t \equiv b \tan \theta \quad (45)$$

$$dt = b \sec^2 \theta d\theta. \quad (46)$$

But

$$\sec \theta = \sqrt{1 + \tan^2 \theta}, \quad (47)$$

so

$$\begin{aligned} dt &= \frac{b}{\cos \theta} \sec \theta d\theta = \frac{b}{\cos \theta} \sqrt{1 + \tan^2 \theta} d\theta \\ &= \frac{b}{\cos \theta} \sqrt{1 + \left(\frac{t}{b}\right)^2} d\theta \\ &= \frac{d\theta}{\cos \theta} \sqrt{b^2 + t^2}, \end{aligned} \quad (48)$$

and

$$\frac{d\theta}{\cos \theta} = \frac{dt}{\sqrt{b^2 + t^2}}, \quad (49)$$

and the equation becomes

$$\begin{aligned} T(a, b) &= \frac{2}{\pi} \int_0^{\infty} \frac{dt}{\sqrt{(a^2 + t^2)(b^2 + t^2)}} \\ &= \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{dt}{\sqrt{(a^2 + t^2)(b^2 + t^2)}}. \end{aligned} \quad (50)$$

Now we make the further substitution  $u \equiv \frac{1}{2}(t - ab/t)$ . The differential becomes

$$du = \frac{1}{2}(1 + ab/t^2) dt, \quad (51)$$

but  $2u = t - ab/t$ , so

$$2u/t = 1 - ab/t^2 \quad (52)$$

$$ab/t^2 = 1 - 2u/t \quad (53)$$

and

$$1 + ab/t^2 = 2 - 2u/t = 2(1 - u/t). \quad (54)$$

However, the left side is always positive, so

$$1 + ab/t^2 = 2 - 2u/t = 2|1 - u/t| \quad (55)$$

and the differential is

$$dt = \frac{du}{\left|1 - \frac{u}{t}\right|}. \quad (56)$$

We need to take some care with the limits of integration. Write (50) as

$$\int_{-\infty}^{\infty} f(t) dt = \int_{-\infty}^{0^-} f(t) dt + \int_{0^+}^{\infty} f(t) dt. \quad (57)$$

Now change the limits to those appropriate for the  $u$  integration

$$\int_{-\infty}^{\infty} g(u) du + \int_{-\infty}^{\infty} g(u) du = 2 \int_{-\infty}^{\infty} g(u) du, \quad (58)$$

so we have picked up a factor of 2 which must be included. Using this fact and plugging (56) in (50) therefore gives

$$T(a, b) = \frac{2}{\pi} \int_{-\infty}^{\infty} \frac{du}{\left|1 - \frac{u}{t}\right| \sqrt{a^2 b^2 + (a^2 + b^2)t^2 + t^4}}. \quad (59)$$

Now note that

$$u^2 = \frac{t^4 - 2abt^2 + a^2b^2}{4t^2} \quad (60)$$

$$4u^2t^2 = t^4 - 2abt^2 + 2abt^2 \quad (61)$$

$$a^2b^2 + t^4 = 4u^2t^2 + 2abt^2. \quad (62)$$

Plug (62) into (59) to obtain

$$\begin{aligned} T(a, b) &= \frac{2}{\pi} \int_{-\infty}^{\infty} \frac{du}{\left|1 - \frac{u}{t}\right| \sqrt{4u^2t^2 + 2abt^2 + (a^2 + b^2)t^2}} \\ &= \frac{2}{\pi} \int_{-\infty}^{\infty} \frac{du}{|t - u| \sqrt{4u^2 + (a + b)^2}}. \end{aligned} \quad (63)$$

But

$$2ut = t^2 - ab \quad (64)$$

$$t^2 - 2ut - ab = 0 \quad (65)$$

$$t = \frac{1}{2}(2u \pm \sqrt{4u^2 + 4ab}) = u \pm \sqrt{u^2 + ab}, \quad (66)$$

so

$$t - u = \pm \sqrt{u^2 + ab}, \quad (67)$$

and (63) becomes

$$\begin{aligned} T(a, b) &= \frac{2}{\pi} \int_{-\infty}^{\infty} \frac{du}{\sqrt{[4u^2 + (a + b)^2](u^2 + ab)}} \\ &= \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{du}{\sqrt{\left[u^2 + \left(\frac{a+b}{2}\right)^2\right](u^2 + ab)}}. \end{aligned} \quad (68)$$

We have therefore demonstrated that

$$T(a, b) = T\left(\frac{1}{2}(a + b), \sqrt{ab}\right). \quad (69)$$

We can thus iterate

$$a_{i+1} = \frac{1}{2}(a_i + b_i) \quad (70)$$

$$b_{i+1} = \sqrt{a_i b_i}, \quad (71)$$

as many times as we wish, without changing the value of the integral. But this iteration is the same as and therefore converges to the ARITHMETIC-GEOMETRIC MEAN, so the iteration terminates at  $a_i = b_i = M(a_0, b_0)$ , and we have

$$\begin{aligned} T(a_0, b_0) &= T(M(a_0, b_0), M(a_0, b_0)) \\ &= \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{dt}{M^2(a_0, b_0) + t^2} \\ &= \frac{1}{\pi M(a_0, b_0)} \left[ \tan^{-1} \left( \frac{t}{M(a_0, b_0)} \right) \right]_{-\infty}^{\infty} \\ &= \frac{1}{\pi M(a_0, b_0)} \left[ \frac{\pi}{2} - \left( \frac{\pi}{2} \right) \right] \\ &= \frac{1}{M(a_0, b_0)}. \end{aligned} \quad (72)$$

Complete elliptic integrals arise in finding the arc length of an ELLIPSE and the period of a pendulum. They also arise in a natural way from the theory of THETA FUNCTIONS. Complete elliptic integrals can be computed using a procedure involving the ARITHMETIC-GEOMETRIC MEAN. Note that

$$\begin{aligned} T(a, b) &\equiv \frac{2}{\pi} \int_0^{\pi/2} \frac{d\theta}{\sqrt{a^2 \cos^2 \theta + b^2 \sin^2 \theta}} \\ &= \frac{2}{\pi} \int_0^{\pi/2} \frac{d\theta}{a \sqrt{\cos^2 \theta + \left(\frac{b}{a}\right)^2 \sin^2 \theta}} \\ &= \frac{2}{a\pi} \int_0^{\pi/2} \frac{d\theta}{\sqrt{1 - \left(1 - \frac{b^2}{a^2}\right) \sin^2 \theta}}. \end{aligned} \quad (73)$$

So we have

$$T(a, b) = \frac{2}{a\pi} K\left(1 - \frac{b^2}{a^2}\right) = \frac{1}{M(a, b)}, \quad (74)$$

where  $K(k)$  is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND. We are free to let  $a \equiv a_0 \equiv 1$  and  $b \equiv b_0 \equiv k'$ , so

$$\frac{2}{\pi} K(\sqrt{1 - k'^2}) = \frac{2}{\pi} K(k) = \frac{1}{M(1, k')}, \quad (75)$$

since  $k \equiv \sqrt{1 - k'^2}$ , so

$$K(k) = \frac{\pi}{2M(1, k')}. \quad (76)$$

But the ARITHMETIC-GEOMETRIC MEAN is defined by

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1}) \quad (77)$$

$$b_i = \sqrt{a_{i-1}b_{i-1}} \quad (78)$$

$$c_i = \begin{cases} \frac{1}{2}(a_{i-1} - b_{i-1}) & i > 0 \\ \sqrt{a_0^2 - b_0^2} & i = 0, \end{cases} \quad (79)$$

where

$$c_{n-1} = \frac{1}{2}a_n - b_n = \frac{c_n^2}{4a_{n+1}} \leq \frac{c_n^2}{4M(a_0, b_0)}, \quad (80)$$

so we have

$$K(k) = \frac{\pi}{2a_N}, \quad (81)$$

where  $a_N$  is the value to which  $a_n$  converges. Similarly, taking instead  $a'_0 = 1$  and  $b'_0 = k$  gives

$$K'(k) = \frac{\pi}{2a'_N}. \quad (82)$$

Borwein and Borwein (1987) also show that defining

$$U(a, b) \equiv \frac{\pi}{2} \int_0^{\pi/2} \sqrt{a^2 \cos^2 \theta + b^2 \sin^2 \theta} d\theta = aE'\left(\frac{b}{a}\right) \quad (83)$$

leads to

$$2U(a_{n+1}, b_{n+1}) - U(a_n, b_n) = a_n b_n T(a_n, b_n), \quad (84)$$

so

$$\frac{K(k) - E(k)}{K(k)} = \frac{1}{2}(c_0^2 + 2c_1^2 + 2^2c_2^2 + \dots + 2^n c_n^2) \quad (85)$$

for  $a_0 \equiv 1$  and  $b_0 \equiv k'$ , and

$$\frac{K'(k) - E'(k)}{K'(k)} = \frac{1}{2}(c_0'^2 + 2c_1'^2 + 2^2c_2'^2 + \dots + 2^n c_n'^2). \quad (86)$$

The elliptic integrals satisfy a large number of identities. The complementary functions and moduli are defined by

$$K'(k) \equiv K(\sqrt{1 - k^2}) = K(k'). \quad (87)$$

Use the identity of generalized elliptic integrals

$$T(a, b) = T\left(\frac{1}{2}(a + b), \sqrt{ab}\right) \quad (88)$$

to write

$$\begin{aligned} \frac{1}{a} K\left(\sqrt{1 - \frac{b^2}{a^2}}\right) &= \frac{2}{a+b} K\left(\sqrt{1 - \frac{4ab}{(a+b)^2}}\right) \\ &= \frac{2}{a+b} K\left(\sqrt{\frac{a^2 + b^2 - 2ab}{(a+b)^2}}\right) \\ &= \frac{2}{a+b} K\left(\frac{a-b}{a+b}\right) \end{aligned} \quad (89)$$

$$K\left(\sqrt{1 - \frac{b^2}{a^2}}\right) = \frac{2}{1 + \frac{b}{a}} K\left(\frac{1 - \frac{b}{a}}{1 + \frac{b}{a}}\right). \quad (90)$$

Define

$$k' \equiv \frac{b}{a}, \quad (91)$$

and use

$$k \equiv \sqrt{1 - k'^2}, \quad (92)$$

so

$$K(k) = \frac{2}{1+k'} K\left(\frac{1-k'}{1+k'}\right). \quad (93)$$

Now letting  $l \equiv (1 - k')/(1 + k')$  gives

$$l(1 + k') = 1 - k' \Rightarrow k'(l + 1) = 1 - l \quad (94)$$

$$k' = \frac{1-l}{1+l} \quad (95)$$

$$\begin{aligned} k &= \sqrt{1 - k'^2} = \sqrt{1 - \left(\frac{1-l}{1+l}\right)^2} \\ &= \sqrt{\frac{(1+l)^2 - (1-l)^2}{(1+l)^2}} = \frac{2\sqrt{l}}{1+l}, \end{aligned} \quad (96)$$

and

$$\begin{aligned} \frac{1}{2}(1 + k') &= \frac{1}{2}\left(1 + \frac{1-l}{1+l}\right) = \frac{1}{2}\left[\frac{(1+l) + (1-l)}{1+l}\right] \\ &= \frac{1}{1+l}. \end{aligned} \quad (97)$$

Writing  $k$  instead of  $l$ ,

$$K(k) = \frac{1}{k+1} K\left(\frac{2\sqrt{k}}{1+k}\right). \quad (98)$$

Similarly, from Borwein and Borwein (1987),

$$E(k) = \frac{1+k}{2} E\left(\frac{2\sqrt{k}}{1+k}\right) + \frac{k'^2}{2} K(k) \quad (99)$$

$$E(k) = (1+k') E\left(\frac{1-k'}{1+k'}\right) - k' K(k). \quad (100)$$

Expressions in terms of the complementary function can be derived from interchanging the moduli and their complements in (93), (98), (99), and (100).

$$\begin{aligned} K'(k) &= K(k') = \frac{2}{1+k} K\left(\frac{1-k}{1+k}\right) \\ &= \frac{2}{1+k} K'\left(\sqrt{1 - \left(\frac{1-k}{1+k}\right)^2}\right) \\ &= \frac{2}{1+k} K'\left(\frac{2\sqrt{k}}{1+k}\right) \end{aligned} \quad (101)$$

$$K'(k) = \frac{1}{1+k'} K\left(\frac{2\sqrt{k'}}{1+k'}\right) = \frac{1}{1+k'} K'\left(\frac{1-k'}{1+k'}\right), \quad (102)$$

and

$$E'(k) = (1+k) E'\left(\frac{2\sqrt{k}}{1+k}\right) - k K'(k) \quad (103)$$

$$E'(k) = \left(\frac{1+k'}{2}\right) E'\left(\frac{1-k'}{1+k'}\right) + \frac{k^2}{2} K'(k). \quad (104)$$

Taking the ratios

$$\frac{K'(k)}{K(k)} = 2 \frac{K'\left(\frac{2\sqrt{k}}{1+k}\right)}{K\left(\frac{2\sqrt{k}}{1+k}\right)} = \frac{1}{2} \frac{K'\left(\frac{1-k'}{1+k'}\right)}{K\left(\frac{1-k'}{1+k'}\right)} \quad (105)$$

gives the MODULAR EQUATION of degree 2. It is also true that

$$K(x) = \frac{4}{(1+\sqrt{x'})^2} K\left(\left[\frac{1-\sqrt[4]{1-x^4}}{1+\sqrt[4]{1-x^4}}\right]^2\right). \quad (106)$$

#### Elliptic Integral of the First Kind

Let the MODULUS  $k$  satisfy  $0 < k^2 < 1$ . (This may also be written in terms of the PARAMETER  $m \equiv k^2$  or MODULAR ANGLE  $\alpha \equiv \sin^{-1} k$ .) The incomplete elliptic integral of the first kind is then defined as

$$F(\phi, k) = \int_0^\phi \frac{d\theta}{\sqrt{1 - k^2 \sin^2 \theta}}. \quad (1)$$

Let

$$t \equiv \sin \theta \quad (2)$$

$$dt = \cos \theta d\theta = \sqrt{1 - t^2} d\theta \quad (3)$$

$$\begin{aligned} F(\phi, k) &= \int_0^{\sin \phi} \frac{1}{\sqrt{1 - k^2 t^2}} \frac{dt}{\sqrt{1 - t^2}} \\ &= \int_0^{\sin \phi} \frac{dt}{\sqrt{(1 - k^2 t^2)(1 - t^2)}}. \end{aligned} \quad (4)$$

Let

$$v \equiv \tan \theta \quad (5)$$

$$dv \equiv \sec^2 \theta d\theta = (1 + v^2) d\theta, \quad (6)$$

so the integral can also be written as

$$\begin{aligned} F(\phi, k) &= \int_0^{\tan \phi} \frac{1}{\sqrt{1 - k^2 \frac{v^2}{1+v^2}}} \frac{du}{1+v^2} \\ &= \int_0^{\tan \phi} \frac{dv}{\sqrt{1+v^2} \sqrt{(1+v^2) - k^2 v^2}} \end{aligned} \quad (7)$$

$$= \int_0^{\tan \phi} \frac{dv}{\sqrt{(1+v^2)(1+k'v^2)}}, \quad (8)$$

where  $k'^2 \equiv 1 - k^2$  is the complementary MODULUS.

The integral

$$I = \frac{1}{\sqrt{2}} \int_0^{\theta_0} \frac{d\theta}{\sqrt{\cos \theta - \cos \theta_0}}, \quad (9)$$

which arises in computing the period of a pendulum, is also an elliptic integral of the first kind. Use

$$\cos \theta = 1 - 2 \sin^2(\tfrac{1}{2}\theta) \quad (10)$$

$$\sin(\tfrac{1}{2}\theta) = \sqrt{\frac{1 - \cos \theta}{2}} \quad (11)$$

to write

$$\begin{aligned} \sqrt{\cos \theta - \cos \theta_0} &= \sqrt{1 - 2 \sin^2(\tfrac{1}{2}\theta) - \cos \theta_0} \\ &= \sqrt{1 - \cos \theta_0} \sqrt{1 - \frac{2}{1 - \cos \theta_0} \sin^2(\tfrac{1}{2}\theta)} \\ &= \sqrt{2} \sin(\tfrac{1}{2}\theta_0) \sqrt{1 - \csc^2(\tfrac{1}{2}\theta_0) \sin^2(\tfrac{1}{2}\theta)}, \end{aligned} \quad (12)$$

so

$$I = \frac{1}{2} \int_0^{\theta_0} \frac{d\theta}{\sin(\tfrac{1}{2}\theta_0) \sqrt{1 - \csc^2(\tfrac{1}{2}\theta_0) \sin^2(\tfrac{1}{2}\theta)}}. \quad (13)$$

Now let

$$\sin(\tfrac{1}{2}\theta) = \sin(\tfrac{1}{2}\theta_0) \sin \phi, \quad (14)$$

so the angle  $\theta$  is transformed to

$$\phi = \sin^{-1} \left( \frac{\sin \theta}{\sin \theta_0} \right), \quad (15)$$

which ranges from 0 to  $\pi/2$  as  $\theta$  varies from 0 to  $\theta_0$ . Taking the differential gives

$$\tfrac{1}{2} \cos(\tfrac{1}{2}\theta) d\theta = \sin(\tfrac{1}{2}\theta_0) \cos \phi d\phi, \quad (16)$$

or

$$\tfrac{1}{2} \sqrt{1 - \sin^2(\tfrac{1}{2}\theta_0) \sin^2 \phi} d\theta = \sin(\tfrac{1}{2}\theta_0) \cos \phi d\phi. \quad (17)$$

Plugging this in gives

$$\begin{aligned} I &= \int_0^{\pi/2} \frac{1}{\sqrt{1 - \sin^2(\tfrac{1}{2}\theta_0) \sin^2 \phi}} \frac{\sin(\tfrac{1}{2}\theta_0) \cos \phi d\phi}{\sin(\tfrac{1}{2}\theta_0) \sqrt{1 - \sin^2 \phi}} \\ &= \int_0^{\pi/2} \frac{d\phi}{\sqrt{1 - \sin^2(\tfrac{1}{2}\theta_0) \sin^2 \phi}} = K(\sin(\tfrac{1}{2}\theta_0)), \end{aligned} \quad (18)$$

so

$$I = \frac{1}{\sqrt{2}} \int_0^{\theta_0} \frac{d\theta}{\sqrt{\cos \theta - \cos \theta_0}} = K(\sin(\tfrac{1}{2}\theta_0)). \quad (19)$$

Making the slightly different substitution  $\phi = \theta/2$ , so  $d\theta = 2 d\phi$  leads to an equivalent, but more complicated expression involving an *incomplete* elliptic function of the first kind,

$$\begin{aligned} I &= 2 \frac{1}{\sqrt{2}} \frac{1}{\sqrt{2}} \csc(\tfrac{1}{2}\theta_0) \int_0^{\theta_0} \frac{d\phi}{\sqrt{1 - \csc^2(\tfrac{1}{2}\theta_0) \sin^2 \phi}} \\ &= \csc(\tfrac{1}{2}\theta_0) F(\tfrac{1}{2}\theta_0, \csc(\tfrac{1}{2}\theta_0)). \end{aligned} \quad (20)$$

Therefore, we have proven the identity

$$\csc x F(x, \csc x) = K(\sin x). \quad (21)$$

The complete elliptic integral of the first kind, illustrated above as a function of  $m = k^2$ , is defined by

$$K(k) \equiv F(\tfrac{1}{2}\pi, k) \quad (22)$$

$$= \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \int_0^{2\pi} \sin^{2n} \theta d\theta \quad (23)$$

$$= \tfrac{1}{2} \pi {}_2F_1(q) \quad (24)$$

$$= \sum_{n=0}^{\infty} \frac{(2n-1)!!}{(2n)!!} k^{2n} \frac{\pi}{2} \frac{(2n-1)!!}{(2n)!!}$$

$$= \frac{\pi}{2} \sum_{n=0}^{\infty} \left[ \frac{(2n-1)!!}{(2n)!!} \right]^2 k^{2n} \quad (25)$$

$$= \tfrac{1}{2} \pi {}_2F_1(\tfrac{1}{2}, \tfrac{1}{2}, 1; k^2) \quad (26)$$

$$= \frac{\pi}{2\sqrt{1-k^2}} P_{-1/2} \left( \frac{1+k^2}{1-k^2} \right), \quad (27)$$

where

$$q = e^{-\pi K'(k)/K(k)} \quad (28)$$

is the NOME (for  $|q| < 1$ ),  ${}_2F_1(a, b; c; x)$  is the HYPERGEOMETRIC FUNCTION, and  $P_n(x)$  is a LEGENDRE POLYNOMIAL.  $K(k)$  satisfies the LEGENDRE RELATION

$$E(k)K'(k) + E'(k)K(k) - K(k)K'(k) = \tfrac{1}{2}\pi, \quad (29)$$

where  $E(k)$  and  $K(k)$  are complete elliptic integrals of the first and SECOND KINDS, and  $E'(k)$  and  $K'(k)$  are the complementary integrals. The modulus  $k$  is often suppressed for conciseness, so that  $E(k)$  and  $K(k)$  are often simply written  $E$  and  $K$ , respectively.

The DERIVATIVE of  $K(k)$  is

$$\frac{dK}{dk} \equiv \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-k'^2t^2)}} = \frac{E(k)}{k(1-k^2)} - \frac{K(k)}{k} \quad (30)$$

$$\frac{d}{dk} \left( k k'^2 \frac{dK}{dk} \right) = kK, \quad (31)$$

so

$$E = k(1-k^2) \left( \frac{dK}{dk} + \frac{K}{k} \right) = (1-k^2) \left( k \frac{dK}{dk} + K \right) \quad (32)$$

(Whittaker and Watson 1990, pp. 499 and 521).

### Elliptic Integral of the Second Kind

Let the MODULUS  $k$  satisfy  $0 < k^2 < 1$ . (This may also be written in terms of the PARAMETER  $m \equiv k^2$  or MODULAR ANGLE  $\alpha \equiv \sin^{-1} k$ .) The incomplete elliptic integral of the second kind is then defined as

$$E(\phi, k) \equiv \int_0^\phi \sqrt{1 - k^2 \sin^2 \theta} d\theta. \quad (1)$$

A generalization replacing  $\sin \theta$  with  $\sinh \theta$  gives

$$-iE(i\phi, -k) = \int_0^\phi \sqrt{1 - k^2 \sinh^2 \theta} d\theta. \quad (2)$$

To place the elliptic integral of the second kind in a slightly different form, let

$$t \equiv \sin \theta \quad (3)$$

$$dt = \cos \theta d\theta = \sqrt{1 - t^2} d\theta, \quad (4)$$

so the elliptic integral can also be written as

$$\begin{aligned} E(\phi, k) &= \int_0^{\sin \phi} \sqrt{1 - k^2 t^2} \frac{dt}{\sqrt{1 - t^2}} \\ &= \int_0^{\sin \phi} \sqrt{\frac{1 - k^2 t^2}{1 - t^2}} dt. \end{aligned} \quad (5)$$

The complete elliptic integral of the second kind, illustrated above as a function of the PARAMETER  $m$ , is defined by

$$E(k) \equiv E\left(\frac{1}{2}\pi, k\right) \quad (6)$$

$$= \frac{\pi}{2} \left\{ 1 - \sum_{n=1}^{\infty} \left[ \frac{(2n-1)!!}{(2n)!!} \right]^2 \frac{k^{2n}}{2n-1} \right\} \quad (7)$$

$$= \frac{1}{2}\pi {}_2F_1\left(-\frac{1}{2}, \frac{1}{2}, 1; k^2\right) \quad (8)$$

$$= \int_0^K dn^2 u du, \quad (9)$$

where  ${}_2F_1(a, b; c; x)$  is the HYPERGEOMETRIC FUNCTION and  $dn u$  is a JACOBI ELLIPTIC FUNCTION. The complete elliptic integral of the second kind satisfies the LEGENDRE RELATION

$$E(k)K'(k) + E'(k)K(k) - K(k)K'(k) = \frac{1}{2}\pi, \quad (10)$$

where  $E$  and  $K$  are complete ELLIPTIC INTEGRALS OF THE FIRST and second kinds, and  $E'$  and  $K'$  are the complementary integrals. The DERIVATIVE is

$$\frac{dE}{dk} = \frac{E(k) - K(k)}{k} \quad (11)$$

(Whittaker and Watson 1990, p. 521). If  $k_r$  is a singular value (i.e.,

$$k_r = \lambda^*(r), \quad (12)$$

where  $\lambda^*$  is the ELLIPTIC LAMBDA FUNCTION), and  $K(k_r)$  and the ELLIPTIC ALPHA FUNCTION  $\alpha(r)$  are also known, then

$$E(k) = \frac{K(k)}{\sqrt{r}} \left[ \frac{\pi}{3[K(k)]^2} - \alpha(r) \right] + K(k). \quad (13)$$

see also ELLIPTIC INTEGRAL OF THE FIRST KIND, ELLIPTIC INTEGRAL OF THE THIRD KIND, ELLIPTIC INTEGRAL SINGULAR VALUE

### Elliptic Integral of the Third Kind

Let  $0 < k^2 < 1$ . The incomplete elliptic integral of the third kind is then defined as

$$\Pi(n; \phi, k) = \int_0^\phi \frac{d\theta}{(1 - n \sin^2 \theta) \sqrt{1 - k^2 \sin^2 \theta}} \quad (1)$$

$$= \int_0^{\sin \phi} \frac{dt}{(1 - nt^2) \sqrt{(1 - t^2)(1 - k^2 t^2)}}, \quad (2)$$

where  $n$  is a constant known as the CHARACTERISTIC.

The complete elliptic integral of the second kind

$$\Pi(n|m) = \Pi(n; \frac{1}{2}\pi|m) \quad (3)$$

is illustrated above.

### Elliptic Integral Singular Value

When the MODULUS  $k$  has a singular value, the complete elliptic integrals may be computed in analytic form in terms of GAMMA FUNCTIONS. Abel (quoted in Whittaker and Watson 1990, p. 525) proved that whenever

$$\frac{K'(k)}{K(k)} = \frac{a + b\sqrt{n}}{c + d\sqrt{n}}, \quad (1)$$

where  $a, b, c, d$ , and  $n$  are INTEGERS,  $K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and  $K'(k) \equiv K(\sqrt{1 - k^2})$  is the complementary complete ELLIPTIC INTEGRAL OF THE FIRST KIND, then the MODULUS  $k$  is the ROOT of an algebraic equation with INTEGER COEFFICIENTS.

A MODULUS  $k_r$  such that

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r}, \quad (2)$$

is called a singular value of the elliptic integral. The ELLIPTIC LAMBDA FUNCTION  $\lambda^*(r)$  gives the value of  $k_r$ . Selberg and Chowla (1967) showed that  $K(\lambda^*(r))$  and  $E(\lambda^*(r))$  are expressible in terms of a finite number of GAMMA FUNCTIONS. The complete ELLIPTIC INTEGRALS OF THE SECOND KIND  $E(k_r)$  and  $E'(k_r)$  can be expressed in terms of  $K(k_r)$  and  $K'(k_r)$  with the aid of the ELLIPTIC ALPHA FUNCTION  $\alpha(r)$ .

The following table gives the values of  $K(k_r)$  for small integral  $r$  in terms of GAMMA FUNCTIONS.

$$K(k_1) = \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}}$$

$$K(k_2) = \frac{\sqrt{\sqrt{2} + 1} \Gamma(\frac{1}{8}) \Gamma(\frac{3}{8})}{2^{13/4} \sqrt{\pi}}$$

$$K(k_3) = \frac{3^{1/4} \Gamma^3(\frac{1}{3})}{2^{7/3} \pi}$$

$$K(k_4) = \frac{(\sqrt{2} + 1) \Gamma^2(\frac{1}{4})}{2^{7/2} \sqrt{\pi}}$$

$$K(k_5) = (\sqrt{5} + 2)^{1/4} \sqrt{\frac{\Gamma(\frac{1}{20}) \Gamma(\frac{3}{20}) \Gamma(\frac{7}{20}) \Gamma(\frac{9}{20})}{160\pi}}$$

$$K(k_6) = \sqrt{(\sqrt{2} - 1)(\sqrt{3} + \sqrt{2})(2 + \sqrt{3})} \times \sqrt{\frac{\Gamma(\frac{1}{24}) \Gamma(\frac{5}{24}) \Gamma(\frac{7}{24}) \Gamma(\frac{11}{24})}{384\pi}}$$

$$K(k_7) = \frac{\Gamma(\frac{1}{7}) \Gamma(\frac{2}{7}) \Gamma(\frac{4}{7})}{7^{1/4} \cdot 4\pi}$$

$$K(k_8) = \sqrt{\frac{2\sqrt{2} + \sqrt{1 + 5\sqrt{2}}}{4\sqrt{2}}} \frac{(\sqrt{2} + 1)^{1/4} \Gamma(\frac{1}{8}) \Gamma(\frac{3}{8})}{8\sqrt{\pi}}$$

$$\begin{aligned}
 K(k_9) &= \frac{3^{1/4} \sqrt{2 + \sqrt{3}}}{12\sqrt{\pi} \Gamma^2(\frac{1}{4})} \\
 K(k_{10}) &= \sqrt{(2 + 3\sqrt{2} + \sqrt{5})} \\
 &\quad \times \sqrt{\frac{\Gamma(\frac{1}{40})\Gamma(\frac{7}{40})\Gamma(\frac{9}{40})\Gamma(\frac{11}{40})\Gamma(\frac{13}{40})\Gamma(\frac{19}{40})\Gamma(\frac{23}{40})\Gamma(\frac{27}{40})}{2560\pi^3}} \\
 K(k_{11}) &= [2 + (17 + 3\sqrt{33})^{1/3} - (3\sqrt{33} - 17)^{1/3}]^2 \\
 &\quad \times \frac{\Gamma(\frac{1}{11})\Gamma(\frac{3}{11})\Gamma(\frac{4}{11})\Gamma(\frac{5}{11})\Gamma(\frac{9}{11})}{11^{1/4} 144\pi^2} \\
 K(k_{12}) &= \frac{3^{1/4}(\sqrt{2} + 1)(\sqrt{3} + \sqrt{2})\sqrt{2 - \sqrt{3}}\Gamma^3(\frac{1}{3})}{2^{13/3}\pi} \\
 K(k_{13}) &= \frac{(18 + 5\sqrt{13})^{1/4}}{\sqrt{6656\pi^5}} \\
 &\quad \times \sqrt{\frac{\Gamma(\frac{1}{52})\Gamma(\frac{7}{52})\Gamma(\frac{9}{52})\Gamma(\frac{11}{52})\Gamma(\frac{15}{52})\Gamma(\frac{17}{52})}{\Gamma(\frac{19}{52})\Gamma(\frac{25}{52})\Gamma(\frac{29}{52})\Gamma(\frac{31}{52})\Gamma(\frac{47}{52})\Gamma(\frac{49}{52})}} \\
 K(k_{15}) &= \sqrt{\frac{(\sqrt{5} + 1)\Gamma(\frac{1}{15})\Gamma(\frac{2}{15})\Gamma(\frac{4}{15})\Gamma(\frac{16}{15})}{240\pi}} \\
 K(k_{16}) &= \frac{(2^{1/4} + 1)^2 \Gamma^2(\frac{1}{4})}{2^{9/2} \sqrt{\pi}} \\
 K(k_{17}) &= C_1 \left[ \frac{\Gamma(\frac{1}{68})\Gamma(\frac{9}{68})\Gamma(\frac{7}{68})\Gamma(\frac{11}{68})\Gamma(\frac{13}{68})}{\Gamma(\frac{5}{68})\Gamma(\frac{15}{68})\Gamma(\frac{19}{68})\Gamma(\frac{29}{68})} \right]^{1/4} \\
 &\quad \times [\Gamma(\frac{21}{68})\Gamma(\frac{25}{68})\Gamma(\frac{27}{68})\Gamma(\frac{31}{68})\Gamma(\frac{33}{68})]^{1/4} \\
 K(k_{25}) &= \frac{\sqrt{5} + 2}{20} \frac{\Gamma^2(\frac{1}{4})}{\sqrt{\pi}},
 \end{aligned}$$

where  $\Gamma(z)$  is the GAMMA FUNCTION and  $C_1$  is an algebraic number (Borwein and Borwein 1987, p. 298).

Borwein and Zucker (1992) give amazing expressions for singular values of complete elliptic integrals in terms of CENTRAL BETA FUNCTIONS

$$\beta(p) \equiv B(p, p). \quad (3)$$

Furthermore, they show that  $K(k_n)$  is *always* expressible in terms of these functions for  $n \equiv 1, 2 \pmod{4}$ . In such cases, the  $\Gamma$  functions appearing in the expression are of the form  $\Gamma(t/4n)$  where  $1 \leq t \leq (2n-1)$  and  $(t, 4n) = 1$ . The terms in the numerator depend on the sign of the KRONECKER SYMBOL  $\{t/4n\}$ . Values for the first few  $n$  are

$$\begin{aligned}
 K(k_1) &= 2^{-2} \beta(\tfrac{1}{4}) \\
 K(k_2) &= 2^{-13/4} \beta(\tfrac{1}{8}) \\
 K(k_3) &= 2^{-4/3} 3^{-1/4} \beta(\tfrac{1}{3}) = 2^{-5/3} 3^{-3/4} \beta(\tfrac{1}{6}) \\
 K(k_5) &= 2^{-33/20} 5^{-5/8} (11 + 5\sqrt{5})^{1/4} \sin(\tfrac{1}{20}\pi) \beta(\tfrac{1}{2}) \\
 &= 2^{-29/20} 5^{-3/8} (1 + \sqrt{5})^{1/4} \sin(\tfrac{3}{20}\pi) \beta(\tfrac{3}{20}) \\
 K(k_6) &= 2^{-47/12} 3^{-3/4} (\sqrt{2} - 1)(\sqrt{3} + 1) \beta(\tfrac{1}{24}) \\
 &= 2^{-43/12} 3^{-1/4} (\sqrt{3} - 1) \beta(\tfrac{5}{24}) \\
 K(k_7) &= 2 \cdot 7^{-3/4} \sin(\tfrac{1}{7}\pi) \sin(\tfrac{2}{7}\pi) B(\tfrac{1}{7}, \tfrac{2}{7}) \\
 &= 2^{-2/7} 7^{-1/4} \frac{\beta(\frac{1}{7})\beta(\frac{2}{7})}{\beta(\frac{1}{14})}
 \end{aligned}$$

$$\begin{aligned}
 K(k_{10}) &= 2^{-61/20} 5^{-1/4} (\sqrt{5} - 2)^{1/2} (\sqrt{10} + 3) \frac{\beta(\frac{1}{8})\beta(\frac{7}{40})}{\beta(\frac{1}{40})} \\
 &= 2^{-15/4} 5^{-3/4} (\sqrt{5} - 2)^{1/2} \frac{\beta(\frac{1}{40})\beta(\frac{1}{9}40)}{\beta(\frac{3}{8})} \\
 K(k_{11}) &= R \cdot 2^{-7/11} \sin(\tfrac{1}{11}\pi) \sin(\tfrac{3}{11}\pi) B(\tfrac{1}{22}, \tfrac{3}{22}) \\
 K(k_{13}) &= 2^{-3} 13^{-5/8} (5\sqrt{13} + 18)^{1/4} \\
 &\quad \times [\tan(\tfrac{1}{52}\pi) \tan(\tfrac{3}{52}\pi) \tan(\tfrac{9}{52}\pi)]^{1/2} \frac{\beta(\frac{1}{52})\beta(\frac{9}{52})}{\beta(\frac{23}{52})} \\
 K(k_{14}) &= \sqrt{\sqrt{4\sqrt{2} + 2} + \sqrt{2} + \sqrt{2\sqrt{2} - 1}} \cdot 2^{-13/4} 7^{-3/8} \\
 &\quad \times \left[ \frac{\tan(\frac{5}{56}\pi) \tan(\frac{13}{56}\pi)}{\tan(\frac{11}{56}\pi)} \right]^{1/4} \sqrt{\frac{\beta(\frac{5}{56})\beta(\frac{13}{56})\beta(\frac{1}{8})}{\beta(\frac{11}{56})}} \\
 K(k_{15}) &= 2^{-1} 3^{-3/4} 5^{-7/12} B(\tfrac{1}{15}, \tfrac{4}{15}) \\
 &= \frac{2^{-2} 3^{-3/4} 5^{-3/4} (\sqrt{5} - 1) \beta(\frac{1}{15}) \beta(\frac{4}{15})}{\beta(\frac{1}{3})} \\
 K(k_{17}) &= C_2 \left[ \frac{\beta(\frac{1}{68})\beta(\frac{3}{68})\beta(\frac{7}{68})\beta(\frac{9}{68})\beta(\frac{11}{68})\beta(\frac{13}{68})}{\beta(\frac{5}{68})\beta(\frac{15}{68})} \right]^{1/4},
 \end{aligned}$$

where  $R$  is the REAL ROOT of

$$x^3 - 4x = 4 = 0 \quad (4)$$

and  $C_2$  is an algebraic number (Borwein and Zucker 1992). Note that  $K(k_{11})$  is the only value in the above list which cannot be expressed in terms of CENTRAL BETA FUNCTIONS.

Using the ELLIPTIC ALPHA FUNCTION, the ELLIPTIC INTEGRALS OF THE SECOND KIND can also be found from

$$E = \frac{\pi}{4\sqrt{r}K} + \left[ 1 - \frac{\alpha(r)}{\sqrt{r}} \right] K \quad (5)$$

$$E' = \frac{\pi}{4K} + \alpha(r)K, \quad (6)$$

and by definition,

$$K' = K\sqrt{n}. \quad (7)$$

### Elliptic Integral Singular Value— $k_1$

The first SINGULAR VALUE  $k_1$ , corresponding to

$$K'(k_1) = K(k_1), \quad (1)$$

is given by

$$k_1 = \frac{1}{\sqrt{2}} \quad (2)$$

$$k'_1 = \frac{1}{\sqrt{2}}. \quad (3)$$

As shown in LEMNISCATE FUNCTION,

$$\begin{aligned} K\left(\frac{1}{\sqrt{2}}\right) &\equiv \int_0^1 \frac{dt}{\sqrt{(1-t^2)(1-\frac{1}{2}t^2)}} \\ &= \sqrt{2} \int_0^1 \frac{dt}{\sqrt{1-t^4}}. \end{aligned} \quad (4)$$

Let

$$u \equiv t^4 \quad (5)$$

$$du = 4t^3 dt = 4u^{3/4} dt \quad (6)$$

$$dt = \frac{1}{4}u^{-3/4} du, \quad (7)$$

then

$$\begin{aligned} K\left(\frac{1}{\sqrt{2}}\right) &= \frac{\sqrt{2}}{4} \int_0^1 u^{-3/4}(1-u)^{-1/2} du \\ &= \frac{\sqrt{2}}{4} B\left(\frac{1}{4}, \frac{1}{2}\right) = \frac{\Gamma(\frac{1}{4})\Gamma(\frac{1}{2})}{\Gamma(\frac{3}{4})} \frac{\sqrt{2}}{4}, \end{aligned} \quad (8)$$

where  $B(a, b)$  is the BETA FUNCTION and  $\Gamma(z)$  is the GAMMA FUNCTION. Now use

$$\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi} \quad (9)$$

and

$$\frac{1}{\Gamma(1-x)} = \frac{\sin(\pi x)}{\pi} \Gamma(x), \quad (10)$$

so

$$\frac{1}{\Gamma\left(\frac{3}{4}\right)} = \frac{1}{\Gamma\left(1-\frac{1}{4}\right)} = \frac{\sin\left(\frac{\pi}{4}\right)}{\pi} \Gamma\left(\frac{1}{4}\right) = \frac{1}{\pi\sqrt{2}} \Gamma\left(\frac{1}{4}\right). \quad (11)$$

Therefore,

$$K\left(\frac{1}{\sqrt{2}}\right) = \frac{\Gamma^2\left(\frac{1}{4}\right)\sqrt{\pi}\sqrt{2}}{4\pi\sqrt{2}} = \frac{\Gamma^2\left(\frac{1}{4}\right)}{4\sqrt{\pi}}. \quad (12)$$

Now consider

$$E\left(\frac{1}{\sqrt{2}}\right) \equiv \int_0^1 \sqrt{\frac{1-\frac{1}{2}t^2}{1-t^2}} dt. \quad (13)$$

Let

$$t^2 \equiv 1 - u^2 \quad (14)$$

$$2t dt = -2u du \quad (15)$$

$$dt = -\frac{1}{t}u du = u(1-u^2)^{-1/2} du, \quad (16)$$

so

$$\begin{aligned} E\left(\frac{1}{\sqrt{2}}\right) &= \int_0^1 \sqrt{\frac{1-\frac{1}{2}(1-u^2)}{1-(1-u^2)}} u(1-u^2)^{-1/2} du \\ &= \int_0^1 \frac{\sqrt{\frac{1}{2}(1+u^2)}}{u} u(1-u^2)^{-1/2} du \\ &= \frac{1}{\sqrt{2}} \int_0^1 \sqrt{\frac{1+u^2}{1-u^2}} du. \end{aligned} \quad (17)$$

Now note that

$$\begin{aligned} \left(\frac{1}{\sqrt{1-u^4}} + \frac{u^2}{\sqrt{1-u^4}}\right)^2 &= \frac{(1+u^2)^2}{1-u^4} \\ &= \frac{(1+u^2)^2}{(1+u^2)(1-u^2)} = \frac{1+u^2}{1-u^2}, \end{aligned} \quad (18)$$

so

$$\begin{aligned} E\left(\frac{1}{\sqrt{2}}\right) &= \frac{1}{\sqrt{2}} \int_0^1 \sqrt{\frac{1+u^2}{1-u^2}} du \\ &= \frac{1}{\sqrt{2}} \int_0^1 \left(\frac{1}{\sqrt{1-u^4}} + \frac{u^2}{\sqrt{1-u^4}}\right) du \\ &= \frac{1}{2} K\left(\frac{1}{\sqrt{2}}\right) + \frac{1}{\sqrt{2}} \int_0^1 \frac{u^2 du}{\sqrt{1-u^4}}. \end{aligned} \quad (19)$$

Now let

$$t \equiv u^4 \quad (20)$$

$$dt = 4u^3 du, \quad (21)$$

so

$$\begin{aligned}\int_0^1 \frac{u^2 du}{\sqrt{1-u^4}} &= \frac{1}{4} \int_0^1 t^{1/2} t^{-3/4} (1-t)^{-1/2} dt \\ &= \frac{1}{4} \int_0^1 t^{-1/4} (1-t)^{-1/2} dt \\ &= \frac{1}{4} B\left(\frac{3}{4}, \frac{1}{2}\right) = \frac{\Gamma(\frac{3}{4})\Gamma(\frac{1}{2})}{4\Gamma(\frac{5}{4})}.\end{aligned}\quad (22)$$

But

$$[\Gamma(\frac{5}{4})]^{-1} = [\frac{1}{4}\Gamma(\frac{1}{4})]^{-1} \quad (23)$$

$$\Gamma(\frac{3}{4}) = \pi\sqrt{2} [\Gamma(\frac{1}{4})]^{-1} \quad (24)$$

$$\Gamma(\frac{1}{2}) = \sqrt{\pi}, \quad (25)$$

so

$$\int_0^1 \frac{u^2 du}{\sqrt{1-u^4}} = \frac{1}{4} \frac{\pi\sqrt{2} \cdot 4\sqrt{\pi}}{\Gamma^2(\frac{1}{4})} = \frac{\sqrt{2}\pi^{3/2}}{\Gamma^2(\frac{1}{4})} \quad (26)$$

$$\begin{aligned}E\left(\frac{1}{\sqrt{2}}\right) &= \frac{1}{2}K + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})} = \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})} \\ &= \frac{1}{4}\sqrt{\frac{\pi}{2}} \left[ \frac{\Gamma(\frac{1}{4})}{\Gamma(\frac{3}{4})} + \frac{\Gamma(\frac{3}{4})}{\Gamma(\frac{5}{4})} \right].\end{aligned}\quad (27)$$

Summarizing (12) and (27) gives

$$\begin{aligned}K\left(\frac{1}{\sqrt{2}}\right) &= \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}} \\ K'\left(\frac{1}{\sqrt{2}}\right) &= \frac{\Gamma^2(\frac{1}{4})}{4\sqrt{\pi}} \\ E\left(\frac{1}{\sqrt{2}}\right) &= \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})} \\ E'\left(\frac{1}{\sqrt{2}}\right) &= \frac{\Gamma^2(\frac{1}{4})}{8\sqrt{\pi}} + \frac{\pi^{3/2}}{\Gamma^2(\frac{1}{4})}.\end{aligned}$$

### Elliptic Integral Singular Value— $k_2$

The second SINGULAR VALUE  $k_2$ , corresponding to

$$K'(k_2) = \sqrt{2} K(k_2), \quad (1)$$

is given by

$$k_2 = \tan\left(\frac{\pi}{8}\right) = \sqrt{2} - 1, \quad (2)$$

$$k'_2 = \sqrt{2}(\sqrt{2} - 1). \quad (3)$$

For this modulus,

$$E(\sqrt{2} - 1) = \frac{1}{4}\sqrt{\frac{\pi}{4}} \left[ \frac{\Gamma(\frac{1}{8})}{\Gamma(\frac{5}{8})} + \frac{\Gamma(\frac{5}{8})}{\Gamma(\frac{9}{8})} \right]. \quad (4)$$

### Elliptic Integral Singular Value— $k_3$

The third SINGULAR VALUE  $k_3$ , corresponding to

$$K'(k_3) = \sqrt{3} K(k_3), \quad (1)$$

is given by

$$k_3 = \sin\left(\frac{\pi}{12}\right) = \frac{1}{4}(\sqrt{6} - \sqrt{2}). \quad (2)$$

As shown by Legendre,

$$K(k_3) = \frac{\sqrt{\pi}}{2 \cdot 3^{3/4}} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \quad (3)$$

(Whittaker and Watson 1990, p. 525). In addition,

$$\begin{aligned}E(k_3) &= \frac{\pi}{4\sqrt{3}} \frac{1}{K} + \frac{\sqrt{3}+1}{2\sqrt{3}} K \\ &= \frac{1}{4} \left( \frac{\pi}{\sqrt{3}} \right)^{1/2} \left[ \left( 1 + \frac{1}{\sqrt{3}} \right) \frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{5}{6})} + \frac{2\Gamma(\frac{5}{6})}{\Gamma(\frac{1}{3})} \right],\end{aligned}\quad (4)$$

and

$$E'(k_3) = \frac{\pi\sqrt{3}}{4} \frac{1}{K'(k_3)} + \frac{\sqrt{3}-1}{2\sqrt{3}} K'(k_3). \quad (5)$$

Summarizing,

$$K[\frac{1}{4}(\sqrt{6} - \sqrt{2})] = \frac{\sqrt{\pi}}{2 \cdot 3^{3/4}} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \quad (6)$$

$$K'[\frac{1}{4}(\sqrt{6} - \sqrt{2})] = \sqrt{3}K = \frac{\sqrt{\pi}}{2 \cdot 3^{1/4}} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \quad (7)$$

$$\begin{aligned}E[\frac{1}{4}(\sqrt{6} - \sqrt{2})] &= \frac{1}{4} \left( \frac{\pi}{\sqrt{3}} \right)^{1/2} \left[ \left( 1 + \frac{1}{\sqrt{3}} \right) \frac{\Gamma(\frac{1}{3})}{\Gamma(\frac{5}{6})} + \frac{2\Gamma(\frac{5}{6})}{\Gamma(\frac{1}{3})} \right] \\ E'[\frac{1}{4}(\sqrt{6} - \sqrt{2})] &= \frac{\sqrt{\pi}}{2} \left[ 3^{3/4} \frac{\Gamma(\frac{2}{3})}{\Gamma(\frac{1}{6})} + \frac{\sqrt{3}-1}{2 \cdot 3^{3/4}} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \right].\end{aligned}\quad (8)$$

$$\begin{aligned}E'[\frac{1}{4}(\sqrt{6} - \sqrt{2})] &= \frac{\sqrt{\pi}}{2} \left[ 3^{3/4} \frac{\Gamma(\frac{2}{3})}{\Gamma(\frac{1}{6})} + \frac{\sqrt{3}-1}{2 \cdot 3^{3/4}} \frac{\Gamma(\frac{1}{6})}{\Gamma(\frac{2}{3})} \right].\end{aligned}\quad (9)$$

(Whittaker and Watson 1990).

**Elliptic Lambda Function**

The  $\lambda$  GROUP is the SUBGROUP of the GAMMA GROUP with  $a$  and  $d$  ODD;  $b$  and  $c$  EVEN. The function

$$\lambda(t) \equiv \lambda(q) \equiv k^2(q) = \left[ \frac{\vartheta_2(q)}{\vartheta_3(q)} \right]^4, \quad (1)$$

where

$$q \equiv e^{i\pi t} \quad (2)$$

is a  $\lambda$ -MODULAR FUNCTION and  $\vartheta_i$  are THETA FUNCTIONS.

$\lambda^*(r)$  gives the value of the MODULUS  $k_r$  for which the complementary and normal complete ELLIPTIC INTEGRALS OF THE FIRST KIND are related by

$$\frac{K'(k_r)}{K(k_r)} = \sqrt{r}. \quad (3)$$

It can be computed from

$$\lambda^*(r) \equiv k(q) = \frac{\vartheta_2^2(q)}{\vartheta_3^2(q)}, \quad (4)$$

where

$$q \equiv e^{-\pi\sqrt{r}}, \quad (5)$$

and  $\vartheta_i$  is a THETA FUNCTION.

From the definition of the lambda function,

$$\lambda^*(r') = \lambda^*\left(\frac{1}{r}\right) = \lambda^{*'}(r). \quad (6)$$

For all rational  $r$ ,  $K(\lambda^*(r))$  and  $E(\lambda^*(r))$  are expressible in terms of a finite number of GAMMA FUNCTIONS (Selberg and Chowla 1967).  $\lambda^*(r)$  is related to the RAMANUJAN  $g$ - AND  $G$ -FUNCTIONS by

$$\lambda^*(n) = \frac{1}{2}(\sqrt{1 + G_n^{-12}} - \sqrt{1 - G_n^{-12}}) \quad (7)$$

$$\lambda^*(n) = g_n^6(\sqrt{g_n^{12} + g_n^{-12}} - g_n^6). \quad (8)$$

Special values are

$$\lambda^*\left(\frac{2}{29}\right) = (13\sqrt{58} - 99)(\sqrt{2} + 1)^6$$

$$\lambda^*\left(\frac{2}{5}\right) = (\sqrt{10} - 3)(\sqrt{2} + 1)^2$$

$$\lambda^*\left(\frac{2}{3}\right) = (2 - \sqrt{3})(\sqrt{2} + \sqrt{3})$$

$$\lambda^*\left(\frac{3}{4}\right) = (\sqrt{3} - \sqrt{2})^2(\sqrt{2} + 1)^2$$

$$\lambda^*(1) = \frac{1}{\sqrt{2}}$$

$$\lambda^*(2) = \sqrt{2} - 1$$

$$\lambda^*(3) = \frac{1}{4}\sqrt{2}(\sqrt{3} - 1)$$

$$\lambda^*(4) = 3 - 2\sqrt{2}$$

$$\lambda^*(5) = \frac{1}{2}(\sqrt{\sqrt{5} - 1} - \sqrt{3 - \sqrt{5}})$$

$$\lambda^*(6) = (2 - \sqrt{3})(\sqrt{3} - \sqrt{2})$$

$$\lambda^*(7) = \frac{1}{8}\sqrt{2}(3 - \sqrt{7})$$

$$\lambda^*(8) = (\sqrt{2} + 1 - \sqrt{2\sqrt{2} + 2})^2$$

$$\lambda^*(9) = \frac{1}{2}(\sqrt{2} - 3^{1/4})(\sqrt{3} - 1)$$

$$\lambda^*(10) = (\sqrt{10} - 3)(\sqrt{2} - 1)^2$$

$$\lambda^*(11) = \frac{1}{12}\sqrt{6}\left(\sqrt{1 + 2x_{11} - 4x_{11}^{-1}} - \sqrt{11 + 2x_{11} - 4x_{11}^{-1}}\right)$$

$$\lambda^*(12) = (\sqrt{3} - \sqrt{2})^2(\sqrt{2} - 1)^2 = 15 - 10\sqrt{2} + 8\sqrt{3} - 6\sqrt{6}$$

$$\lambda^*(13) = \frac{1}{2}(\sqrt{5\sqrt{13} - 17} - \sqrt{19 - 5\sqrt{13}})$$

$$\lambda^*(14) = -11 - 8\sqrt{2} - 2(\sqrt{2} + 2)\sqrt{5 + 4\sqrt{2}} + \sqrt{11 + 8\sqrt{2}}(2 + 2\sqrt{2} + \sqrt{2}\sqrt{5 + 4\sqrt{2}})$$

$$\lambda^*(15) = \frac{1}{16}\sqrt{2}(3 - \sqrt{5})(\sqrt{5} - \sqrt{3})(2 - \sqrt{3})$$

$$\lambda^*(16) = \frac{(2^{1/4} - 1)^2}{(2^{1/4} + 1)^2}$$

$$\lambda^*(17) = \frac{1}{4}\sqrt{2}(\sqrt{42 + 10\sqrt{17}} - 13\sqrt{-3 + \sqrt{17}}\sqrt{5 + \sqrt{17}} - 3\sqrt{17}\sqrt{-3 + \sqrt{17}}\sqrt{5 + \sqrt{17}} - \sqrt{-38 - 10\sqrt{17} + 13\sqrt{-3 + \sqrt{17}}}\sqrt{5 + \sqrt{17}} + 3\sqrt{17}\sqrt{-3 + \sqrt{17}}\sqrt{5 + \sqrt{17}})$$

$$\lambda^*(18) = (\sqrt{2} - 1)^3(2 - \sqrt{3})^2$$

$$\lambda^*(22) = (3\sqrt{11} - 7\sqrt{2})(10 - 3\sqrt{11})$$

$$\lambda^*(30) = (\sqrt{3} - \sqrt{2})^2(2 - \sqrt{3})(\sqrt{6} - \sqrt{5})(4 - \sqrt{15})$$

$$\lambda^*(34) = (\sqrt{2} - 1)^2(3\sqrt{2} - \sqrt{17}) \times (\sqrt{297 + 72\sqrt{17}} - \sqrt{296 + 72\sqrt{17}})$$

$$\lambda^*(42) = (\sqrt{2} - 1)^2(2 - \sqrt{3})^2(\sqrt{7} - \sqrt{6})(8 - 3\sqrt{7})$$

$$\lambda^*(58) = (13\sqrt{58} - 99)(\sqrt{2} - 1)^6$$

$$\lambda^*(210) = (\sqrt{2} - 1)^2(2 - \sqrt{3})(\sqrt{7} - \sqrt{6})^2(8 - 3\sqrt{7}) \times (\sqrt{10} - 3)^2(4 - \sqrt{15})^2(\sqrt{15} - \sqrt{14})(6 - \sqrt{35}),$$

where

$$x_{11} \equiv (17 + 3\sqrt{33})^{1/3}.$$

In addition,

$$\lambda^*(1') = \frac{1}{\sqrt{2}}$$

$$\lambda^*(2') = \sqrt{2\sqrt{2} - 2}$$

$$\lambda^*(3') = \frac{1}{4}\sqrt{2}(\sqrt{3} + 1)$$

$$\lambda^*(4') = 2^{1/4}(2\sqrt{2} - 2)$$

$$\lambda^*(5') = \frac{1}{2}\left(\sqrt{\sqrt{5} - 1} + \sqrt{3 - \sqrt{5}}\right)$$

$$\lambda^*(7') = \frac{1}{8}\sqrt{2}(3 + \sqrt{7})$$

$$\lambda^*(9') = \frac{1}{2}(\sqrt{2} + 3^{1/4})(\sqrt{3} - 1)$$

$$\lambda^*(12') = 2\sqrt{-208 + 147\sqrt{2} - 120\sqrt{3} + 85\sqrt{6}}.$$

## Elliptic Logarithm

A generalization of integrals of the form

$$\int_{\infty}^x \frac{dt}{\sqrt{t^2 + at}},$$

which can be expressed in terms of logarithmic and inverse trigonometric functions to

$$\operatorname{eln}(x) \equiv \int_x^{\infty} \frac{dt}{\sqrt{t^3 + at^2 + bt}}.$$

The inverse of the elliptic logarithm is the ELLIPTIC EXPONENTIAL FUNCTION.

## Elliptic Modular Function

$$\varphi(z) = \left[ \frac{\vartheta_2^4(0, z)}{\vartheta_3^4(0, z)} \right]^{1/8},$$

where  $\vartheta$  is a THETA FUNCTION. A special case is

$$\varphi(-e^{-\pi\sqrt{3}}) = (4\sqrt{3} - 7)^{1/8}.$$

see also MODULAR FUNCTION

## Elliptic Paraboloid

A QUADRATIC SURFACE which has ELLIPTICAL CROSS-SECTION. The elliptic paraboloid of height  $h$ , SEMIMAJOR AXIS  $a$ , and SEMIMINOR AXIS  $b$  can be specified parametrically by

$$\begin{aligned} x &= a\sqrt{u} \cos v \\ y &= b\sqrt{u} \sin v \\ z &= u. \end{aligned}$$

for  $v \in [0, 2\pi)$  and  $u \in [0, h]$ .

see also ELLIPTIC CONE, ELLIPTIC CYLINDER, PARABOLOID

### References

## Elliptic Partial Differential Equation

A second-order PARTIAL DIFFERENTIAL EQUATION, i.e., one of the form

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + F = 0, \quad (1)$$

is called elliptic if the MATRIX

$$Z \equiv \begin{bmatrix} A & B \\ B & C \end{bmatrix} \quad (2)$$

is POSITIVE DEFINITE. LAPLACE'S EQUATION and POISSON'S EQUATION are examples of elliptic partial differential equations. For an elliptic partial differential equation, BOUNDARY CONDITIONS are used to give the constraint  $u(x, y) = g(x, y)$  on  $\partial\Omega$ , where

$$u_{xx} + u_{yy} = f(u_x, u_y, u, x, y) \quad (3)$$

holds in  $\Omega$ .

see also HYPERBOLIC PARTIAL DIFFERENTIAL EQUATION, PARABOLIC PARTIAL DIFFERENTIAL EQUATION, PARTIAL DIFFERENTIAL EQUATION

## Elliptic Plane

The REAL PROJECTIVE PLANE with elliptic METRIC where the distance between two points  $P$  and  $Q$  is defined as the RADIAN ANGLE between the projection of the points on the surface of a SPHERE (which is tangent to the plane at a point  $S$ ) from the ANTIPODE  $N$  of the tangent point.

### References

**Elliptic Point**

A point  $\mathbf{p}$  on a REGULAR SURFACE  $M \in \mathbb{R}^3$  is said to be elliptic if the GAUSSIAN CURVATURE  $K(\mathbf{p}) > 0$  or equivalently, the PRINCIPAL CURVATURES  $\kappa_1$  and  $\kappa_2$  have the same sign.

**Elliptical Projection**

see MOLLWEIDE PROJECTION

**Elliptic Pseudoprime**

Let  $E$  be an ELLIPTIC CURVE defined over the FIELD of RATIONAL NUMBERS  $\mathbb{Q}(\sqrt{-d})$  having equation

$$y^2 = x^3 + ax + b$$

with  $a$  and  $b$  INTEGERS. Let  $P$  be a point on  $E$  with integer coordinates and having infinite order in the additive group of rational points of  $E$ , and let  $n$  be a COMPOSITE NATURAL NUMBER such that  $(-d/n) = -1$ , where  $(-d/n)$  is the JACOBI SYMBOL. Then if

$$(n+1)P \equiv 0 \pmod{n},$$

$n$  is called an elliptic pseudoprime for  $(E, P)$ .

**Elliptic Rotation**

Leaves the CIRCLE

$$x^2 + y^2 = 1$$

invariant.

$$\begin{aligned} x' &= x \cos \theta - y \sin \theta \\ y' &= x \sin \theta + y \cos \theta. \end{aligned}$$

see also EQUIAFFINITY

**Elliptic Theta Function**

see NEVILLE THETA FUNCTION, THETA FUNCTION

**Elliptic Torus**

A generalization of the ring TORUS produced by stretching or compressing in the  $z$  direction. It is given by the parametric equations

$$\begin{aligned} x(u, v) &= (a + b \cos v) \cos u \\ y(u, v) &= (a + b \cos v) \sin u \\ z(u, v) &= c \sin v. \end{aligned}$$

**Elsasser Function**

$$E(y, u) \equiv \int_{-1/2}^{1/2} \exp \left[ -\frac{2\pi y u \sinh(2\pi y)}{\cosh(2\pi y) - \cos(2\pi x)} \right] dx.$$

**Embeddable Knot**

A KNOT  $K$  is an  $n$ -embeddable knot if it can be placed on a GENUS  $n$  standard embedded surface without crossings, but  $K$  cannot be placed on any standardly embedded surface of lower GENUS without crossings. Any KNOT is an  $n$ -embeddable knot for some  $n$ . The FIGURE-OF-EIGHT KNOT is a 2-EMBEDDABLE KNOT. A knot with BRIDGE NUMBER  $b$  is an  $n$ -embeddable knot where  $n \leq b$ .

see also TUNNEL NUMBER

**Embedding**

see EXTRINSIC CURVATURE, HYPERBOLOID EMBEDDING, INJECTION, SPHERE EMBEDDING

**Empty Set**

The SET containing no elements, denoted  $\emptyset$ . Strangely, the empty set is both OPEN and CLOSED for any SET  $X$  and TOPOLOGY. A GROUPOID, SEMIGROUP, QUASIGROUP, RINGOID, and SEMIRING can be empty. A MONOID, GROUP, and RINGS must have at least one element, while DIVISION RINGS and FIELDS must have at least two elements.

**References**

- Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, p. 266, 1996.

**Enantiomer**

Two objects which are MIRROR IMAGES of each other are called enantiomers. The term enantiomer is synonymous with ENANTIOMORPH.

see also AMPHICHIRAL KNOT, CHIRAL, DISYMMETRIC, HANDEDNESS, MIRROR IMAGE, REFLEXIBLE

**References**

- Ball, W. W. R. and Coxeter, H. S. M. "Polyhedra." Ch. 5 in *Mathematical Recreations and Essays*, 13th ed. New York: Dover, pp. 130–161, 1987.

**Enantiomorph**

see ENANTIOMER

**Encoding**

An encoding is a way of representing a number or expression in terms of another (usually simpler) one. However, multiple expressions can also be encoded as a single expression, as in, for example,

$$(a, b) \equiv \frac{1}{2}[(a + b)^2 + 3a + b]$$

which encodes  $a$  and  $b$  uniquely as a single number.

$a$	$b$	$(a, b)$
0	0	0
0	1	1
1	0	2
0	2	3
1	2	4
2	0	5

see also CODE, CODING THEORY

### Endogenous Variable

An economic variable which is independent of the relationships determining the equilibrium levels, but nonetheless affects the equilibrium.

see also EXOGENOUS VARIABLE

### Endomorphism

A SURJECTIVE MORPHISM from an object to itself. In ERGODIC THEORY, let  $X$  be a SET,  $F$  a SIGMA ALGEBRA on  $X$  and  $m$  a PROBABILITY MEASURE. A MAP  $T : X \rightarrow X$  is called an endomorphism or MEASURE-PRESERVING TRANSFORMATION if

1.  $T$  is SURJECTIVE,
2.  $T$  is MEASURABLE,
3.  $m(T^{-1}A) = m(A)$  for all  $A \in F$ .

An endomorphism is called ERGODIC if it is true that  $T^{-1}A = A$  IMPLIES  $m(A) = 0$  or 1, where  $T^{-1}A = \{x \in X : T(x) \in A\}$ .

see also MEASURABLE FUNCTION, MEASURE-PRESERVING TRANSFORMATION, MORPHISM, SIGMA ALGEBRA, SURJECTIVE

### Endraß Octic

Endraß surfaces are a pair of OCTIC SURFACES which have 168 ORDINARY DOUBLE POINTS. This is the maximum number known to exist for an OCTIC SURFACE, although the rigorous upper bound is 174. The equations of the surfaces  $X_8^\pm$  are

$$64(x^2 - w^2)(y^2 - w^2)[(x + y)^2 - 2w^2] \\ [(x - y)^2 - 2w^2] - \{-4(1 \pm \sqrt{2})(x^2 + y^2)^2 \\ + [8(2 \pm \sqrt{2})z^2 + 2(2 \pm 7\sqrt{2})w^2](x^2 + y^2) \\ - 16z^4 + 8(1 \mp 2\sqrt{2})z^2w^2 - (1 + 12\sqrt{2})w^4\}^2 = 0,$$

where  $w$  is a parameter taken as  $w = 1$  in the above plots. All ORDINARY DOUBLE POINTS of  $X_8^+$  are real, while 24 of those in  $X_8^-$  are complex. The surfaces were discovered in a 5-D family of octics with 112 nodes, and are invariant under the GROUP  $D_8 \otimes Z_2$ .

### Energy

The term energy has an important physical meaning in physics and is an extremely useful concept. A much more abstract mathematical generalization is defined as follows. Let  $\Omega$  be a SPACE with MEASURE  $\mu \geq 0$  and let  $\Phi(P, Q)$  be a real function on the PRODUCT SPACE  $\Omega \times \Omega$ . When

$$(\mu, \nu) = \iint \Phi(P, Q) d\mu(Q) d\nu(P) \\ = \int \Phi(P, \mu) d\nu(P)$$

exists for measures  $\mu, \nu \geq 0$ ,  $(\mu, \nu)$  is called the MUTUAL ENERGY and  $(\mu, \mu)$  is called the ENERGY.

**Enneagonal Number**

see NONAGONAL NUMBER

**Enneakaidecagon**

see ENNEADECAGON

**Enneper's Surfaces**

The Enneper surfaces are a three-parameter family of surfaces with constant curvature. In general, they are described by elliptic functions. However, special cases which can be specified parametrically using ELEMENTARY FUNCTION include the KUEN SURFACE, REMBS' SURFACES, and SIEVERT'S SURFACE. The surfaces shown above can be generated using the ENNEPER-WEIERSTRAß PARAMETERIZATION with

$$f(\zeta) = 1 \quad (1)$$

$$g(\zeta) = \zeta. \quad (2)$$

Letting  $z = re^{i\phi}$  and taking the REAL PART give

$$x = \Re[re^{i\phi} - \frac{1}{3}r^3e^{3i\phi}] \quad (3)$$

$$y = \Re[ire^{i\phi} + \frac{1}{3}ir^3e^{3i\phi}] \quad (4)$$

$$z = \Re[r^2e^{2i\phi}], \quad (5)$$

where  $r \in [0, 1]$  and  $\phi \in [-\pi, \pi]$ . Letting  $z = u + iv$  instead gives the figure on the right,

$$x = u - \frac{1}{3}u^3 + uv^2 \quad (6)$$

$$y = -v - u^2v + \frac{1}{3}v^3 \quad (7)$$

$$z = u^2 - v^2 \quad (8)$$

(do Carmo 1986, Gray 1993, Nordstrand). This surface has a HOLE in its middle. Nordstrand gives the implicit form

$$\left(\frac{y^2 - x^2}{2z} + \frac{2}{9}z^2 + \frac{2}{3}\right)^3 - 6\left[\frac{(y^2 - x^2)}{4z} - \frac{1}{4}(x^2 + y^2 + \frac{8}{9}z^2) + \frac{2}{9}\right]^2 = 0. \quad (9)$$

**Enormous Theorem**

see CLASSIFICATION THEOREM

**Enriques Surfaces**

An Enriques surface  $X$  is a smooth compact complex surface having irregularity  $q(X) = 0$  and nontrivial canonical sheaf  $K_X$  such that  $K_X^2 = \mathcal{O}_X$  (Endraß). Such surfaces cannot be embedded in projective 3-space, but there nonetheless exist transformations onto singular surfaces in projective 3-space. There exists a family of such transformed surfaces of degree six which passes through each edge of a TETRAHEDRON twice. A subfamily with tetrahedral symmetry is given by the two-parameter  $(r, c)$  family of surfaces

$$f_r x_0 x_1 x_2 x_3 + c(x_0^2 x_1^2 x_2^2 + x_0^2 x_1^2 x_3^2 + x_0^2 x_2^2 x_3^2 + x_1^2 x_2^2 x_3^2) = 0$$

and the polynomial  $f_r$  is a sphere with radius  $r$ ,

$$f_r = (3 - r)(x_0^2 + x_1^2 + x_2^2 + x_3^2) - 2(1 + r)(x_0 x_1 + x_0 x_2 + x_0 x_3 + x_1 x_2 + x_1 x_3 + x_2 x_3)$$

(Endraß).

#### Entire Function

If a function is ANALYTIC on  $\mathbb{C}^*$ , where  $\mathbb{C}^*$  denotes the extended COMPLEX PLANE, then it is said to be entire. *see also* ANALYTIC FUNCTION, HOLOMORPHIC FUNCTION, MEROMORPHIC

#### Entringer Number

The Entringer numbers  $E(n, k)$  are the number of PERMUTATIONS of  $\{1, 2, \dots, n+1\}$ , starting with  $k+1$ , which, after initially falling, alternately fall then rise. The Entringer numbers are given by

$$\begin{aligned} E(0, 0) &= 1 \\ E(n, 0) &= 0 \end{aligned}$$

together with the RECURRENCE RELATION

$$E(n, k) = E(n, k+1) + E(n-1, n-k).$$

The numbers  $E(n) = E(n, n)$  are the SECANT and TANGENT NUMBERS given by the MACLAURIN SERIES

$\sec x + \tan x$

$$= A_0 + A_1x + A_2\frac{x^2}{2!} + A_3\frac{x^3}{3!} + A_4\frac{x^4}{4!} + A_5\frac{x^5}{5!} + \dots$$

#### Entropy

In physics, the word entropy has important physical implications as the amount of "disorder" of a system. In mathematics, a more abstract definition is used. The (Shannon) entropy of a variable  $X$  is defined as

$$H(X) \equiv - \sum_x p(x) \ln[p(x)],$$

where  $p(x)$  is the probability that  $X$  is in the state  $x$ , and  $p \ln p$  is defined as 0 if  $p = 0$ . The joint entropy of variables  $X_1, \dots, X_n$  is then defined by

$$\begin{aligned} H(X_1, \dots, X_n) \\ = - \sum_{x_1} \dots \sum_{x_n} p(x_1, \dots, x_n) \ln[p(x_1, \dots, x_n)]. \end{aligned}$$

#### Envelope

The envelope of a one-parameter family of curves given implicitly by

$$U(x, y, c) = 0, \quad (1)$$

or in parametric form by  $(f(t, c), g(t, c))$ , is a curve which touches every member of the family. For a curve represented by  $(f(t, c), g(t, c))$ , the envelope is found by solving

$$0 = \frac{\partial f}{\partial t} \frac{\partial g}{\partial c} - \frac{\partial f}{\partial c} \frac{\partial g}{\partial t}. \quad (2)$$

For a curve represented implicitly, the envelope is given by simultaneously solving

$$\frac{\partial U}{\partial c} = 0 \quad (3)$$

$$U(x, y, c) = 0. \quad (4)$$

### Envelope Theorem

Relates EVOLUTES to single paths in the CALCULUS OF VARIATIONS. Proved in the general case by Darboux and Zermelo (1894) and Kneser (1898). It states: "When a single parameter family of external paths from a fixed point  $O$  has an ENVELOPE, the integral from the fixed point to any point  $A$  on the ENVELOPE equals the integral from the fixed point to any second point  $B$  on the ENVELOPE plus the integral along the envelope to the first point on the ENVELOPE,  $J_{OA} = J_{OB} + J_{BA}$ ."

#### References

- Kimball, W. S. *Calculus of Variations by Parallel Displacement*. London: Butterworth, p. 292, 1952.

### Envyfree

An agreement in which all parties feel as if they have received the best deal.

### Epicycloid

The path traced out by a point  $P$  on the EDGE of a CIRCLE of RADIUS  $b$  rolling on the outside of a CIRCLE of RADIUS  $a$ .

It is given by the equations

$$x = (a + b) \cos \phi - b \cos \left( \frac{a+b}{b} \phi \right) \quad (1)$$

$$y = (a + b) \sin \phi - b \sin \left( \frac{a+b}{b} \phi \right) \quad (2)$$

$$x^2 = (a + b)^2 \cos^2 \phi - 2b(a + b) \cos \phi \cos \left( \frac{a+b}{b} \phi \right) + b^2 \cos^2 \left( \frac{a+b}{b} \phi \right) \quad (3)$$

$$y^2 = (a + b)^2 \sin^2 \phi - 2b(a + b) \sin \phi \sin \left( \frac{a+b}{b} \phi \right) + b^2 \sin^2 \left( \frac{a+b}{b} \phi \right) \quad (4)$$

$$r^2 = x^2 + y^2 = (a + b)^2 + b^2 - 2b(a + b) \left\{ \cos \left[ \left( \frac{a}{b} + 1 \right) \phi \right] \cos \phi + \sin \left[ \left( \frac{a}{b} + 1 \right) \phi \right] \sin \phi \right\}. \quad (5)$$

But

$$\cos \alpha \cos \beta + \sin \alpha \sin \beta = \cos(\alpha - \beta), \quad (6)$$

so

$$r^2 = (a + b)^2 + b^2 - 2b(a + b) \cos \left[ \left( \frac{a}{b} + 1 \right) \phi - \phi \right] = (a + b)^2 + b^2 - 2b(a + b) \cos \left( \frac{a}{b} \phi \right). \quad (7)$$

Note that  $\phi$  is the parameter here, *not* the polar angle. The polar angle from the center is

$$\tan \theta = \frac{y}{x} = \frac{(a + b) \sin \phi - b \sin \left( \frac{a+b}{b} \phi \right)}{(a + b) \cos \phi - b \cos \left( \frac{a+b}{b} \phi \right)}. \quad (8)$$

To get  $n$  CUSPS in the epicycloid,  $b = a/n$ , because then  $n$  rotations of  $b$  bring the point on the edge back to its starting position.

$$\begin{aligned} r^2 &= a^2 \left[ \left( 1 + \frac{1}{n} \right)^2 + \left( \frac{1}{n} \right)^2 - 2 \left( \frac{1}{n} \right) \left( 1 + \frac{1}{n} \right) \cos(n\phi) \right] \\ &= a^2 \left[ 1 + \frac{2}{n} + \frac{1}{n^2} + \frac{1}{n^2} - \left( \frac{2}{n} \right) \left( \frac{n+1}{n} \right) \cos(n\phi) \right] \\ &= a^2 \left[ \frac{n^2 + 2n + 2}{n^2} - \frac{2(n+1)}{n^2} \cos(n\phi) \right] \\ &= \frac{a^2}{n^2} [(n^2 + 2n + 2) - 2(n+1) \cos(n\phi)], \end{aligned} \quad (9)$$

so

$$\begin{aligned} \tan \theta &= \frac{a \left( \frac{n+1}{n} \right) \sin \phi - \frac{a}{n} \sin[(n+1)\phi]}{a \left( \frac{n+1}{n} \right) \cos \phi - \frac{a}{n} \cos[(n+1)\phi]} \\ &= \frac{(n+1) \sin \phi - \sin[(n+1)\phi]}{(n+1) \cos \phi - \cos[(n+1)\phi]}. \end{aligned} \quad (10)$$

An epicycloid with one cusp is called a **CARDIOID**, one with two cusps is called a **NEPHROID**, and one with five cusps is called a **RANUNCULOID**.

$n$ -epicycloids can also be constructed by beginning with the **DIAMETER** of a **CIRCLE**, offsetting one end by a series of steps while at the same time offsetting the other end by steps  $n$  times as large. After traveling around the **CIRCLE** once, an  $n$ -cusped epicycloid is produced, as illustrated above (Madachy 1979).

Epicycloids have **TORSION**

$$\tau = 0 \quad (11)$$

and satisfy

$$\frac{s^2}{a^2} + \frac{\rho^2}{b^2} = 1, \quad (12)$$

where  $\rho$  is the **RADIUS OF CURVATURE** ( $1/\kappa$ ).

#### Epicycloid—1-Cusped

A 1-cusped epicycloid has  $b = a$ , so  $n = 1$ . The radius measured from the center of the large circle for a 1-cusped epicycloid is given by **EPICYCLOID** equation (9) with  $n = 1$  so

$$\begin{aligned} r^2 &= \frac{a^2}{n^2} [(n^2 + 2n + 2) - 2(n + 1) \cos(n\phi)] \\ &= a^2 [(1^2 + 2 \cdot 1 + 2) - 2(1 + 1) \cos(1 \cdot \phi)] \\ &= a^2 (5 - 4 \cos \phi) \end{aligned} \quad (1)$$

$$r = a \sqrt{5 - 4 \cos \phi}, \quad (2)$$

and

$$\tan \theta = \frac{2 \sin \phi - \sin(2\phi)}{2 \cos \phi - \cos(2\phi)}. \quad (3)$$

The 1-cusped epicycloid is just an offset **CARDIOID**.

#### Epicycloid—2-Cusped

see **NEPHROID**

#### Epicycloid Evolute

The **EVOLUTE** of the **EPICYCLOID**

$$\begin{aligned} x &= (a + b) \cos t - b \cos \left[ \left( \frac{a + b}{b} \right) t \right] \\ y &= (a + b) \sin t - b \sin \left[ \left( \frac{a + b}{b} \right) t \right] \end{aligned}$$

is another **EPICYCLOID** given by

$$\begin{aligned} x &= \frac{a}{a + 2b} \left\{ (a + b) \cos t + b \cos \left[ \left( \frac{a + b}{b} \right) t \right] \right\} \\ y &= \frac{a}{a + 2b} \left\{ (a + b) \sin t + b \cos \left[ \left( \frac{a + b}{b} \right) t \right] \right\}. \end{aligned}$$

#### Epicycloid Involute

The INVOLUTE of the EPICYCLOID

$$x = (a+b) \cos t - b \cos \left[ \left( \frac{a+b}{b} \right) t \right]$$

$$y = (a+b) \sin t - b \sin \left[ \left( \frac{a+b}{b} \right) t \right]$$

is another EPICYCLOID given by

$$x = \frac{a+2b}{a} \left\{ (a+b) \cos t + b \cos \left[ \left( \frac{a+b}{b} \right) t \right] \right\}$$

$$y = \frac{a+2b}{a} \left\{ (a+b) \sin t + b \sin \left[ \left( \frac{a+b}{b} \right) t \right] \right\}.$$

### Epicycloid Pedal Curve

The PEDAL CURVE of an EPICYCLOID with PEDAL POINT at the center, shown for an epicycloid with four cusps, is not a ROSE as claimed by Lawrence (1972).

#### References

Lawrence, J. D. *A Catalog of Special Plane Curves*. New York: Dover, p. 204, 1972.

### Epicycloid Radial Curve

The RADIAL CURVE of an EPICYCLOID is shown above for an epicycloid with four cusps. It is not a ROSE, as claimed by Lawrence (1972).

#### References

Lawrence, J. D. *A Catalog of Special Plane Curves*. New York: Dover, p. 202, 1972.

### Epimenides Paradox

A PARADOX, also called the LIAR'S PARADOX, attributed to the philosopher Epimenides in the sixth century BC. "All Cretans are liars... One of their own poets has said so." A sharper version of the paradox is the EUBULIDES PARADOX, "This statement is false."

Hofstadter, D. R. *Gödel, Escher, Bach: An Eternal Golden Braid*. New York: Vintage Books, p. 17, 1989.

### Epimorphism

A SURJECTIVE MORPHISM.

### Epispiral

A plane curve with polar equation

$$r = \frac{a}{\cos(n\theta)}.$$

There are  $n$  sections if  $n$  is ODD and  $2n$  if  $n$  is EVEN.

#### References

Lawrence, J. D. *A Catalog of Special Plane Curves*. New York: Dover, pp. 192–193, 1972.

### Epispiral Inverse Curve

The INVERSE CURVE of the EPISPIRAL

$$r = a \sec(nt)$$

with INVERSION CENTER at the origin and inversion radius  $k$  is the ROSE

$$r = \frac{k \cos(nt)}{a}.$$

### Epitrochoid

The ROULETTE traced by a point  $P$  attached to a CIRCLE of radius  $b$  rolling around the outside of a fixed

CIRCLE of radius  $a$ . These curves were studied by Dürer (1525), Desargues (1640), Huygens (1679), Leibniz, Newton (1686), L'Hospital (1690), Jakob Bernoulli (1690), la Hire (1694), Johann Bernoulli (1695), Daniel Bernoulli (1725), Euler (1745, 1781). An epitrochoid appears in Dürer's work *Instruction in Measurement with Compasses and Straight Edge* (1525). He called epitrochoids SPIDER LINES because the lines he used to construct the curves looked like a spider.

The parametric equations for an epitrochoid are

$$\begin{aligned}x &= m \cos t - h \cos \left( \frac{m}{b} t \right) \\y &= m \sin t - h \sin \left( \frac{m}{b} t \right),\end{aligned}$$

where  $m \equiv a + b$  and  $h$  is the distance from  $P$  to the center of the rolling CIRCLE. Special cases include the LIMAÇON with  $a = b$ , the CIRCLE with  $a = 0$ , and the EPICYCLOID with  $h = b$ .

## Equal

Two quantities are said to be equal if they are, in some well-defined sense, equivalent. Equality of quantities  $a$  and  $b$  is written  $a = b$ .

A symbol with three horizontal line segments ( $\equiv$ ) resembling the equals sign is used to denote both equality by definition (e.g.,  $A \equiv B$  means  $A$  is DEFINED to be equal to  $B$ ) and CONGRUENCE (e.g.,  $13 \equiv 12 \pmod{1}$  means 13 divided by 12 leaves a REMAINDER of 1—a fact known to all readers of analog clocks).

see also CONGRUENCE, DEFINED, DIFFERENT, EQUAL BY DEFINITION, EQUALITY, EQUIVALENT, ISOMORPHISM

## Equal by Definition

see DEFINED

## Equal Detour Point

The center of an outer SODDY CIRCLE. It has TRIANGLE CENTER FUNCTION

$$\alpha = 1 + \frac{2\Delta}{a(b+c-a)} = \sec\left(\frac{1}{2}A\right) \cos\left(\frac{1}{2}B\right) \cos\left(\frac{1}{2}C\right) + 1.$$

Given a point  $Y$  not between  $A$  and  $B$ , a detour of length

$$|AY| + |YB| - |AB|$$

is made walking from  $A$  to  $B$  via  $Y$ , the point is of equal detour if the three detours from one side to another via  $Y$  are equal. If  $ABC$  has no ANGLE  $> 2 \sin^{-1}(4/5)$ , then the point given by the above TRILINEAR COORDINATES is the unique equal detour point. Otherwise, the ISOPERIMETRIC POINT is also equal detour.

### Equilateral Hyperbola

see RECTANGULAR HYPERBOLA

### Equilateral Triangle

An equilateral triangle is a TRIANGLE with all three sides of equal length  $s$ . An equilateral triangle also has three equal  $60^\circ$  ANGLES.

An equilateral triangle can be constructed by TRISECTING all three ANGLES of any TRIANGLE (MORLEY'S THEOREM). NAPOLEON'S THEOREM states that if three equilateral triangles are drawn on the LEGS of any TRIANGLE (either all drawn inwards or outwards) and the centers of these triangles are connected, the result is another equilateral triangle.

Given the distances of a point from the three corners of an equilateral triangle,  $a$ ,  $b$ , and  $c$ , the length of a side  $s$  is given by

$$3(a^4 + b^4 + c^4 + s^4) = (a^2 + b^2 + c^2 + s^2)^2 \quad (1)$$

(Gardner 1977, pp. 56–57 and 63). There are infinitely many solutions for which  $a$ ,  $b$ , and  $c$  are INTEGERS. In these cases, one of  $a$ ,  $b$ ,  $c$ , and  $s$  is DIVISIBLE by 3, one by 5, one by 7, and one by 8 (Guy 1994, p. 183).

The ALTITUDE  $h$  of an equilateral triangle is

$$h = \frac{1}{2}\sqrt{3}s, \quad (2)$$

where  $s$  is the side length, so the AREA is

$$A = \frac{1}{2}sh = \frac{1}{4}\sqrt{3}s^2. \quad (3)$$

The INRADIUS  $r$ , CIRCUMRADIUS  $R$ , and AREA  $A$  can be computed directly from the formulas for a general regular POLYGON with side length  $s$  and  $n = 3$  sides,

$$r = \frac{1}{2}s \cot\left(\frac{\pi}{3}\right) = \frac{1}{2}s \tan\left(\frac{\pi}{6}\right) = \frac{1}{6}\sqrt{3}s \quad (4)$$

$$R = \frac{1}{2}s \csc\left(\frac{\pi}{3}\right) = \frac{1}{2}s \sec\left(\frac{\pi}{6}\right) = \frac{1}{3}\sqrt{3}s \quad (5)$$

$$A = \frac{1}{4}ns^2 \cot\left(\frac{\pi}{3}\right) = \frac{1}{4}\sqrt{3}s^2. \quad (6)$$

The AREAS of the INCIRCLE and CIRCUMCIRCLE are

$$A_r = \pi r^2 = \frac{1}{12}\pi s^2 \quad (7)$$

$$A_R = \pi R^2 = \frac{1}{3}\pi s^2. \quad (8)$$

Let any RECTANGLE be circumscribed about an EQUILATERAL TRIANGLE. Then

$$X + Y = Z, \quad (9)$$

where  $X$ ,  $Y$ , and  $Z$  are the AREAS of the triangles in the figure (Honsberger 1985).

Begin with an arbitrary TRIANGLE and find the EXCENTRAL TRIANGLE. Then find the EXCENTRAL TRIANGLE of that triangle, and so on. Then the resulting triangle approaches an equilateral triangle. The only RATIONAL TRIANGLE is the equilateral triangle (Conway and Guy 1996). A POLYHEDRON composed of only equilateral triangles is known as a DELTAHEDRON.

The largest equilateral triangle which can be inscribed in a UNIT SQUARE (left) has side length and area

$$s = 1 \quad (10)$$

$$A = \frac{1}{4}\sqrt{3}. \quad (11)$$

The smallest equilateral triangle which can be inscribed (right) is oriented at an angle of  $15^\circ$  and has side length and area

$$s = \sec(15^\circ) = \sqrt{6} - \sqrt{2} \quad (12)$$

$$A = 2\sqrt{3} - 3 \quad (13)$$

(Madachy 1979).

### Equilibrium Point

An equilibrium point in GAME THEORY is a set of strategies  $\{\hat{x}_1, \dots, \hat{x}_n\}$  such that the  $i$ th payoff function  $K_i(\mathbf{x})$  is larger or equal for any other  $i$ th strategy, i.e.,

$$K_i(\hat{x}_1, \dots, \hat{x}_n) \geq K_i(\hat{x}_1, \dots, \hat{x}_{i-1}, x_i, \hat{x}_{i+1}, \dots, \hat{x}_n).$$

see NASH EQUILIBRIUM

### Equilic Quadrilateral

A QUADRILATERAL in which a pair of opposite sides have the same length and are inclined at  $60^\circ$  to each other (or equivalently, satisfy  $\langle A \rangle + \langle B \rangle = 120^\circ$ ). Some interesting theorems hold for such quadrilaterals. Let  $ABCD$  be an equilic quadrilateral with  $AD = BC$  and  $\langle A \rangle + \langle B \rangle = 120^\circ$ . Then

1. The MIDPOINTS  $P$ ,  $Q$ , and  $R$  of the diagonals and the side  $CD$  always determine an EQUILATERAL TRIANGLE.
2. If EQUILATERAL TRIANGLE  $PCD$  is drawn outwardly on  $CD$ , then  $\triangle PAB$  is also an EQUILATERAL TRIANGLE.
3. If EQUILATERAL TRIANGLES are drawn on  $AC$ ,  $DC$ , and  $DB$  away from  $AB$ , then the three new VERTICES  $P$ ,  $Q$ , and  $R$  are COLLINEAR.

See Honsberger (1985) for additional theorems.

### Equinumerous

Let  $A$  and  $B$  be two classes of POSITIVE integers. Let  $A(n)$  be the number of integers in  $A$  which are less than or equal to  $n$ , and let  $B(n)$  be the number of integers in  $B$  which are less than or equal to  $n$ . Then if

$$A(n) \sim B(n),$$

$A$  and  $B$  are said to be equinumerous.

The four classes of PRIMES  $8k+1$ ,  $8k+3$ ,  $8k+5$ ,  $8k+7$  are equinumerous. Similarly, since  $8k+1$  and  $8k+5$  are both of the form  $4k+1$ , and  $8k+3$  and  $8k+7$  are both of the form  $4k+3$ ,  $4k+1$  and  $4k+3$  are also equinumerous.

### Equipollent

Two statements in LOGIC are said to be equipollent if they are deducible from each other. Two SETS with the same CARDINAL NUMBER are also said to be equipollent. The term EQUIPOTENT is sometimes used instead of equipollent.

### Equipotent

see EQUIPOLLENT

### Equipotential Curve

A curve in 2-D on which the value of a function  $f(x, y)$  is a constant. Other synonymous terms are ISARITHM and ISOPLETH.

see also LEMNISCATE

### Equiproduct Point

A point, such as interior points of a disk, such that

$$(px)(py) = [\text{const}],$$

where  $p$  is the CHORD length.

see also EQUICHORDAL POINT, EQUIRECIPROCAL POINT

### Equireciprocal Point

A point, such as the FOCI of an ELLIPSE, which satisfies

$$\frac{1}{px} + \frac{1}{py} = [\text{const}],$$

where  $p$  is the CHORD length.

see also EQUICHORDAL POINT, EQUIPRODUCT POINT

## Equirectangular Projection

A MAP PROJECTION, also called a RECTANGULAR PROJECTION, in which the horizontal coordinate is the longitude and the vertical coordinate is the latitude.

## Equiripple

A distribution of ERROR such that the ERROR remaining is always given approximately by the last term dropped.

## Equitangential Curve

see TRACTRIX

## Equivalence Class

An equivalence class is defined as a SUBSET of the form  $\{x \in X : xRa\}$ , where  $a$  is an element of  $X$  and the NOTATION " $xRy$ " is used to mean that there is an EQUIVALENCE RELATION between  $x$  and  $y$ . It can be shown that any two equivalence classes are either equal or disjoint, hence the collection of equivalence classes forms a partition of  $X$ . For all  $a, b \in X$ , we have  $aRb$  IFF  $a$  and  $b$  belong to the same equivalence class.

A set of CLASS REPRESENTATIVES is a SUBSET of  $X$  which contains EXACTLY ONE element from each equivalence class.

For  $n$  a POSITIVE INTEGER, and  $a, b$  INTEGERS, consider the CONGRUENCE  $a \equiv b \pmod{n}$ , then the equivalence classes are the sets  $\{\dots, -2n, -n, 0, n, 2n, \dots\}$ ,  $\{\dots, 1 - 2n, 1 - n, 1, 1 + n, 1 + 2n, \dots\}$  etc. The standard CLASS REPRESENTATIVES are taken to be  $0, 1, 2, \dots, n - 1$ .

see also CONGRUENCE, COSET

## References

Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, pp. 56–57, 1993.

## Equivalence Problem

see METRIC EQUIVALENCE PROBLEM

## Equivalence Relation

An equivalence relation on a set  $X$  is a SUBSET of  $X \times X$ , i.e., a collection  $R$  of ordered pairs of elements of  $X$ , satisfying certain properties. Write " $xRy$ " to mean  $(x, y)$  is an element of  $R$ , and we say " $x$  is related to  $y$ ," then the properties are

1. Reflexive:  $aRa$  for all  $a \in X$ ,
2. Symmetric:  $aRb$  IMPLIES  $bRa$  for all  $a, b \in X$

3. Transitive:  $aRb$  and  $bRc$  imply  $aRc$  for all  $a, b, c \in X$ ,

where these three properties are completely independent. Other notations are often used to indicate a relation, e.g.,  $a \equiv b$  or  $a \sim b$ .

see also EQUIVALENCE CLASS, TEICHMÜLLER SPACE

## References

Stewart, I. and Tall, D. *The Foundations of Mathematics*. Oxford, England: Oxford University Press, 1977.

## Equivalent

If  $A \Rightarrow B$  and  $B \Rightarrow A$  (i.e.,  $A \Rightarrow B \wedge B \Rightarrow A$ , where  $\Rightarrow$  denotes IMPLIES), then  $A$  and  $B$  are said to be equivalent, a relationship which is written symbolically as  $A \Leftrightarrow B$  or  $A \rightleftharpoons B$ . However, if  $A$  and  $B$  are "equivalent by definition" (i.e.,  $A$  is DEFINED to be  $B$ ), this is written  $A \equiv B$ , a notation which conflicts with that for a CONGRUENCE.

see also DEFINED, IFF, IMPLIES

## Equivalent Matrix

An  $m \times n$  MATRIX  $A$  is said to be equivalent to another  $m \times n$  MATRIX  $B$  IFF

$$B = PAQ$$

for  $P$  and  $Q$  any  $m \times n$  and  $n \times n$  MATRICES, respectively.

An ALGORITHM for making tables of PRIMES. Sequentially write down the INTEGERS from 2 to the highest number  $n$  you wish to include in the table. Cross out all numbers  $> 2$  which are divisible by 2 (every second number). Find the smallest remaining number  $> 2$ . It is 3. So cross out all numbers  $> 3$  which are divisible by 3 (every third number). Find the smallest remaining number  $> 3$ . It is 5. So cross out all numbers  $> 5$  which are divisible by 5 (every fifth number).

Continue until you have crossed out all numbers divisible by  $\lfloor \sqrt{n} \rfloor$ , where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. The numbers remaining are PRIME. This procedure is illustrated in the above diagram which sieves up to 50, and

therefore crosses out PRIMES up to  $\lfloor \sqrt{50} \rfloor = 7$ . If the procedure is then continued up to  $n$ , then the number of cross-outs gives the number of distinct PRIME factors of each number.

### Erdős-Kac Theorem

A deeper result than the HARDY-RAMANUJAN THEOREM. Let  $N(x, a, b)$  be the number of INTEGERS in  $[3, x]$  such that inequality

$$a \leq \frac{\omega(n) - \ln \ln n}{\sqrt{\ln \ln n}} \leq b$$

holds, where  $\omega(n)$  is the number of different PRIME factors of  $n$ . Then

$$\lim_{x \rightarrow \infty} N(x, a, b) = \frac{(x + o(x))}{\sqrt{2\pi}} \int_a^b e^{-t^2/2} dt.$$

The theorem is discussed in Kac (1959).

### Erdős-Mordell Theorem

If  $O$  is any point inside a TRIANGLE  $\triangle ABC$ , and  $P$ ,  $Q$ , and  $R$  are the feet of the perpendiculars from  $O$  upon the respective sides  $BC$ ,  $CA$ , and  $AB$ , then

$$OA + OB + OC \geq 2(OP + OQ + OR).$$

Oppenheim (1961) and Mordell (1962) also showed that

$$OA \times OB \times OC \geq (OQ + OR)(OR + OP)(OP + OQ).$$

### Erdős-Selfridge Function

The Erdős-Selfridge function  $g(k)$  is defined as the least integer bigger than  $k + 1$  such that all prime factors of  $\binom{g(k)}{k}$  exceed  $k$  (Ecklund *et al.* 1974). The best lower bound known is

$$g(k) \geq \exp \left( c \frac{\ln^3 k}{\ln \ln k} \right)^{1/2}$$

(Granville and Ramare 1996). Scheidler and Williams (1992) tabulated  $g(k)$  up to  $k = 140$ , and Lukes *et al.* (1997) tabulated  $g(k)$  for  $135 \leq k \leq 200$ . The values for  $n = 2, 3, \dots$  are 4, 7, 7, 23, 62, 143, 44, 159, 46, 47, 174, 2239, ... (Sloane's A046105).

### Erdős Squarefree Conjecture

The CENTRAL BINOMIAL COEFFICIENT  $\binom{2n}{n}$  is never SQUAREFREE for  $n > 4$ . This was proved true for all sufficiently large  $n$  by SÁRKÖZY'S THEOREM. Goetgheluck (1988) proved the CONJECTURE true for  $4 < n \leq 2^{42205184}$  and Vardi (1991) for  $4 < n < 2^{774840978}$ . The conjecture was proved true in its entirety by Granville and Ramare (1996).

### Erdős-Szekeres Theorem

Suppose  $a, b \in \mathbb{N}$ ,  $n = ab + 1$ , and  $x_1, \dots, x_n$  is a sequence of  $n$  REAL NUMBERS. Then this sequence contains a MONOTONIC increasing (decreasing) subsequence of  $a + 1$  terms or a MONOTONIC decreasing (increasing) subsequence of  $b + 1$  terms. DILWORTH'S LEMMA is a generalization of this theorem.

see also COMBINATORICS

### Erf

The "error function" encountered in integrating the GAUSSIAN DISTRIBUTION.

$$\operatorname{erf}(z) \equiv \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2} dt \quad (1)$$

$$= 1 - \operatorname{erfc}(z) \quad (2)$$

$$= \sqrt{\pi} \gamma\left(\frac{1}{2}, z^2\right), \quad (3)$$

where ERFC is the complementary error function and  $\gamma(x, a)$  is the incomplete GAMMA FUNCTION. It can also be defined as a MACLAURIN SERIES

$$\operatorname{erf}(z) = \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{(-1)^n z^{2n+1}}{n!(2n+1)}. \quad (4)$$

Erf has the values

$$\operatorname{erf}(0) = 0 \quad (5)$$

$$\operatorname{erf}(\infty) = 1. \quad (6)$$

It is an ODD FUNCTION

$$\operatorname{erf}(-z) = -\operatorname{erf}(z), \quad (7)$$

and satisfies

$$\operatorname{erf}(z) + \operatorname{erfc}(z) = 1. \quad (8)$$

Erf may be expressed in terms of a CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND  $M$  as

$$\operatorname{erf}(z) = \frac{2z}{\sqrt{\pi}} M\left(\frac{1}{2}, \frac{3}{2}, -z^2\right) = \frac{2z}{\sqrt{\pi}} e^{-z^2} M\left(1, \frac{3}{2}, z^2\right). \quad (9)$$

Erf is bounded by

$$\frac{1}{x + \sqrt{x^2 + 2}} < e^{x^2} \int_x^\infty e^{-t^2} dt \leq \frac{1}{x + \sqrt{x^2 + \frac{4}{\pi}}}. \quad (10)$$

Its DERIVATIVE is

$$\frac{d^n}{dz^n} \operatorname{erf}(z) = (-1)^{n-1} \frac{2}{\sqrt{\pi}} H_n(z) e^{-z^2}, \quad (11)$$

where  $H_n$  is a HERMITE POLYNOMIAL. The first DERIVATIVE is

$$\frac{d}{dz} \operatorname{erf}(z) = \frac{2}{\sqrt{\pi}} e^{-z^2/2}, \quad (12)$$

and the integral is

$$\int \operatorname{erf}(z) dz = z \operatorname{erf}(z) + \frac{e^{-z^2}}{\sqrt{\pi}}. \quad (13)$$

For  $x \ll 1$ , erf may be computed from

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \quad (14)$$

$$\begin{aligned} &= \frac{2}{\sqrt{\pi}} \int_0^x \sum_{k=0}^{\infty} \frac{(-t^2)^k}{k!} dt \\ &= \frac{2}{\sqrt{\pi}} \int_0^x \sum_{k=0}^{\infty} \frac{(-1)^k t^{2k}}{k!} dt \\ &= \frac{2}{\sqrt{\pi}} \sum_{k=0}^{\infty} \frac{x^{2k+1} (-1)^k}{k! (2k+1)} \end{aligned} \quad (15)$$

$$\begin{aligned} &= \frac{2}{\sqrt{\pi}} \left( x - \frac{1}{3} x^3 + \frac{1}{10} x^5 - \frac{1}{42} x^7 + \frac{1}{216} x^9 \right. \\ &\quad \left. - \frac{1}{1320} x^{11} + \dots \right) \end{aligned} \quad (16)$$

$$= \frac{2}{\sqrt{\pi}} e^{-x^2} x \left[ 1 + \frac{2x^2}{1 \cdot 3} + \frac{(2x)^2}{1 \cdot 3 \cdot 5} + \dots \right] \quad (17)$$

(Acton 1990). For  $x \gg 1$ ,

$$\begin{aligned} \operatorname{erf}(x) &= \frac{2}{\sqrt{\pi}} \left( \int_0^{\infty} e^{-t^2} dt - \int_x^{\infty} e^{-t^2} dt \right) \\ &= 1 - \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt. \end{aligned} \quad (18)$$

Using INTEGRATION BY PARTS gives

$$\begin{aligned} \int_x^{\infty} e^{-t^2} dt &= -\frac{1}{2} \int_x^{\infty} \frac{1}{t} d(e^{-t^2}) \\ &= -\frac{1}{2} \left[ \frac{e^{-t^2}}{t} \right]_x^{\infty} - \frac{1}{2} \int_x^{\infty} \frac{e^{-t^2}}{t^2} dt \\ &= \frac{e^{-x^2}}{2x} + \frac{1}{4} \int_x^{\infty} \frac{1}{t^3} d(e^{-t^2}) \\ &= \frac{e^{-x^2}}{2x} - \frac{e^{-x^2}}{4x^3} - \dots, \end{aligned} \quad (19)$$

so

$$\operatorname{erf}(x) = 1 - \frac{e^{-x^2}}{\sqrt{\pi} x} \left( 1 - \frac{1}{2x^2} - \dots \right) \quad (20)$$

and continuing the procedure gives the ASYMPTOTIC SERIES

$$\begin{aligned} \operatorname{erf}(x) &= 1 - \frac{e^{-x^2}}{\sqrt{\pi}} \left( x^{-1} - \frac{1}{2} x^{-3} \right. \\ &\quad \left. + \frac{3}{4} x^{-5} - \frac{15}{8} x^{-7} + \frac{105}{16} x^{-9} + \dots \right). \end{aligned} \quad (21)$$

A COMPLEX generalization of erf is defined as

$$w(z) \equiv e^{-z^2} \operatorname{erfc}(-iz) \quad (22)$$

$$= e^{-z^2} \left( 1 + \frac{2i}{\sqrt{\pi}} + \frac{2i}{\sqrt{\pi}} \int_0^z e^{t^2} dt \right) \quad (23)$$

$$= \frac{i}{\pi} \int_{-\infty}^{\infty} \frac{e^{-t^2}}{z-t} dt = \frac{2iz}{\pi} \int_0^{\infty} \frac{e^{-t^2}}{z^2 - t^2} dt. \quad (24)$$

#### Erfc

The "complementary error function"

$$\operatorname{erfc}(x) \equiv \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt \quad (1)$$

$$= 1 - \operatorname{erf}(x) \quad (2)$$

$$= \sqrt{\pi} \gamma\left(\frac{1}{2}, x^2\right), \quad (3)$$

where  $\gamma$  is the incomplete GAMMA FUNCTION. It has the values

$$\operatorname{erfc}(0) = 1 \quad (4)$$

$$\operatorname{erfc}(\infty) = 0 \quad (5)$$

$$\operatorname{erfc}(-x) = 2 - \operatorname{erfc}(x) \quad (6)$$

$$\int_0^{\infty} \operatorname{erfc}(x) dx = \frac{1}{\sqrt{\pi}} \quad (7)$$

$$\int_0^{\infty} \operatorname{erfc}^2(x) dx = \frac{2 - \sqrt{2}}{\sqrt{\pi}}. \quad (8)$$

A generalization is obtained from the differential equation

$$\frac{d^2 y}{dz^2} + 2z \frac{dy}{dz} - 2ny = 0. \quad (9)$$

The general solution is then

$$y = A \operatorname{erfc}_n(z) + B \operatorname{erfc}_n(-z), \quad (10)$$

where  $\operatorname{erfc}_n(z)$  is the erfc integral. For integral  $n \geq 1$ ,

$$\operatorname{erfc}_n(z) = \underbrace{\int \dots \int}_n \operatorname{erfc}(z) dz \quad (11)$$

$$= \frac{2}{\sqrt{\pi}} \int_0^{\infty} \frac{(t-z)^2}{n!} e^{-t^2} dt. \quad (12)$$

The definition can be extended to  $n = -1$  and 0 using

$$\operatorname{erfc}_{-1}(z) = \frac{2}{\sqrt{\pi}} e^{-z^2} \quad (13)$$

$$\operatorname{erfc}_0(z) = \operatorname{erfc}(z). \quad (14)$$

$$\operatorname{erfi}(z) \equiv -i \operatorname{erf}(iz).$$

see also ERF, ERFI

### Ergodic Measure

An ENDOMORPHISM is called ergodic if it is true that  $T^{-1}A = A$  IMPLIES  $m(A) = 0$  or 1, where  $T^{-1}A = \{x \in X : T(x) \in A\}$ . Examples of ergodic endomorphisms include the MAP  $X \rightarrow 2x \bmod 1$  on the unit interval with LEBESGUE MEASURE, certain AUTOMORPHISMS of the TORUS, and "Bernoulli shifts" (and more generally "Markov shifts").

Given a MAP  $T$  and a SIGMA ALGEBRA, there may be many ergodic measures. If there is only one ergodic measure, then  $T$  is called uniquely ergodic. An example of a uniquely ergodic transformation is the MAP  $x \mapsto x + a \bmod 1$  on the unit interval when  $a$  is irrational. Here, the unique ergodic measure is LEBESGUE MEASURE.

### Ergodic Theory

Ergodic theory can be described as the statistical and qualitative behavior of measurable group and semigroup actions on MEASURE SPACES. The GROUP is most commonly  $\mathbb{N}$ ,  $\mathbb{R}$ ,  $\mathbb{R}^+$ , and  $\mathbb{Z}$ .

Ergodic theory had its origins in the work of Boltzmann in statistical mechanics. Its mathematical origins are due to von Neumann, Birkhoff, and Koopman in the 1930s. It has since grown to be a huge subject and has applications not only to statistical mechanics, but also to number theory, differential geometry, functional analysis, etc. There are also many internal problems

(e.g., ergodic theory being applied to ergodic theory) which are interesting.

### Error

The difference between a quantity and its estimated or measured quantity.

see also ABSOLUTE ERROR, PERCENTAGE ERROR, RELATIVE ERROR

**Error-Correcting Code**

An error-correcting code is an algorithm for expressing a sequence of numbers such that any errors which are introduced can be detected and corrected (within certain limitations) based on the remaining numbers. The study of error-correcting codes and the associated mathematics is known as CODING THEORY.

Error detection is much simpler than error correction, and one or more "check" digits are commonly embedded in credit card numbers in order to detect mistakes. Early space probes like Mariner used a type of error-correcting code called a block code, and more recent space probes use convolution codes. Error-correcting codes are also used in CD players, high speed modems, and cellular phones. Modems use error detection when they compute CHECKSUMS, which are sums of the digits in a given transmission modulo some number. The ISBN used to identify books also incorporates a check DIGIT.

A powerful check for 13 DIGIT numbers consists of the following. Write the number as a string of DIGITS  $a_1 a_2 a_3 \cdots a_{13}$ . Take  $a_1 + a_3 + \cdots + a_{13}$  and double. Now add the number of DIGITS in ODD positions which are  $> 4$  to this number. Now add  $a_2 + a_4 + \cdots + a_{12}$ . The check number is then the number required to bring the last DIGIT to 0. This scheme detects all single DIGIT errors and all TRANSPOSITIONS of adjacent DIGITS except 0 and 9.

**Error Curve**

see GAUSSIAN FUNCTION

**Error Function**

see ERF, ERFC

**Error Function Distribution**

A NORMAL DISTRIBUTION with MEAN 0.

$$P(x) = \frac{h}{\sqrt{\pi}} e^{-h^2 x^2}. \quad (1)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = e^{-t^2/(4h^2)}. \quad (2)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = 0 \quad (3)$$

$$\sigma^2 = \frac{1}{2h^2} \quad (4)$$

$$\gamma_1 = 0 \quad (5)$$

$$\gamma_2 = 0. \quad (6)$$

The CUMULANTS are

$$\kappa_1 = 0 \quad (7)$$

$$\kappa_2 = \frac{1}{2h^2} \quad (8)$$

$$\kappa_n = 0 \quad (9)$$

for  $n \geq 3$ .

**Error Propagation**

Given a FORMULA  $y = f(x)$  with an ABSOLUTE ERROR in  $x$  of  $dx$ , the ABSOLUTE ERROR is  $dy$ . The RELATIVE ERROR is  $dy/y$ . If  $x = f(u, v)$ , then

$$x_i - \bar{x} = (u_i - \bar{u}) \frac{\partial x}{\partial u} + (v_i - \bar{v}) \frac{\partial x}{\partial v} + \cdots, \quad (1)$$

so

$$\begin{aligned} \sigma_x^2 &\equiv \frac{1}{N-1} \sum_i (x_i - \bar{x})^2 \\ &= \frac{1}{N-1} \sum_i \left[ (u_i - \bar{u})^2 \left( \frac{\partial x}{\partial u} \right)^2 + (v_i - \bar{v})^2 \left( \frac{\partial x}{\partial v} \right)^2 \right. \\ &\quad \left. + 2(u_i - \bar{u})(v_i - \bar{v}) \left( \frac{\partial x}{\partial u} \right) \left( \frac{\partial x}{\partial v} \right) + \cdots \right]. \end{aligned} \quad (2)$$

The definitions of VARIANCE and COVARIANCE then give

$$\sigma_u^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (u_i - \bar{u})^2 \quad (3)$$

$$\sigma_v^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (v_i - \bar{v})^2 \quad (4)$$

$$\sigma_{uv}^2 \equiv \frac{1}{N-1} \sum_{i=1}^N (u_i - \bar{u})(v_i - \bar{v}), \quad (5)$$

so

$$\begin{aligned} \sigma_x^2 &= \sigma_u^2 \left( \frac{\partial x}{\partial u} \right)^2 + \sigma_v^2 \left( \frac{\partial x}{\partial v} \right)^2 \\ &\quad + 2\sigma_{uv} \left( \frac{\partial x}{\partial u} \right) \left( \frac{\partial x}{\partial v} \right) + \cdots \end{aligned} \quad (6)$$

If  $u$  and  $v$  are uncorrelated, then  $\sigma_{uv} = 0$  so

$$\sigma_x^2 = \sigma_u^2 \left( \frac{\partial x}{\partial u} \right)^2 + \sigma_v^2. \quad (7)$$

Now consider addition of quantities with errors. For  $x = au \pm bv$ ,  $\partial x/\partial u = a$  and  $\partial x/\partial v = \pm b$ , so

$$\sigma_x^2 = a^2 \sigma_u^2 + b^2 \sigma_v^2 \pm 2ab\sigma_{uv}. \quad (8)$$

For division of quantities with  $x = \pm au/v$ ,  $\partial x/\partial u = \pm a/v$  and  $\partial x/\partial v = \mp au/v^2$ , so

$$\sigma_x^2 = \frac{a^2}{v^2} \sigma_u^2 + \frac{a^2 u^2}{\sigma_v^4} - 2 \frac{a}{v} \frac{au}{v^2} \sigma_{uv}. \quad (9)$$

$$\begin{aligned} \left(\frac{\sigma_x}{x}\right)^2 &= \frac{a^2}{v^2} \frac{v^2}{a^2 u^2} \sigma_u^2 + \frac{a^2 u^2}{v^4} \frac{v^2}{a^2 u^2} - 2 \left(\frac{a}{v}\right) \left(\frac{au}{v^2}\right) \sigma_{uv}^2 \\ &= \left(\frac{\sigma_u}{u}\right)^2 + \left(\frac{\sigma_v}{v}\right)^2 - 2 \left(\frac{\sigma_{uv}}{u}\right) \left(\frac{\sigma_{uv}}{v}\right). \end{aligned} \quad (10)$$

For exponentiation of quantities with

$$x = a^{\pm bu} = (e^{\ln a})^{\pm bu} = e^{\pm b(\ln a)u}, \quad (11)$$

$$\frac{\partial x}{\partial u} = \pm b(\ln a) e^{\pm b \ln a u} = \pm b(\ln a)x, \quad (12)$$

so

$$\sigma_x = \sigma_u b(\ln a)x \quad (13)$$

$$\frac{\sigma_x}{x} = b \ln a \sigma_u. \quad (14)$$

If  $a = e$ , then

$$\frac{\sigma_x}{x} = b \sigma_u. \quad (15)$$

For LOGARITHMS of quantities with  $x = a \ln(\pm bu)$ ,  $\partial x/\partial u = a(\pm b)/(\pm bu) = a/u$ , so

$$\sigma_x^2 = \sigma_u^2 \left(\frac{a}{u}\right)^2 \quad (16)$$

$$\sigma_x = a \frac{\sigma_u}{u}. \quad (17)$$

For multiplication with  $x = \pm auv$ ,  $\partial x/\partial u = \pm av$  and  $\partial x/\partial v = \pm au$ , so

$$\sigma_x^2 = a^2 v^2 \sigma_u^2 + a^2 u^2 \sigma_v^2 + 2a^2 uv \sigma_{uv}^2 \quad (18)$$

$$\begin{aligned} \left(\frac{\sigma_x}{x}\right)^2 &= \frac{a^2 v^2}{a^2 u^2 v^2} \sigma_u^2 + \frac{a^2 u^2}{a^2 u^2 v^2} \sigma_v^2 + \frac{2a^2 uv}{a^2 u^2 v^2} \sigma_{uv}^2 \\ &= \left(\frac{\sigma_u}{u}\right)^2 + \left(\frac{\sigma_v}{v}\right)^2 + 2 \left(\frac{\sigma_{uv}}{u}\right) \left(\frac{\sigma_{uv}}{v}\right). \end{aligned} \quad (19)$$

For POWERS, with  $x = au^{\pm b}$ ,  $\partial x/\partial u = \pm abu^{\pm b-1} = \pm bx/u$ , so

$$\sigma_x^2 = \sigma_u^2 \frac{b^2 x^2}{u^2} \quad (20)$$

$$\frac{\sigma_x}{x} = b \frac{\sigma_u}{u}. \quad (21)$$

#### Estimate

An estimate is an educated guess for an unknown quantity or outcome based on known information. The making of estimates is an important part of statistics, since care is needed to provide as accurate an estimate as possible using as little input data as possible. Often, an estimate for the uncertainty  $\Delta E$  of an estimate  $E$  can also be determined statistically. A rule that tells how to calculate an estimate based on the measurements contained in a sample is called an ESTIMATOR.

#### Estimator

An estimator is a rule that tells how to calculate an ESTIMATE based on the measurements contained in a sample. For example, the "sample MEAN" AVERAGE  $\bar{x}$  is an estimator for the population MEAN  $\mu$ .

The mean square error of an estimator  $\tilde{\theta}$  is defined by

$$\text{MSE} \equiv \langle (\tilde{\theta} - \theta)^2 \rangle.$$

Let  $B$  be the BIAS, then

$$\begin{aligned} \text{MSE} &= \langle [(\tilde{\theta} - \langle \tilde{\theta} \rangle) + B(\tilde{\theta})]^2 \rangle \\ &= \langle (\tilde{\theta} - \langle \tilde{\theta} \rangle)^2 \rangle + B^2(\tilde{\theta}) \equiv V(\tilde{\theta}) + B^2(\tilde{\theta}), \end{aligned}$$

where  $V$  is the estimator VARIANCE.

**Euclid Number**

The  $n$ th Euclid number is defined by

$$E_n \equiv 1 + \prod_{i=1}^n p_i,$$

where  $p_i$  is the  $i$ th PRIME. The first few  $E_n$  are 3, 7, 31, 211, 2311, 30031, 510511, 9699691, 223092871, 6469693231, ... (Sloane's A006862). The largest factor of  $E_n$  are 3, 7, 31, 211, 2311, 509, 277, 27953, ... (Sloane's A002585). The  $n$  of the first few PRIME Euclid numbers  $E_n$  are 1, 2, 3, 4, 5, 11, 75, 171, 172, 384, 457, 616, 643, ... (Sloane's A014545) up to a search limit of 700. It is not known if there are an INFINITE number of PRIME Euclid numbers (Guy 1994, Ribenboim 1996).

**Euclid's Postulates**

1. A straight LINE SEGMENT can be drawn joining any two points.
2. Any straight LINE SEGMENT can be extended indefinitely in a straight LINE.
3. Given any straight LINE SEGMENT, a CIRCLE can be drawn having the segment as RADIUS and one endpoint as center.
4. All RIGHT ANGLES are congruent.
5. If two lines are drawn which intersect a third in such a way that the sum of the inner angles on one side is less than two RIGHT ANGLES, then the two lines inevitably must intersect each other on that side if extended far enough. This postulate is equivalent to what is known as the PARALLEL POSTULATE.

Euclid's fifth postulate cannot be proven as a theorem, although this was attempted by many people. Euclid himself used only the first four postulates (“ABSOLUTE GEOMETRY”) for the first 28 propositions of the *Elements*, but was forced to invoke the PARALLEL POSTULATE on the 29th. In 1823, Janos Bolyai and Nicolai Lobachevsky independently realized that entirely self-consistent “NON-EUCLIDEAN GEOMETRIES” could be created in which the parallel postulate *did not hold*. (Gauss had also discovered but suppressed the existence of non-Euclidean geometries.)

**Euclid's Principle**

see EUCLID'S THEOREMS

**Euclid's Theorems**

A theorem sometimes called “Euclid's First Theorem” or EUCLID'S PRINCIPLE states that if  $p$  is a PRIME and  $p|ab$ , then  $p|a$  or  $p|b$  (where  $|$  means DIVIDES). A COROLLARY is that  $p|a^n \Rightarrow p|a$  (Conway and Guy 1996). The FUNDAMENTAL THEOREM OF ARITHMETIC is another COROLLARY (Hardy and Wright 1979).

Euclid's Second Theorem states that the number of PRIMES is INFINITE. This theorem, also called the INFINITUDE OF PRIMES theorem, was proved by Euclid in Proposition IX.20 of the *Elements*. Ribenboim (1989) gives nine (and a half) proofs of this theorem. Euclid's elegant proof proceeds as follows. Given a finite sequence of consecutive PRIMES 2, 3, 5, ...,  $p$ , the number

$$N = 2 \cdot 3 \cdot 5 \cdots p + 1, \quad (1)$$

known as the  $i$ th EUCLID NUMBER when  $p = p_i$  is the  $i$ th PRIME, is either a new PRIME or the product of PRIMES.

If  $N$  is a PRIME, then it must be greater than the previous PRIMES, since one plus the product of PRIMES must be greater than each PRIME composing the product. Now, if  $N$  is a product of PRIMES, then at least one of the PRIMES must be greater than  $p$ . This can be shown as follows. If  $N$  is COMPOSITE and not greater than  $p$ , then one of its factors (say  $F$ ) must be one of the PRIMES in the sequence,  $2, 3, 5, \dots, p$ . It therefore DIVIDES the product  $2 \cdot 3 \cdot 5 \cdots p$ . However, since it is a factor of  $N$ , it also DIVIDES  $N$ . But a number which DIVIDES two numbers  $a$  and  $b < a$  also DIVIDES their difference  $a - b$ , so  $F$  must also divide

$$N - (2 \cdot 3 \cdot 5 \cdots p) = (2 \cdot 3 \cdot 5 \cdots p + 1) - (2 \cdot 3 \cdot 5 \cdots p) = 1. \quad (2)$$

However, in order to divide 1,  $F$  must be 1, which is contrary to the assumption that it is a PRIME in the sequence  $2, 3, 5, \dots$ . It therefore follows that if  $N$  is composite, it has at least one factor greater than  $p$ . Since  $N$  is either a PRIME greater than  $p$  or contains a factor greater than  $p$ , a PRIME larger than the largest in the finite sequence can always be found, so there are an infinite number of PRIMES. Hardy (1967) remarks that this proof is "as fresh and significant as when it was discovered" so that "two thousand years have not written a wrinkle" on it.

A similar argument shows that  $p! \pm 1$  is PRIME, and

$$1 \cdot 3 \cdot 5 \cdot 7 \cdots p + 1 \quad (3)$$

must be either PRIME or be divisible by a PRIME  $> p$ . Kummer used a variation of this proof, which is also a proof by contradiction. It assumes that there exist only a finite number of PRIMES  $N = p_1, p_2, \dots, p_r$ . Now consider  $N - 1$ . It must be a product of PRIMES, so it has a PRIME divisor  $p_i$  in common with  $N$ . Therefore,  $p_i | N - (N - 1) = 1$  which is nonsense, so we have proved the initial assumption is wrong by contradiction.

It is also true that there are runs of COMPOSITE NUMBERS which are arbitrarily long. This can be seen by defining

$$n \equiv j! = \prod_{i=1}^j i, \quad (4)$$

where  $j!$  is a FACTORIAL. Then the  $j - 1$  consecutive numbers  $n + 2, n + 3, \dots, n + j$  are COMPOSITE, since

$$n + 2 = (1 \cdot 2 \cdots j) + 2 = 2(1 \cdot 3 \cdot 4 \cdots n + 1) \quad (5)$$

$$n + 3 = (1 \cdot 2 \cdots j) + 3 = 3(1 \cdot 2 \cdot 4 \cdot 5 \cdots n + 1) \quad (6)$$

$$n + j = (1 \cdot 2 \cdots j) + j = j[1 \cdot 2 \cdots (j - 1) + 1]. \quad (7)$$

Guy (1981, 1988) points out that while  $p_1 p_2 \cdots p_n + 1$  is not necessarily PRIME, letting  $q$  be the next PRIME after  $p_1 p_2 \cdots p_n + 1$ , the number  $q - p_1 p_2 \cdots p_n + 1$  is almost always a PRIME, although it has not been proven that this must *always* be the case.

#### Euclidean Algorithm

An ALGORITHM for finding the GREATEST COMMON DIVISOR of two numbers  $a$  and  $b$ , also called Euclid's algorithm. It is an example of a P-PROBLEM whose time complexity is bounded by a quadratic function of the length of the input values (Banach and Shallit). Let  $a = bq + r$ , then find a number  $u$  which DIVIDES both  $a$  and  $b$  (so that  $a = su$  and  $b = tu$ ), then  $u$  also DIVIDES  $r$  since

$$r = a - bq = su - qtu = (s - qt)u. \quad (1)$$

Similarly, find a number  $v$  which DIVIDES  $b$  and  $r$  (so that  $b = s'v$  and  $r = t'v$ ), then  $v$  DIVIDES  $a$  since

$$a = bq + r = s'vq + t'v = (s'q + t')v. \quad (2)$$

Therefore, every common DIVISOR of  $a$  and  $b$  is a common DIVISOR of  $b$  and  $r$ , so the procedure can be iterated as follows

$$a = bq_1 + r_1 \quad (3)$$

$$b = q_2 r_1 + r_2 \quad (4)$$

$$r_1 = q_3 r_2 + r_3 \quad (5)$$

$$r_{n-2} = q_n r_{n-1} + r_n \quad (6)$$

$$r_{n-1} = q_{n+1} r_n, \quad (7)$$

where  $r_n$  is  $\text{GCD}(a, b) \equiv (a, b)$ . Lamé showed that the number of steps needed to arrive at the GREATEST COMMON DIVISOR for two numbers less than  $N$  is

$$\text{steps} \leq \frac{\log_{10} N}{\log_{10} \phi} + \frac{\log_{10} \sqrt{5}}{\log_{10} \phi} \quad (8)$$

where  $\phi$  is the GOLDEN MEAN, or  $\leq 5$  times the number of digits in the smaller number. Numerically, Lamé's expression evaluates to

$$\text{steps} \leq 4.785 \log_{10} N + 1.6723. \quad (9)$$

As shown by LAMÉ'S THEOREM, the worst case occurs when the ALGORITHM is applied to two consecutive FIBONACCI NUMBERS. Heilbronn showed that the average number of steps is  $12 \ln 2 / \pi^2 \log_{10} n = 0.843 \log_{10} n$  for all pairs  $(n, b)$  with  $b < n$ . Kronecker showed that the shortest application of the ALGORITHM uses least absolute remainders. The QUOTIENTS obtained are distributed as shown in the following table (Wagon 1991).

Quotient	%
1	41.5
2	17.0
3	9.3

For details, see Uspensky and Heaslet (1939) or Knuth (1973). Let  $T(m, n)$  be the number of divisions required to compute  $\text{GCD}(m, n)$  using the Euclidean algorithm, and define  $T(m, 0) = 0$  if  $m \geq 0$ . Then

$$T(m, n) = \begin{cases} 1 + T(n, m \bmod n) & \text{for } m \geq n \\ 1 + T(n, m) & \text{for } m < n. \end{cases} \quad (10)$$

Define the functions

$$T(n) = \frac{1}{n} \sum_{0 \leq m < n} T(m, n) \quad (11)$$

$$\tau(n) = \frac{1}{\phi(n)} \sum_{\substack{0 \leq m < n \\ \text{GCD}(m, n)=1}} T(m, n) \quad (12)$$

$$A(N) = \frac{1}{N^2} \sum_{\substack{1 \leq m \leq N \\ 1 \leq n \leq N}} T(m, n), \quad (13)$$

where  $\phi$  is the TOTIENT FUNCTION,  $T(n)$  is the average number of divisions when  $n$  is fixed and  $m$  chosen at random,  $\tau(n)$  is the average number of divisions when  $n$  is fixed and  $m$  is a random number coprime to  $n$ , and  $A(N)$  is the average number of divisions when  $m$  and  $n$  are both chosen at random in  $[1, N]$ . Norton (1990) showed that

$$T(n) = \frac{12 \ln 2}{\pi^2} \left[ \ln n - \sum_{d|n} \frac{\Lambda(d)}{d} \right] + C + \frac{1}{n} \sum_{d|n} \phi(d) \mathcal{O}(d^{-1/6+\epsilon}), \quad (14)$$

where  $\Lambda$  is the VON MANGOLDT FUNCTION and  $C$  is PORTER'S CONSTANT. Porter (1975) showed that

$$\tau(n) = \frac{12 \ln 2}{\pi^2} \ln n + C + \mathcal{O}(n^{-1/6} + \epsilon), \quad (15)$$

and Norton (1990) proved that

$$A(N) = \frac{12 \ln 2}{\pi^2} \left[ \ln N - \frac{1}{2} + \frac{6}{\pi^2} \zeta'(2) \right] + C - \frac{1}{2} + \mathcal{O}(N^{-1/6+\epsilon}). \quad (16)$$

There exist 22 QUADRATIC FIELDS in which there is a Euclidean algorithm (Inkeri 1947).

## Euler's Addition Theorem

Let  $g(x) \equiv (1 - x^2)(1 - k^2 x^2)$ . Then

$$\int_0^a \frac{dx}{\sqrt{g(x)}} + \int_0^b \frac{dx}{\sqrt{g(x)}} = \int_0^c \frac{dx}{\sqrt{g(x)}},$$

where

$$c \equiv \frac{b\sqrt{g(a)} + a\sqrt{g(b)}}{\sqrt{1 - k^2 a^2 b^2}}.$$

## Euler Angles

According to EULER'S ROTATION THEOREM, any ROTATION may be described using three ANGLES. If the ROTATIONS are written in terms of ROTATION MATRICES  $B$ ,  $C$ , and  $D$ , then a general ROTATION  $A$  can be written as

$$A = BCD. \quad (1)$$

The three angles giving the three rotation matrices are called Euler angles. There are several conventions for Euler angles, depending on the axes about which the rotations are carried out. Write the MATRIX  $A$  as

$$A \equiv \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}. \quad (2)$$

In the so-called "x-convention," illustrated above,

$$D \equiv \begin{bmatrix} \cos \phi & \sin \phi & 0 \\ -\sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (3)$$

$$C \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{bmatrix} \quad (4)$$

$$B \equiv \begin{bmatrix} \cos \psi & \sin \psi & 0 \\ -\sin \psi & \cos \psi & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad (5)$$

so

$$\begin{aligned} a_{11} &= \cos \psi \cos \phi - \cos \theta \sin \phi \sin \psi \\ a_{12} &= \cos \psi \sin \phi + \cos \theta \cos \phi \sin \psi \\ a_{13} &= \sin \psi \sin \theta \\ a_{21} &= -\sin \psi \cos \phi - \cos \theta \sin \phi \cos \psi \\ a_{22} &= -\sin \psi \sin \phi + \cos \theta \cos \phi \cos \psi \\ a_{23} &= \cos \psi \sin \theta \\ a_{31} &= \sin \theta \sin \phi \\ a_{32} &= -\sin \theta \cos \phi \\ a_{33} &= \cos \theta \end{aligned}$$

To obtain the components of the ANGULAR VELOCITY  $\omega$  in the body axes, note that for a MATRIX

$$A \equiv [A_1 \quad A_2 \quad A_3], \quad (6)$$

it is true that

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} \omega_x \\ \omega_y \\ \omega_z \end{bmatrix} = \begin{bmatrix} a_{11}\omega_x + a_{12}\omega_y + a_{13}\omega_z \\ a_{21}\omega_x + a_{22}\omega_y + a_{23}\omega_z \\ a_{31}\omega_x + a_{32}\omega_y + a_{33}\omega_z \end{bmatrix} \quad (7)$$

$$= A_1\omega_x + A_2\omega_y + A_3\omega_z. \quad (8)$$

Now,  $\omega_z$  corresponds to rotation about the  $\phi$  axis, so look at the  $\omega_z$  component of  $A\omega$ ,

$$\omega_\phi = A_1\omega_z = \begin{bmatrix} \sin \psi \sin \theta \\ \cos \psi \sin \theta \\ \cos \theta \end{bmatrix} \dot{\phi}. \quad (9)$$

The line of nodes corresponds to a rotation by  $\theta$  about the  $\xi$ -axis, so look at the  $\omega_\xi$  component of  $B\omega$ ,

$$\omega_\theta = B_1\omega_\xi = B_1\dot{\theta} = \begin{bmatrix} \cos \psi \\ -\sin \psi \\ 0 \end{bmatrix} \dot{\theta}. \quad (10)$$

Similarly, to find rotation by  $\psi$  about the remaining axis, look at the  $\omega_\psi$  component of  $B\omega$ ,

$$\omega_\psi = B_3\omega_\psi = B_3\dot{\psi} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \dot{\psi}. \quad (11)$$

Combining the pieces gives

$$\omega = \begin{bmatrix} \sin \psi \sin \theta \dot{\phi} + \cos \psi \dot{\theta} \\ \cos \psi \sin \theta \dot{\phi} - \sin \psi \dot{\theta} \\ \cos \theta \dot{\phi} + \dot{\psi} \end{bmatrix} \quad (12)$$

For more details, see Goldstein (1980, p. 176) and Landau and Lifschitz (1976, p. 111).

The x-convention Euler angles are given in terms of the CAYLEY-KLEIN PARAMETERS by

$$\begin{aligned} \phi &= -2i \ln \left( \pm \frac{\alpha^{1/2} \gamma^{1/4}}{\beta^{1/4} (1 + \beta \gamma)^{1/4}} \right), \\ &- 2i \ln \left( \pm \frac{i \alpha^{1/2} \gamma^{1/4}}{\beta^{1/4} (1 + \beta \gamma)^{1/4}} \right) \end{aligned} \quad (13)$$

$$\begin{aligned} \psi &= -2i \ln \left( \pm \frac{\alpha^{1/2} \beta^{1/4}}{\gamma^{1/4} (1 + \beta \gamma)^{1/4}} \right), \\ &- 2i \ln \left( \pm \frac{i \alpha^{1/2} \beta^{1/4}}{\gamma^{1/4} (1 + \beta \gamma)^{1/4}} \right) \end{aligned} \quad (14)$$

$$\theta = \pm 2 \cos^{-1} (\pm \sqrt{1 + \beta \gamma}). \quad (15)$$

In the "y-convention,"

$$\phi_x \equiv \phi_y + \frac{1}{2} \pi \quad (16)$$

$$\psi_x \equiv \psi_y - \frac{1}{2} \pi. \quad (17)$$

Therefore,

$$\sin \phi_x = \cos \phi_y \quad (18)$$

$$\cos \phi_x = -\sin \phi_y \quad (19)$$

$$\sin \psi_x = -\cos \psi_y \quad (20)$$

$$\cos \psi_x = \sin \psi_y \quad (21)$$

$$D \equiv \begin{bmatrix} -\sin \phi & \cos \phi & 0 \\ -\cos \phi & -\sin \phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (22)$$

$$C \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & \sin \theta \\ 0 & -\sin \theta & \cos \theta \end{bmatrix} \quad (23)$$

$$B \equiv \begin{bmatrix} \sin \psi & -\cos \psi & 0 \\ \cos \psi & \sin \psi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (24)$$

and A is given by

$$\begin{aligned} a_{11} &= -\sin \psi \sin \phi + \cos \theta \cos \phi \cos \psi \\ a_{12} &= \sin \psi \cos \phi + \cos \theta \sin \phi \cos \psi \\ a_{13} &= -\cos \psi \sin \theta \\ a_{21} &= -\cos \psi \sin \phi - \cos \theta \cos \phi \sin \psi \\ a_{22} &= \cos \psi \cos \phi - \cos \theta \sin \phi \sin \psi \\ a_{23} &= \sin \psi \sin \theta \\ a_{31} &= \sin \theta \cos \phi \\ a_{32} &= \sin \theta \sin \phi \\ a_{33} &= \cos \theta. \end{aligned}$$

In the "xyz" (pitch-roll-yaw) convention,  $\theta$  is pitch,  $\psi$  is roll, and  $\phi$  is yaw.

$$D \equiv \begin{bmatrix} \cos \phi & \sin \phi & 0 \\ -\sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (25)$$

$$C \equiv \begin{bmatrix} \cos \theta & 0 & -\sin \theta \\ 0 & 1 & 0 \\ \sin \theta & 0 & \cos \theta \end{bmatrix} \quad (26)$$

$$B \equiv \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \psi & \sin \psi \\ 0 & -\sin \psi & \cos \psi \end{bmatrix} \quad (27)$$

and A is given by

$$\begin{aligned} a_{11} &= \cos \theta \cos \phi \\ a_{12} &= \cos \theta \sin \phi \\ a_{13} &= -\sin \theta \\ a_{21} &= \sin \psi \sin \theta \cos \phi - \cos \psi \sin \phi \\ a_{22} &= \sin \psi \sin \theta \sin \phi + \cos \psi \cos \phi \\ a_{23} &= \cos \theta \sin \psi \\ a_{31} &= \cos \psi \sin \theta \cos \phi + \sin \psi \sin \phi \\ a_{32} &= \cos \psi \sin \theta \sin \phi - \sin \psi \cos \phi \\ a_{33} &= \cos \theta \cos \psi. \end{aligned}$$

A set of parameters sometimes used instead of angles are the EULER PARAMETERS  $e_0, e_1, e_2$  and  $e_3$ , defined by

$$e_0 \equiv \cos \left( \frac{\phi}{2} \right) \quad (28)$$

$$\mathbf{e} \equiv \begin{bmatrix} e_1 \\ e_2 \\ e_3 \end{bmatrix} = \hat{\mathbf{n}} \sin \left( \frac{\phi}{2} \right). \quad (29)$$

Using EULER PARAMETERS (which are QUATERNIONS), an arbitrary ROTATION MATRIX can be described by

$$\begin{aligned} a_{11} &= e_0^2 + e_1^2 - e_2^2 - e_3^2 \\ a_{12} &= 2(e_1 e_2 + e_0 e_3) \\ a_{13} &= 2(e_1 e_3 - e_0 e_2) \\ a_{21} &= 2(e_1 e_2 - e_0 e_3) \\ a_{22} &= e_0^2 - e_1^2 + e_2^2 - e_3^2 \\ a_{23} &= 2(e_2 e_3 + e_0 e_1) \\ a_{31} &= 2(e_1 e_3 + e_0 e_2) \\ a_{32} &= 2(e_2 e_3 - e_0 e_1) \\ a_{33} &= e_0^2 - e_1^2 - e_2^2 + e_3^2 \end{aligned}$$

(Goldstein 1960, p. 153).

If the coordinates of two pairs of  $n$  points  $\mathbf{x}_i$  and  $\mathbf{x}'_i$  are known, one rotated with respect to the other, then the Euler rotation matrix can be obtained in a straightforward manner using LEAST SQUARES FITTING. Write the points as arrays of vectors, so

$$[\mathbf{x}'_1 \cdots \mathbf{x}'_n] = \mathbf{A} [\mathbf{x}_1 \cdots \mathbf{x}_n]. \quad (30)$$

Writing the arrays of vectors as matrices gives

$$\mathbf{X}' = \mathbf{A} \mathbf{X} \quad (31)$$

$$\mathbf{X}' \mathbf{X}^T = \mathbf{A} \mathbf{X} \mathbf{X}^T, \quad (32)$$

and solving for A gives

$$\mathbf{A} = \mathbf{X}' \mathbf{X}^T (\mathbf{X} \mathbf{X}^T)^{-1}. \quad (33)$$

However, we want the angles  $\theta, \phi$ , and  $\psi$ , not their combinations contained in the MATRIX A. Therefore, write the  $3 \times 3$  MATRIX

$$\mathbf{A} = \begin{bmatrix} f_1(\theta, \phi, \psi) & f_2(\theta, \phi, \psi) & f_3(\theta, \phi, \psi) \\ f_4(\theta, \phi, \psi) & f_5(\theta, \phi, \psi) & f_6(\theta, \phi, \psi) \\ f_7(\theta, \phi, \psi) & f_8(\theta, \phi, \psi) & f_9(\theta, \phi, \psi) \end{bmatrix} \quad (34)$$

as a  $1 \times 9$  VECTOR

$$\mathbf{f} = \begin{bmatrix} f_1(\theta, \phi, \psi) \\ \vdots \\ f_9(\theta, \phi, \psi) \end{bmatrix}. \quad (35)$$

Now set up the matrices

$$\begin{bmatrix} \frac{\partial f_1}{\partial \theta} \big|_{\theta_i, \phi_i, \psi_i} & \frac{\partial f_1}{\partial \phi} \big|_{\theta_i, \phi_i, \psi_i} & \frac{\partial f_1}{\partial \psi} \big|_{\theta_i, \phi_i, \psi_i} \\ \vdots & \vdots & \vdots \\ \frac{\partial f_9}{\partial \theta} \big|_{\theta_i, \phi_i, \psi_i} & \frac{\partial f_9}{\partial \phi} \big|_{\theta_i, \phi_i, \psi_i} & \frac{\partial f_9}{\partial \psi} \big|_{\theta_i, \phi_i, \psi_i} \end{bmatrix} \begin{bmatrix} d\theta \\ d\phi \\ d\psi \end{bmatrix} = d\mathbf{f}. \quad (36)$$

Using NONLINEAR LEAST SQUARES FITTING then gives solutions which converge to  $(\theta, \phi, \psi)$ .

## Euler-Bernoulli Triangle

see SEIDEL-ENTRINGER-ARNOLD TRIANGLE

## Euler Brick

A RECTANGULAR PARALLELEPIPED ("BRICK") with integral edges  $a > b > c$  and face diagonals  $d_{ij}$  given by

$$d_{ab} = \sqrt{a^2 + b^2} \quad (1)$$

$$d_{ac} = \sqrt{a^2 + c^2} \quad (2)$$

$$d_{bc} = \sqrt{b^2 + c^2}. \quad (3)$$

The problem is also called the BRICK, DIAGONALS PROBLEM, PERFECT BOX, PERFECT CUBOID, or RATIONAL CUBOID problem.

Euler found the smallest solution, which has sides  $a = 240$ ,  $b = 117$ , and  $c = 44$  and face DIAGONALS  $d_{ab} = 267$ ,  $d_{ac} = 244$ , and  $d_{bc} = 125$ . Kraitchik gave 257 cuboids with the ODD edge less than 1 million (Guy 1994, p. 174). F. Helenius has compiled a list of the 5003 smallest (measured by the longest edge) Euler bricks. The first few are (240, 117, 44), (275, 252, 240), (693, 480, 140), (720, 132, 85), (792, 231, 160), ... (Sloane's A031173, A031174, and A031175). Parametric solutions for Euler bricks are also known.

No solution is known in which the oblique SPACE DIAGONAL

$$d_{abc} = \sqrt{a^2 + b^2 + c^2} \quad (4)$$

is also an INTEGER. If such a brick exists, the smallest side must be at least 1,281,000,000 (R. Rathbun 1996). Such a solution is equivalent to solving the DIOPHANTINE EQUATIONS

$$A^2 + B^2 = C^2 \quad (5)$$

$$A^2 + D^2 = E^2 \quad (6)$$

$$B^2 + D^2 = F^2 \quad (7)$$

$$B^2 + E^2 = G^2. \quad (8)$$

A solution with integral SPACE DIAGONAL and two out of three face diagonals is  $a = 672$ ,  $b = 153$ , and  $c = 104$ , giving  $d_{ab} = 3\sqrt{52777}$ ,  $d_{ac} = 680$ ,  $d_{bc} = 185$ , and  $d_{abc} = 697$ . A solution giving integral space and face diagonals with only a single nonintegral EDGE is  $a = 18720$ ,  $b = \sqrt{211773121}$ , and  $c = 7800$ , giving  $d_{ab} = 23711$ ,  $d_{ac} = 20280$ ,  $d_{bc} = 16511$ , and  $d_{abc} = 24961$ .

## Euler Chain

A CHAIN (GRAPH) whose EDGES consist of all graph EDGES.

## Euler Characteristic

Let a closed surface have GENUS  $g$ . Then the POLYHEDRAL FORMULA becomes the POINCARÉ FORMULA

$$\chi \equiv V - E + F = 2 - 2g, \quad (1)$$

where  $\chi$  is the Euler characteristic, sometimes also known as the EULER-POINCARÉ CHARACTERISTIC. In terms of the INTEGRAL CURVATURE of the surface  $K$ ,

$$\iint K da = 2\pi\chi. \quad (2)$$

The Euler characteristic is sometimes also called the EULER NUMBER. It can also be expressed as

$$\chi = p_0 - p_1 + p_2, \quad (3)$$

where  $p_i$  is the  $i$ th BETTI NUMBER of the space.  
 see also CHROMATIC NUMBER, MAP COLORING

## Euler's Circle

see NINE-POINT CIRCLE

**Euler's Conjecture**

$$g(k) = 2^k + \left\lfloor \left(\frac{3}{2}\right)^k \right\rfloor - 2,$$

where  $g(k)$  is the quantity appearing in WARING'S PROBLEM, and  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

see also WARING'S PROBLEM

**Euler Constant**

see  $e$ , EULER-MASCHERONI CONSTANT, MACLAURIN-CAUCHY THEOREM

**Euler's Criterion**

Let  $p = 2m + 1$  be an ODD PRIME and  $a$  a POSITIVE INTEGER with  $p \nmid a$ . Then

$$a^m \equiv 1 \pmod{p} \quad (1)$$

IFF there exists an INTEGER  $t$  such that

$$p \equiv t^2 \pmod{p}. \quad (2)$$

In other words,

$$a^{(p-1)/2} \equiv \frac{a}{p} \pmod{p}, \quad (3)$$

where  $(a/p)$  is the LEGENDRE SYMBOL.

see also QUADRATIC RESIDUE

Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, pp. 33-37, 1993.  
Wagon, S. *Mathematica in Action*. New York: W. H. Freeman, p. 293, 1991.

**Euler Curvature Formula**

$$\kappa = \kappa_1 \cos^2 \theta + \kappa_2 \sin^2 \theta,$$

where  $\kappa$  is the normal CURVATURE in a direction making an ANGLE  $\theta$  with the first principle direction.

**Euler Differential Equation**

The general nonhomogeneous equation is

$$x^2 \frac{d^2 y}{dx^2} + \alpha x \frac{dy}{dx} + \beta y = S(x). \quad (1)$$

The homogeneous equation is

$$x^2 y'' + \alpha x y' + \beta y = 0 \quad (2)$$

$$y'' + \frac{\alpha}{x} y' + \frac{\beta}{x^2} y = 0. \quad (3)$$

Now attempt to convert the equation from

$$y'' + p(x)y' + q(x)y = 0 \quad (4)$$

to one with constant COEFFICIENTS

$$\frac{d^2 y}{dz^2} + A \frac{dy}{dz} + B y = 0 \quad (5)$$

by using the standard transformation for linear SECOND-ORDER ORDINARY DIFFERENTIAL EQUATIONS. Comparing (3) and (5), the functions  $p(x)$  and  $q(x)$  are

$$p(x) \equiv \frac{\alpha}{x} = \alpha x^{-1} \quad (6)$$

$$q(x) \equiv \frac{\beta}{x^2} = \beta x^{-2}. \quad (7)$$

Let  $B \equiv \beta$  and define

$$\begin{aligned} z &\equiv B^{-1/2} \int \sqrt{q(x)} dx = \beta^{-1/2} \int \sqrt{\beta x^{-2}} dx \\ &= \int x^{-1} dx = \ln x. \end{aligned} \quad (8)$$

Then  $A$  is given by

$$\begin{aligned} A &\equiv \frac{q'(x) + 2p(x)q(x)}{2[q(x)]^{3/2}} B^{1/2} \\ &= \frac{-2\beta x^{-3} + 2(\alpha x^{-1})(\beta x^{-2})}{2(\beta x^{-2})^{3/2}} \beta^{1/2} \\ &= \alpha - 1, \end{aligned} \quad (9)$$

which is a constant. Therefore, the equation becomes a second-order ODE with constant COEFFICIENTS

$$\frac{d^2 y}{dz^2} + (\alpha - 1) \frac{dy}{dz} + \beta y = 0. \quad (10)$$

Define

$$\begin{aligned} r_1 &\equiv \frac{1}{2} \left( -A + \sqrt{A^2 - 4B} \right) \\ &= \frac{1}{2} \left[ 1 - \alpha + \sqrt{(\alpha - 1)^2 - 4\beta} \right] \end{aligned} \quad (11)$$

$$\begin{aligned} r_2 &\equiv \frac{1}{2} \left( -A - \sqrt{A^2 - 4B} \right) \\ &= \frac{1}{2} \left[ 1 - \alpha - \sqrt{(\alpha - 1)^2 - 4\beta} \right] \end{aligned} \quad (12)$$

and

$$a \equiv \frac{1}{2}(1 - \alpha) \quad (13)$$

$$b \equiv \frac{1}{2} \sqrt{4\beta - (\alpha - 1)^2}. \quad (14)$$

The solutions are

$$y = \begin{cases} c_1 e^{r_1 z} + c_2 e^{r_2 z} & (\alpha - 1)^2 > 4\beta \\ (c_1 + c_2 z) e^{a z} & (\alpha - 1)^2 = 4\beta \\ e^{a z} [c_1 \cos(bz) + c_2 \sin(bz)] & (\alpha - 1)^2 < 4\beta. \end{cases} \quad (15)$$

In terms of the original variable  $x$ ,

$$y = \begin{cases} c_1 |x|^{r_1} + c_2 |x|^{r_2} & (\alpha - 1)^2 > 4\beta \\ (c_1 + c_2 \ln |x|) |x|^a & (\alpha - 1)^2 = 4\beta \\ |x|^a [c_1 \cos(b \ln |x|) + c_2 \sin(b \ln |x|)] & (\alpha - 1)^2 < 4\beta. \end{cases} \quad (16)$$

**Euler's Displacement Theorem**

The general displacement of a rigid body (or coordinate frame) with one point fixed is a ROTATION about some axis. Furthermore, a ROTATION may be described in any basis using three ANGLES.

see also EUCLIDEAN MOTION, EULER ANGLES, RIGID MOTION, ROTATION

**Euler's Distribution Theorem**

For signed distances,

$$\overline{AB} \cdot \overline{CD} + \overline{AC} \cdot \overline{DB} + \overline{AD} \cdot \overline{BC} = 0,$$

since

$$(b-a)(d-c) + (c-a)(b-d) + (d-a)(c-b) = 0.$$

**Euler Equation**

see also EULER DIFFERENTIAL EQUATION, EULER FORMULA, EULER-LAGRANGE DIFFERENTIAL EQUATION

**Euler's Factorization Method**

Works by expressing  $N$  as a QUADRATIC FORM in two different ways. Then

$$N = a^2 + b^2 = c^2 + d^2, \quad (1)$$

so

$$a^2 - c^2 = d^2 - b^2 \quad (2)$$

$$(a-c)(a+c) = (d-b)(d+b). \quad (3)$$

Let  $k$  be the GREATEST COMMON DIVISOR of  $a-c$  and  $d-b$  so

$$a-c = kl \quad (4)$$

$$d-b = km \quad (5)$$

$$(l, m) = 1, \quad (6)$$

(where  $(l, m)$  denotes the GREATEST COMMON DIVISOR of  $l$  and  $m$ ), and

$$l(a+c) = m(d+b). \quad (7)$$

But since  $(l, m) = 1$ ,  $m|a+c$  and

$$a+c = mn, \quad (8)$$

which gives

$$b+d = ln, \quad (9)$$

so we have

$$\begin{aligned} \left[\left(\frac{1}{2}k\right)^2 + \left(\frac{1}{2}n\right)^2\right](l^2 + m^2) &= \frac{1}{4}(k^2 + n^2)(l^2 + m^2) \\ &= \frac{1}{4}[(kn)^2 + (kl)^2 + (nm)^2 + (nl)^2] \\ &= \frac{1}{4}[(d-b)^2 + (a-c)^2 + (a+c)^2 + (d+b)^2] \\ &= \frac{1}{4}(2a^2 + 2b^2 + 2c^2 + 2d^2) \\ &= \frac{1}{4}(2N + 2N) = N. \end{aligned} \quad (10)$$

see also PRIME FACTORIZATION ALGORITHMS

**Euler's Finite Difference Transformation**

A transformation for the acceleration of the convergence of slowly converging ALTERNATING SERIES,

$$\sum_{k=0}^{\infty} (-1)^k a_k = \sum_{n=0}^{\infty} \frac{\Delta^n a_0}{2^{n+1}}.$$

**Euler Formula**

The Euler formula states

$$e^{ix} = \cos x + i \sin x, \quad (1)$$

where  $i$  is the IMAGINARY NUMBER. Note that the EULER POLYHEDRAL FORMULA is sometimes also called the Euler formula, as is the EULER CURVATURE FORMULA. The equivalent expression

$$ix = \ln(\cos x + i \sin x) \quad (2)$$

had previously been published by Cotes (1714). The special case of the formula with  $x = \pi$  gives the beautiful identity

$$e^{i\pi} + 1 = 0, \quad (3)$$

an equation connecting the fundamental numbers  $i$ ,  $\pi$ ,  $e$ , 1, and 0 (ZERO).

The Euler formula can be demonstrated using a series expansion

$$\begin{aligned} e^{ix} &= \sum_{n=0}^{\infty} \frac{(ix)^n}{n!} \\ &= \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n}}{(2n)!} + i \sum_{n=1}^{\infty} \frac{(-1)^{n-1} x^{2n-1}}{(2n-1)!} \\ &= \cos x + i \sin x. \end{aligned} \quad (4)$$

It can also be proven using a COMPLEX integral. Let

$$z \equiv \cos \theta + i \sin \theta \quad (5)$$

$$dz = (-\sin \theta + i \cos \theta) d\theta = i(\cos \theta + i \sin \theta) d\theta = iz d\theta \quad (6)$$

$$\int \frac{dz}{z} = \int i d\theta \quad (7)$$

$$\ln z = i\theta, \quad (8)$$

so

$$z = e^{i\theta} \equiv \cos \theta + i \sin \theta. \quad (9)$$

## Euler Four-Square Identity

The amazing polynomial identity

$$\begin{aligned} (a_1^2 + a_2^2 + a_3^2 + a_4^2)(b_1^2 + b_2^2 + b_3^2 + b_4^2) \\ = (a_1b_1 - a_2b_2 - a_3b_3 - a_4b_4)^2 \\ + (a_1b_2 + a_2b_1 + a_3b_4 - a_4b_3)^2 \\ + (a_1b_3 - a_2b_4 + a_3b_1 + a_4b_2)^2 \\ + (a_1b_4 + a_2b_3 - a_3b_2 + a_4b_1)^2, \end{aligned}$$

communicated by Euler in a letter to Goldbach on April 15, 1705. The identity also follows from the fact that the norm of the product of two QUATERNIONS is the product of the norms (Conway and Guy 1996).

## Euler's Graeco-Roman Squares Conjecture

Euler conjectured that there do not exist GRAECO-ROMAN SQUARES (now known as EULER SQUARES) of order  $n = 4k + 2$  for  $k = 1, 2, \dots$ . Such squares were found to exist in 1959, refuting the CONJECTURE.

see also EULER SQUARE, LATIN SQUARE

## Euler Graph

A GRAPH containing an EULERIAN CIRCUIT. An undirected GRAPH is Eulerian IFF every VERTEX has EVEN DEGREE. A DIRECTED GRAPH is Eulerian IFF every VERTEX has equal INDEGREE and OUTDEGREE. A planar BIPARTITE GRAPH is DUAL to a planar Euler graph and vice versa. The number of Euler graphs with  $n$  nodes are 1, 1, 2, 3, 7, 16, 54, 243, ... (Sloane's A002854).

## Euler's Homogeneous Function Theorem

Let  $f(x, y)$  be a HOMOGENEOUS FUNCTION of order  $n$  so that

$$f(tx, ty) = t^n f(x, y). \quad (1)$$

Then define  $x' \equiv xt$  and  $y' \equiv yt$ . Then

$$\begin{aligned} nt^{n-1}f(x, y) &= \frac{\partial f}{\partial x'} \frac{\partial x'}{\partial t} + \frac{\partial f}{\partial y'} \frac{\partial y'}{\partial t} \\ &= x \frac{\partial f}{\partial x'} + y \frac{\partial f}{\partial y'} = x \frac{\partial f}{\partial (xt)} + y \frac{\partial f}{\partial (yt)}. \quad (2) \end{aligned}$$

Let  $t = 1$ , then

$$x \frac{\partial f}{\partial x} + y \frac{\partial f}{\partial y} = nf(x, y). \quad (3)$$

This can be generalized to an arbitrary number of variables

$$x_i \frac{\partial f}{\partial x_i} = nf(\mathbf{x}), \quad (4)$$

where EINSTEIN SUMMATION has been used.

## Euler's Hypergeometric Transformations

$${}_2F_1(a, b; c; z) = \int_0^1 \frac{t^{b-1}(1-t)^{c-b-1}}{(1-tz)^a} dt, \quad (1)$$

where  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION. The solution can be written using the Euler's transformations

$$t \rightarrow t \quad (2)$$

$$t \rightarrow 1 - t \quad (3)$$

$$t \rightarrow (1 - z - tz)^{-1} \quad (4)$$

$$t \rightarrow \frac{1-t}{1-tz} \quad (5)$$

in the equivalent forms

$${}_2F_1(a, b; c; z) = (1-z)^{-a} {}_2F_1(a, c-b; c; z/(z-1)) \quad (6)$$

$$= (1-z)^{-b} {}_2F_1(c-a, b; c; z/(z-1)) \quad (7)$$

$$= (1-z)^{c-a-b} {}_2F_1(c-a, c-b; c; z). \quad (8)$$

see also HYPERGEOMETRIC FUNCTION

## Euler Identity

For  $|z| < 1$ ,

$$\prod_{p=1}^{\infty} (1 + z^p) = \prod_{q=1}^{\infty} (1 - z^{2q-1})^{-1}.$$

see also JACOBI TRIPLE PRODUCT,  $q$ -SERIES

**Euler's Idoneal Number**

see IDONEAL NUMBER

**Euler Integral**

Euler integration was defined by Schanuel and subsequently explored by Rota, Chen, and Klain. The Euler integral of a FUNCTION  $f : \mathbb{R} \rightarrow \mathbb{R}$  (assumed to be piecewise-constant with finitely many discontinuities) is the sum of

$$f(x) - \frac{1}{2}[f(x_+) + f(x_-)]$$

over the finitely many discontinuities of  $f$ . The  $n$ -D Euler integral can be defined for classes of functions  $\mathbb{R}^n \rightarrow \mathbb{R}$ . Euler integration is additive, so the Euler integral of  $f + g$  equals the sum of the Euler integrals of  $f$  and  $g$ .

see also EULER MEASURE

**Euler-Jacobi Pseudoprime**

An Euler-Jacobi pseudoprime is a number  $n$  such that

$$2^{(n-1)/2} \equiv \frac{2}{n} \pmod{n}.$$

The first few are 561, 1105, 1729, 1905, 2047, 2465, ... (Sloane's A006971).

see also PSEUDOPRIME

**Euler L-Function**

A special case of the ARTIN  $L$ -FUNCTION for the POLYNOMIAL  $x^2 + 1$ . It is given by

$$L(s) = \prod_{p \text{ odd prime}} \frac{1}{1 - \chi^-(p)p^{-s}},$$

where

$$\begin{aligned} \chi^-(p) &\equiv \begin{cases} 1 & \text{for } p \equiv 1 \pmod{4} \\ -1 & \text{for } p \equiv 3 \pmod{4} \end{cases} \\ &= \left( \frac{-1}{p} \right), \end{aligned}$$

where  $(-1/p)$  is a LEGENDRE SYMBOL.

**References**

Knapp, A. W. "Group Representations and Harmonic Analysis, Part II." *Not. Amer. Math. Soc.* **43**, 537-549, 1996.

**Euler-Lagrange Differential Equation**

A fundamental equation of CALCULUS OF VARIATIONS which states that if  $J$  is defined by an INTEGRAL of the form

$$J = \int f(x, y, \dot{y}) dx, \quad (1)$$

where

$$\dot{y} \equiv \frac{dy}{dt}, \quad (2)$$

then  $J$  has a STATIONARY VALUE if the Euler-Lagrange differential equation

$$\frac{\partial f}{\partial y} - \frac{d}{dt} \left( \frac{\partial f}{\partial \dot{y}} \right) = 0 \quad (3)$$

is satisfied. If time DERIVATIVE NOTATION is replaced instead by space variable notation, the equation becomes

$$\frac{\partial f}{\partial y} - \frac{d}{dx} \frac{\partial f}{\partial y_x} = 0. \quad (4)$$

In many physical problems,  $f_x$  (the PARTIAL DERIVATIVE of  $f$  with respect to  $x$ ) turns out to be 0, in which case a manipulation of the Euler-Lagrange differential equation reduces to the greatly simplified and partially integrated form known as the BELTRAMI IDENTITY,

$$f - y_x \frac{\partial f}{\partial y_x} = C. \quad (5)$$

For three independent variables (Arfken 1985, pp. 924-944), the equation generalizes to

$$\frac{\partial f}{\partial u} - \frac{\partial}{\partial x} \frac{\partial f}{\partial u_x} - \frac{\partial}{\partial y} \frac{\partial f}{\partial u_y} - \frac{\partial}{\partial z} \frac{\partial f}{\partial u_z} = 0. \quad (6)$$

Problems in the CALCULUS OF VARIATIONS often can be solved by solution of the appropriate Euler-Lagrange equation.

To derive the Euler-Lagrange differential equation, examine

$$\begin{aligned} \delta J &\equiv \delta \int L(q, \dot{q}, t) dt = \int \left( \frac{\partial L}{\partial q} \delta q + \frac{\partial L}{\partial \dot{q}} \delta \dot{q} \right) dt \\ &= \int \left[ \frac{\partial L}{\partial q} \delta q + \frac{\partial L}{\partial \dot{q}} \frac{d(\delta q)}{dt} \right] dt, \end{aligned} \quad (7)$$

since  $\delta \dot{q} = d(\delta q)/dt$ . Now, integrate the second term by PARTS using

$$u = \frac{\partial L}{\partial \dot{q}} \quad dv = d(\delta q) \quad (8)$$

$$du = \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}} \right) dt \quad v = \delta q, \quad (9)$$

so

$$\int \frac{\partial L}{\partial \dot{q}} \frac{d(\delta q)}{dt} dt = \int \frac{\partial L}{\partial \dot{q}} d(\delta q) \\ = \left[ \frac{\partial L}{\partial \dot{q}} \delta q \right]_{t_1}^{t_2} - \int_{t_1}^{t_2} \left( \frac{d}{dt} \frac{\partial L}{\partial \dot{q}} \right) \delta q dt. \quad (10)$$

Combining (7) and (10) then gives

$$\delta J = \left[ \frac{\partial L}{\partial \dot{q}} \delta q \right]_{t_1}^{t_2} + \int_{t_1}^{t_2} \left( \frac{\partial L}{\partial q} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}} \right) \delta q dt. \quad (11)$$

But we are varying the path only, not the endpoints, so  $\delta q(t_1) = \delta q(t_2) = 0$  and (11) becomes

$$\delta J = \int_{t_1}^{t_2} \left( \frac{\partial L}{\partial q} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}} \right) \delta q dt. \quad (12)$$

We are finding the STATIONARY VALUES such that  $\delta J = 0$ . These must vanish for any small change  $\delta q$ , which gives from (12),

$$\frac{\partial L}{\partial q} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}} \right) = 0. \quad (13)$$

This is the Euler-Lagrange differential equation.

The variation in  $J$  can also be written in terms of the parameter  $\kappa$  as

$$\delta J = \int [f(x, y + \kappa v, \dot{y} + \kappa \dot{v}) - f(x, y, \dot{y})] dt \\ = \kappa I_1 + \frac{1}{2} \kappa^2 I_2 + \frac{1}{6} \kappa^3 I_3 + \frac{1}{24} \kappa^4 I_4 + \dots, \quad (14)$$

where

$$v = \delta y \quad (15)$$

$$\dot{v} = \delta \dot{y} \quad (16)$$

and the first, second, etc., variations are

$$I_1 = \int (v f_y + \dot{v} f_{\dot{y}}) dt \quad (17)$$

$$I_2 = \int (v^2 f_{yy} + 2v\dot{v} f_{y\dot{y}} + \dot{v}^2 f_{\dot{y}\dot{y}}) dt \quad (18)$$

$$I_3 = \int (v^3 f_{yyy} + 3v^2\dot{v} f_{yy\dot{y}} + 3v\dot{v}^2 f_{y\dot{y}\dot{y}} + \dot{v}^3 f_{\dot{y}\dot{y}\dot{y}}) dt \quad (19)$$

$$I_4 = \int (v^4 f_{yyyy} + 4v^3\dot{v} f_{yyy\dot{y}} + 6v^2\dot{v}^2 f_{yy\dot{y}\dot{y}} \\ + 4v\dot{v}^3 f_{y\dot{y}\dot{y}\dot{y}} + \dot{v}^4 f_{\dot{y}\dot{y}\dot{y}\dot{y}}) dt. \quad (20)$$

The second variation can be re-expressed using

$$\frac{d}{dt} (v^2 \dot{\lambda}) = v^2 \ddot{\lambda} + 2v\dot{v}\dot{\lambda}, \quad (21)$$

so

$$I_2 + [v^2 \dot{\lambda}]_1^2 = \int_1^2 [v^2 (f_{yy} + \dot{\lambda}) + 2v\dot{v} (f_{y\dot{y}} + \lambda) + \dot{v}^2 f_{\dot{y}\dot{y}}] dt. \quad (22)$$

But

$$[v^2 \dot{\lambda}]_2^1 = 0. \quad (23)$$

Now choose  $\lambda$  such that

$$f_{y\dot{y}} (f_{yy} + \dot{\lambda}) = (f_{yy} + \lambda)^2 \quad (24)$$

and  $z$  such that

$$f_{yy} + \lambda = -\frac{f_{y\dot{y}}}{z} \frac{dz}{dt} \quad (25)$$

so that  $z$  satisfies

$$f_{y\dot{y}} \ddot{z} + \dot{f}_{y\dot{y}} \dot{z} - (f_{yy} - \dot{f}_{y\dot{y}}) z = 0. \quad (26)$$

It then follows that

$$I_2 = \int f_{y\dot{y}} \left( \dot{v} + \frac{f_{y\dot{y}} + \lambda}{f_{y\dot{y}} v} \right)^2 dt = \int f_{y\dot{y}} \left( \dot{v} - \frac{v}{z} \frac{dz}{dt} \right)^2 dt. \quad (27)$$

#### Euler-Lagrange Derivative

The derivative

$$\frac{\delta L}{\delta q} \equiv \frac{\partial L}{\partial q} - \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}} \right)$$

appearing in the EULER-LAGRANGE DIFFERENTIAL EQUATION.

#### Euler Line

The line on which the ORTHOCENTER  $H$ , CENTROID  $M$ , CIRCUMCENTER  $O$ , DE LONGCHAMPS POINT  $L$ , NINE-POINT CENTER  $F$ , and the TANGENTIAL TRIANGLE CIRCUMCIRCLE  $O_T$  of a TRIANGLE lie. The INCENTER lies on the Euler line only if the TRIANGLE is an ISOSCELES TRIANGLE. The Euler line consists of all points with TRILINEAR COORDINATES  $\alpha : \beta : \gamma$  which satisfy

$$\begin{vmatrix} \alpha & \beta & \gamma \\ \cos A & \cos B & \cos C \\ \cos B \cos C & \cos C \cos A & \cos A \cos B \end{vmatrix} = 0, \quad (1)$$

which simplifies to

$$\alpha \cos A (\cos^2 B - \cos^2 C) + \beta \cos B (\cos^2 C - \cos^2 A) + \gamma \cos C (\cos^2 A - \cos^2 B) = 0. \quad (2)$$

This can also be written

$$\alpha \sin(2A) \sin(B - C) + \beta \sin(2B) \sin(C - A) + \gamma \sin(2C) \sin(A - B) = 0. \quad (3)$$

The Euler line may also be given parametrically by

$$P(\lambda) = O + \lambda H \quad (4)$$

(Oldknow 1996).

$\lambda$	Center
-2	point at infinity
-1	de Longchamps point $L$
0	circumcenter $O$
1	centroid $G$
2	nine-point center $F$
$\infty$	orthocenter $H$

The ORTHOCENTER is twice as far from the CENTROID as is the CIRCUMCENTER. The CIRCUMCENTER  $O$ , NINE-POINT CENTER  $F$ , CENTROID  $G$ , and ORTHOCENTER  $H$  form a HARMONIC RANGE.

The Euler line intersects the SODDY LINE in the DE LONGCHAMPS POINT, and the GERGONNE LINE in the EVANS POINT. The ISOTOMIC CONJUGATE of the Euler line is called JERABEK'S HYPERBOLA (Casey 1893, Vandeghen 1965).

see also CENTROID (TRIANGLE), CIRCUMCENTER, EVANS POINT, GERGONNE LINE, JERABEK'S HYPERBOLA, DE LONGCHAMPS POINT, NINE-POINT CENTER, ORTHOCENTER, SODDY LINE, TANGENTIAL TRIANGLE

#### Euler-Lucas Pseudoprime

Let  $U(P, Q)$  and  $V(P, Q)$  be LUCAS SEQUENCES generated by  $P$  and  $Q$ , and define

$$D \equiv P^2 - 4Q.$$

Then

$$\begin{cases} U_{(n-(D/n))/2} \equiv 0 \pmod{n} & \text{when } (Q/n) = 1 \\ V_{(n-(D/n))/2} \equiv D \pmod{n} & \text{when } (Q/n) = -1, \end{cases}$$

where  $(Q/n)$  is the LEGENDRE SYMBOL. An ODD COMPOSITE NUMBER  $n$  such that  $(n, QD) = 1$  (i.e.,  $n$  and  $QD$  are RELATIVELY PRIME) is called an Euler-Lucas pseudoprime with parameters  $(P, Q)$ .

see also PSEUDOPRIME, STRONG LUCAS PSEUDOPRIME

#### References

- Ribenboim, P. "Euler-Lucas Pseudoprimes (elpsp( $P, Q$ )) and Strong Lucas Pseudoprimes (slspsp( $P, Q$ ))." §2.X.C in *The New Book of Prime Number Records*. New York: Springer-Verlag, pp. 130–131, 1996.

#### Euler's Machin-Like Formula

The MACHIN-LIKE FORMULA

$$\frac{1}{4}\pi = \tan^{-1}\left(\frac{1}{2}\right) + \tan^{-1}\left(\frac{1}{3}\right).$$

The other 2-term MACHIN-LIKE FORMULAS are HERMANN'S FORMULA, HUTTON'S FORMULA, and MACHIN'S FORMULA.

see also INVERSE TANGENT

#### Euler-Maclaurin Integration Formulas

The first Euler-Maclaurin integration formula is

$$\begin{aligned} \int_0^1 f(x) dx &= \frac{1}{2}[f(1) + f(0)] \\ &- \sum_{p=1}^q \frac{1}{(2p)!} B_{2p} [f^{(2p-1)}(1) - f^{(2p-1)}(0)] \\ &+ \frac{1}{(2q)!} \int_0^1 f^{(2q)}(x) B_{2q}(x) dx, \quad (1) \end{aligned}$$

where  $B_n$  are BERNOULLI NUMBERS. SUMS may be converted to INTEGRALS by inverting the FORMULA to obtain

$$\begin{aligned} \sum_{m=1}^n f(m) &= \int_1^n f(x) dx + \frac{1}{2}[f(1) + f(n)] \\ &+ \frac{B_2}{2!} [f'(n) - f'(1)] + \dots \quad (2) \end{aligned}$$

For a more general case when  $f(x)$  is tabulated at  $n$  values  $f_1, f_2, \dots, f_n$ ,

$$\int_{x_1}^{x_n} f(x) dx = h[\tfrac{1}{2}f_1 + f_2 + f_3 + \dots + f_{n-1} + \tfrac{1}{2}f_n] - \sum_{k=1}^{\infty} \frac{B_{2k} h^{2k}}{(2k)!} [f_n^{(2k-1)} - f_1^{(2k-1)}]. \quad (3)$$

The Euler-Maclaurin formula is implemented in *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) as the function `NSum` with option `Method->Integrate`.

The second Euler-Maclaurin integration formula is used when  $f(x)$  is tabulated at  $n$  values  $f_{3/2}, f_{5/2}, \dots, f_{n-1/2}$ :

$$\int_{x_1}^{x_n} f(x) dx = h[f_{3/2} + f_{5/2} + f_{7/2} + \dots + f_{n-3/2} + f_{n-1/2}] - \sum_{k=1}^{\infty} \frac{B_{2k} h^{2k}}{(2k)!} (1 - 2^{-2k+1}) [f_n^{(2k-1)} - f_1^{(2k-1)}]. \quad (4)$$

#### Euler-Mascheroni Constant

The Euler-Mascheroni constant is denoted  $\gamma$  (or sometimes  $C$ ) and has the numerical value

$$\gamma \approx 0.577215664901532860606512090082402431042 \dots \quad (1)$$

(Sloane's A001620). The CONTINUED FRACTION of the Euler-Mascheroni constant is  $[0, 1, 1, 2, 1, 2, 1, 4, 3, 13, 5, 1, 1, 8, 1, 2, 4, 1, 1, 40, \dots]$  (Sloane's A002852). The first few CONVERGENTS are  $1, 1/2, 3/5, 4/7, 11/19, 15/26, 71/123, 228/395, 3035/5258, 15403/26685, \dots$  (Sloane's A046114 and A046115). The positions at which the digits 1, 2, ... first occur in the CONTINUED FRACTION are 2, 4, 9, 8, 11, 69, 24, 14, 139, 52, 22, ... (Sloane's A033149). The sequence of largest terms in the CONTINUED FRACTION is 1, 2, 4, 13, 40, 49, 65, 399, 2076, ... (Sloane's A033091), which occur at positions 2, 4, 8, 10, 20, 31, 34, 40, 529, ... (Sloane's A033092).

It is not known if this constant is IRRATIONAL, let alone TRANSCENDENTAL. However, Conway and Guy (1996) are "prepared to bet that it is transcendental," although they do not expect a proof to be achieved within their lifetimes.

The Euler-Mascheroni constant arises in many integrals

$$\gamma \equiv - \int_0^{\infty} e^{-x} \ln x \, dx \quad (2)$$

$$= \int_0^{\infty} \left( \frac{1}{1-e^{-x}} - \frac{1}{x} \right) e^{-x} \, dx \quad (3)$$

$$= \int_0^{\infty} \frac{1}{x} \left( \frac{1}{1+x} - e^{-x} \right) \, dx. \quad (4)$$

and sums

$$\gamma \equiv 1 + \sum_{k=2}^{\infty} \left[ \frac{1}{k} + \ln \left( \frac{k-1}{k} \right) \right] \quad (5)$$

$$= \lim_{m \rightarrow \infty} \left( \sum_{n=1}^m \frac{1}{n} - \ln m \right) \quad (6)$$

$$= \sum_{n=2}^{\infty} (-1)^n \frac{\zeta(n)}{n} \quad (7)$$

$$= \ln \left( \frac{4}{\pi} \right) - \sum_{n=1}^{\infty} \frac{(-1)^n \zeta(n+1)}{2^n (n+1)} \quad (8)$$

$$= \lim_{n \rightarrow \infty} \left[ \sum_{k=1}^n k^{-1} - \ln n - \frac{1}{2n} + \sum_{k=1}^n \frac{B_{2k}}{(2k)n^{2k}} \right], \quad (9)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION and  $B_n$  are the BERNOULLI NUMBERS. It is also given by the EULER PRODUCT

$$e^{\gamma} = \lim_{n \rightarrow \infty} \frac{1}{\ln n} \prod_{i=1}^n \frac{1}{1 - \frac{1}{p_i}}, \quad (10)$$

where the product is over PRIMES  $p$ . Another connection with the PRIMES was provided by Dirichlet's 1838 proof that the average number of DIVISORS of all numbers from 1 to  $n$  is asymptotic to

$$\frac{\sum_{i=1}^n \sigma_0(i)}{n} \sim \ln n + 2\gamma - 1 \quad (11)$$

(Conway and Guy 1996). de la Vallée Poussin (1898) proved that, if a large number  $n$  is divided by all PRIMES  $\leq n$ , then the average amount by which the QUOTIENT is less than the next whole number is  $\gamma$ .

INFINITE PRODUCTS involving  $\gamma$  also arise from the  $G$ -FUNCTION with POSITIVE INTEGER  $n$ . The cases  $G(2)$  and  $G(3)$  give

$$\prod_{n=1}^{\infty} e^{-1+1/(2n)} \left(1 + \frac{1}{n}\right)^n = \frac{e^{1+\gamma/2}}{\sqrt{2\pi}} \quad (12)$$

$$\prod_{n=1}^{\infty} e^{-2+2/n} \left(1 + \frac{2}{n}\right)^n = \frac{e^{3+2\gamma}}{2\pi}. \quad (13)$$

The Euler-Mascheroni constant is also given by the limits

$$\gamma = \lim_{s \rightarrow 1} \frac{\zeta(s) - 1}{s - 1} \quad (14)$$

$$= -\Gamma'(1) \quad (15)$$

$$= \lim_{x \rightarrow \infty} \left[ x - \Gamma\left(\frac{1}{x}\right) \right] \quad (16)$$

(Le Lionnais 1983).

The difference between the  $n$ th convergent in (6) and  $\gamma$  is given by

$$\sum_{k=1}^n \frac{1}{k} - \ln n - \gamma = \int_n^{\infty} \frac{x - [x]}{x^2} dx, \quad (17)$$

where  $[x]$  is the FLOOR FUNCTION, and satisfies the INEQUALITY

$$\frac{1}{2(n+1)} < \sum_{k=1}^n \frac{1}{k} - \ln n - \gamma < \frac{1}{2n} \quad (18)$$

(Young 1991). A series with accelerated convergence is

$$\gamma = \frac{3}{2} - \ln 2 - \sum_{m=2}^{\infty} (-1)^m \frac{m-1}{m} [\zeta(m) - 1] \quad (19)$$

(Flajolet and Vardi 1996). Another series is

$$\gamma = \sum_{n=1}^{\infty} (-1)^n \frac{[\lg n]}{n} \quad (20)$$

(Vacca 1910, Gerst 1969), where LG is the LOGARITHM to base 2. The convergence of this series can be greatly improved using Euler's CONVERGENCE IMPROVEMENT transformation to

$$\gamma = \sum_{k=1}^{\infty} 2^{-(k+1)} \sum_{j=0}^{k-1} \frac{1}{\binom{2^{k-j}+j}{j}}, \quad (21)$$

where  $\binom{a}{i}$  is a BINOMIAL COEFFICIENT (Beeler *et al.* 1972, Item 120, with  $k-j$  replacing the undefined  $i$ ). Bailey (1988) gives

$$\gamma = \frac{2^n}{e^{2^n}} \sum_{m=0}^{\infty} \frac{2^{mn}}{(m+1)!} \sum_{t=0}^m \frac{1}{t+1} - n \ln 2 + \mathcal{O}\left(\frac{1}{2^n e^{2^n}}\right), \quad (22)$$

which is an improvement over Sweeney (1963).

The symbol  $\gamma$  is sometimes also used for

$$\gamma' \equiv e^{\gamma} \approx 1.781072 \quad (23)$$

(Gradshteyn and Ryzhik 1979, p. xxvii).

Odena (1982–1983) gave the strange approximation

$$(0.11111111)^{1/4} = 0.577350\dots, \quad (24)$$

and Castellanos (1988) gave

$$\left(\frac{7}{83}\right)^{2/9} = 0.57721521\dots \quad (25)$$

$$\left(\frac{520^6 + 22}{52^4}\right)^{1/6} = 0.5772156634\dots \quad (26)$$

$$\left(\frac{80^3 + 92}{61^4}\right)^{1/6} = 0.57721566457\dots \quad (27)$$

$$\frac{990^3 - 55^3 - 79^2 - 4^2}{70^5} = 0.5772156649015295\dots \quad (28)$$

No quadratically converging algorithm for computing  $\gamma$  is known (Bailey 1988). 7,000,000 digits of  $\gamma$  have been computed as of Feb. 1998 (Plouffe).

## Euler-Mascheroni Integrals

Define

$$I_n \equiv (-1)^n \int_0^\infty (\ln z)^n e^{-z} dz, \quad (1)$$

then

$$I_0 = \int_0^\infty e^{-z} dz = [-e^{-z}]_0^\infty = (0 + 1) = 1 \quad (2)$$

$$I_1 = - \int_0^\infty (\ln z) e^{-z} dz = \gamma \quad (3)$$

$$I_2 = \gamma^2 + \frac{1}{6}\pi^2 \quad (4)$$

$$I_3 = \gamma^3 + \frac{1}{2}\gamma\pi^2 + 2\zeta(3) \quad (5)$$

$$I_4 = \gamma^4 + \gamma^2\pi^2 - \frac{3}{20}\pi^4 + 8\gamma\zeta(3), \quad (6)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\zeta(3)$  is APÉRY'S CONSTANT.

## Euler Measure

Define the Euler measure of a polyhedral set as the EULER INTEGRAL of its indicator function. It is easy to show by induction that the Euler measure of a closed bounded convex POLYHEDRON is always 1 (independent of dimension), while the Euler measure of a  $d$ -D relative-open bounded convex POLYHEDRON is  $(-1)^d$ .

## Euler Number

The Euler numbers, also called the SECANT NUMBERS or ZIG NUMBERS, are defined for  $|x| < \pi/2$  by

$$\operatorname{sech} x - 1 \equiv -\frac{E_1^* x^2}{2!} + \frac{E_2^* x^4}{4!} - \frac{E_3^* x^6}{6!} + \dots \quad (1)$$

$$\sec x - 1 \equiv \frac{E_1^* x^2}{2!} + \frac{E_2^* x^4}{4!} + \frac{E_3^* x^6}{6!} + \dots, \quad (2)$$

where  $\operatorname{sech}$  is the HYPERBOLIC SECANT and  $\sec$  is the SECANT. Euler numbers give the number of ODD ALTERNATING PERMUTATIONS and are related to GENOCCHI NUMBERS. The base  $e$  of the NATURAL LOGARITHM is sometimes known as Euler's number.

Some values of the Euler numbers are

$$E_1^* = 1$$

$$E_2^* = 5$$

$$E_3^* = 61$$

$$E_4^* = 1,385$$

$$E_5^* = 50,521$$

$$E_6^* = 2,702,765$$

$$E_7^* = 199,360,981$$

$$E_8^* = 19,391,512,145$$

$$E_9^* = 2,404,879,675,441$$

$$E_{10}^* = 370,371,188,237,525$$

$$E_{11}^* = 69,348,874,393,137,901$$

$$E_{12}^* = 15,514,534,163,557,086,905$$

(Sloane's A000364). The first few PRIME Euler numbers  $E_n$  occur for  $n = 2, 3, 19, 227, 255, \dots$  (Sloane's A014547) up to a search limit of  $n = 1415$ .

The slightly different convention defined by

$$E_{2n} = (-1)^n E_n^* \quad (3)$$

$$E_{2n+1} = 0 \quad (4)$$

is frequently used. These are, for example, the Euler numbers computed by the *Mathematica*<sup>®</sup> (Wolfram Research, Champaign, IL) function **EulerE[n]**. This definition has the particularly simple series definition

$$\operatorname{sech} x - 1 \equiv \sum_{k=0}^{\infty} \frac{E_k x^k}{k!} \quad (5)$$

and is equivalent to

$$E_n = 2^n E_n(\tfrac{1}{2}), \quad (6)$$

where  $E_n(x)$  is an EULER POLYNOMIAL.

To confuse matters further, the EULER CHARACTERISTIC is sometimes also called the "Euler number."

see also BERNOULLI NUMBER, EULERIAN NUMBER, EULER POLYNOMIAL, EULER ZIGZAG NUMBER, GENOCCHI NUMBER

**Euler Parameters**

The four parameters  $e_0$ ,  $e_1$ ,  $e_2$ , and  $e_3$  describing a finite rotation about an arbitrary axis. The Euler parameters are defined by

$$e_0 \equiv \cos\left(\frac{\phi}{2}\right) \quad (1)$$

$$\mathbf{e} \equiv \begin{bmatrix} e_1 \\ e_2 \\ e_3 \end{bmatrix} = \hat{\mathbf{n}} \sin\left(\frac{\phi}{2}\right), \quad (2)$$

and are a QUATERNION in scalar-vector representation

$$(e_0, \mathbf{e}) = e_0 + e_1x + e_2j + e_3k. \quad (3)$$

Because EULER'S ROTATION THEOREM states that an arbitrary rotation may be described by only three parameters, a relationship must exist between these four quantities

$$e_0^2 + \mathbf{e} \cdot \mathbf{e} = e_0^2 + e_1^2 + e_2^2 + e_3^2 = 1 \quad (4)$$

(Goldstein 1980, p. 153). The rotation angle is then related to the Euler parameters by

$$\cos \phi = 2e_0^2 - 1 = e_0^2 - \mathbf{e} \cdot \mathbf{e} = e_0^2 - e_1^2 - e_2^2 - e_3^2 \quad (5)$$

$$\hat{\mathbf{n}} \sin \phi = 2\mathbf{e}e_0. \quad (6)$$

The Euler parameters may be given in terms of the EULER ANGLES by

$$e_0 = \cos\left[\frac{1}{2}(\phi + \psi)\right] \cos\left(\frac{1}{2}\theta\right) \quad (7)$$

$$e_1 = \sin\left[\frac{1}{2}(\phi - \psi)\right] \sin\left(\frac{1}{2}\theta\right) \quad (8)$$

$$e_2 = \cos\left[\frac{1}{2}(\phi - \psi)\right] \sin\left(\frac{1}{2}\theta\right) \quad (9)$$

$$e_3 = \sin\left[\frac{1}{2}(\phi + \psi)\right] \cos\left(\frac{1}{2}\theta\right) \quad (10)$$

(Goldstein 1980, p. 155).

Using the Euler parameters, the ROTATION FORMULA becomes

$$\mathbf{r}' = \mathbf{r}(e_0^2 - e_1^2 - e_2^2 - e_3^2) + 2\mathbf{e}(\mathbf{e} \cdot \mathbf{r}) + (\mathbf{r} \times \hat{\mathbf{n}}) \sin \phi, \quad (11)$$

and the ROTATION MATRIX becomes

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = \mathbf{A} \begin{bmatrix} x \\ y \\ z \end{bmatrix}, \quad (12)$$

where the elements of the matrix are

$$a_{ij} = \delta_{ij}(e_0^2 - e_k e_k) + 2e_i e_j + 2\epsilon_{ijk} e_0 e_k. \quad (13)$$

Here, EINSTEIN SUMMATION has been used,  $\delta_{ij}$  is the KRONECKER DELTA, and  $\epsilon_{ijk}$  is the PERMUTATION

SYMBOL. Written out explicitly, the matrix elements are

$$a_{11} = e_0^2 + e_1^2 - e_2^2 - e_3^2 \quad (14)$$

$$a_{12} = 2(e_1 e_2 + e_0 e_3) \quad (15)$$

$$a_{13} = 2(e_1 e_3 - e_0 e_2) \quad (16)$$

$$a_{21} = 2(e_1 e_2 - e_0 e_3) \quad (17)$$

$$a_{22} = e_0^2 - e_1^2 + e_2^2 - e_3^2 \quad (18)$$

$$a_{23} = 2(e_2 e_3 + e_0 e_1) \quad (19)$$

$$a_{31} = 2(e_1 e_3 + e_0 e_2) \quad (20)$$

$$a_{32} = 2(e_2 e_3 - e_0 e_1) \quad (21)$$

$$a_{33} = e_0^2 - e_1^2 - e_2^2 + e_3^2. \quad (22)$$

## Euler Polyhedral Formula

see POLYHEDRAL FORMULA

## Euler Polynomial

A POLYNOMIAL  $E_n(x)$  given by the sum

$$\frac{2e^{xt}}{e^t + 1} = \sum_{n=0}^{\infty} E_n(x) \frac{t^n}{n!}. \quad (1)$$

Euler polynomials are related to the BERNOULLI NUMBERS by

$$E_{n-1}(x) = \frac{2^n}{n} \left[ B_n \left( \frac{x+1}{2} \right) - B_n \left( \frac{x}{2} \right) \right] \quad (2)$$

$$= \frac{2}{n} \left[ B_n(x) - 2^n B_n \left( \frac{x}{2} \right) \right] \quad (3)$$

$$E_{n-2}(x) = 2 \binom{n-1}{2}^{-1} \sum_{k=0}^{n-2} \binom{n}{k} [(2^{n-k} - 1) B_{n-k} B_k(x)], \quad (4)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. Setting  $x = 1/2$  and normalizing by  $2^n$  gives the EULER NUMBER

$$E_n = 2^n E_n \left( \frac{1}{2} \right). \quad (5)$$

Call  $E'_n = E_n(0)$ , then the first few terms are  $-1/2, 0, 1/4, -1/2, 0, 17/8, 0, 31/2, 0, \dots$ . The terms are the same but with the SIGNS reversed if  $x = 1$ . These values can be computed using the double sum

$$E_n(0) = 2^{-n} \sum_{j=1}^n \left[ (-1)^{j+n+1} j^k \sum_{k=0}^{n-j} \binom{n+1}{k} \right]. \quad (6)$$

The BERNOULLI NUMBERS  $B_n$  for  $n > 1$  can be expressed in terms of the  $E'_n$  by

$$B_n = -\frac{n E'_{n-1}}{2(2^n - 1)}. \quad (7)$$

see EULER FOUR-SQUARE IDENTITY

## Euler Power Conjecture

see EULER'S SUM OF POWERS CONJECTURE

## Euler Product

For  $\sigma > 1$ ,

$$\zeta(\sigma) = \sum_{n=1}^{\infty} \frac{1}{n^\sigma} = \prod_p \frac{1}{1 - \frac{1}{p^\sigma}},$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION.

$$e^\gamma = \lim_{n \rightarrow \infty} \frac{1}{\ln n} \prod_{i=1}^n \frac{1}{1 - \frac{1}{p_i}},$$

where the product is over PRIMES  $p$ , where  $\gamma$  is the EULER-MASCHERONI CONSTANT.

see also DEDEKIND FUNCTION

## Euler Pseudoprime

Euler pseudoprimes to a base  $a$  are ODD COMPOSITE numbers such that  $(a, n) = 1$  and the JACOBI SYMBOL satisfies

$$\left( \frac{a}{n} \right) \equiv a^{(n-1)/2} \pmod{n}.$$

No ODD COMPOSITE number is an Euler pseudoprime for all bases  $a$  RELATIVELY PRIME to it. This class includes some CARMICHAEL NUMBERS and all STRONG PSEUDOPRIMES to base  $a$ . An Euler pseudoprime is pseudoprime to at most  $1/2$  of all possible bases less than itself. The first few Euler pseudoprimes are 341, 561, 1105, 1729, 1905, 2047, ... (Sloane's A006970).

## Euler's Quadratic Residue Theorem

A number  $D$  that possesses no common divisor with a prime number  $p$  is either a QUADRATIC RESIDUE or non-residue of  $p$ , depending whether  $D^{(p-1)/2}$  is congruent mod  $p$  to  $\pm 1$ .

**Euler Quartic Conjecture**

Euler conjectured that there are no POSITIVE INTEGER solutions to the quartic DIOPHANTINE EQUATION

$$A^4 + B^4 = C^4 + D^4.$$

This conjecture was disproved by N. D. Elkies in 1988, who found an infinite class of solutions.

**Euler's Rotation Theorem**

An arbitrary ROTATION may be described by only three parameters.

see also EULER ANGLES, EULER PARAMETERS, ROTATION MATRIX

**Euler's Rule**

The numbers  $2^n pq$  and  $2^n r$  are AMICABLE NUMBERS if the three INTEGERS

$$\begin{aligned} p &\equiv 2^m(2^{n-m} + 1) - 1 \\ q &\equiv 2^m(2^{n-m} + 1) - 1 \\ r &\equiv 2^{n+m}(2^{n-m} + 1)^2 - 1 \end{aligned}$$

are all PRIME numbers for some POSITIVE INTEGER  $m$  satisfying  $1 \leq m \leq n - 1$  (Dickson 1952, p. 42). However, there are exotic AMICABLE NUMBERS which do not satisfy Euler's rule, so it is a SUFFICIENT but not NECESSARY condition for amicability.

see also AMICABLE NUMBERS

**Euler's Series Transformation**

Accelerates the rate of CONVERGENCE for an ALTERNATING SERIES

$$\begin{aligned} S &= \sum_{s=0}^{\infty} (-1)^s u_s \\ &= u_0 - u_1 + u_2 - \dots - u_{n-1} + \sum_{s=0}^{\infty} \frac{(-1)^2}{2^{s+1}} [\Delta^s u_n] \quad (1) \end{aligned}$$

for  $n$  EVEN and  $\Delta$  the FORWARD DIFFERENCE operator

$$\Delta^k u_n \equiv \sum_{m=0}^k (-1)^m \binom{k}{m} u_{n+k-m}, \quad (2)$$

where  $\binom{k}{m}$  are BINOMIAL COEFFICIENTS. The POSITIVE terms in the series can be converted to an ALTERNATING SERIES using

$$\sum_{r=1}^{\infty} v_r = \sum_{r=1}^{\infty} (-1)^{r-1} w_r, \quad (3)$$

where

$$w_r \equiv v_r + 2v_{2r} + 4v_{4r} + 8v_{8r} + \dots \quad (4)$$

see also ALTERNATING SERIES

**Euler's Spiral**

see CORNU SPIRAL

**Euler Square**

A square ARRAY made by combining  $n$  objects of two types such that the first and second elements form LATIN SQUARES. Euler squares are also known as GRAECO-LATIN SQUARES, GRAECO-ROMAN SQUARES, or LATIN-GRAECO SQUARES. For many years, Euler squares were known to exist for  $n = 3, 4$ , and for every ODD  $n$  except  $n = 3k$ . EULER'S GRAECO-ROMAN SQUARES CONJECTURE maintained that there do not exist Euler squares of order  $n = 4k + 2$  for  $k = 1, 2, \dots$ . However, such squares were found to exist in 1959, refuting the CONJECTURE.

**Euler Sum**

In response to a letter from Goldbach, Euler considered DOUBLE SUMS of the form

$$s(m, n) = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2} + \dots + \frac{1}{k}\right)^m (k+1)^{-n} \quad (1)$$

$$= \sum_{k=1}^{\infty} [\gamma + \psi_0(k+1)]^m (k+1)^{-n} \quad (2)$$

with  $m \geq 1$  and  $n \geq 2$  and where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\Psi(x) = \psi_0(x)$  is the DIGAMMA FUNCTION. Euler found explicit formulas in

terms of the RIEMANN ZETA FUNCTION for  $s(1, n)$  with  $n \geq 2$ , and E. Au-Yeung numerically discovered

$$\sum_{k=1}^{\infty} \left(1 + \frac{1}{2} + \dots + \frac{1}{k}\right)^2 k^{-2} = \frac{17}{4} \zeta(4), \quad (3)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION, which was subsequently rigorously proven true (Borwein and Borwein 1995). Sums involving  $k^{-n}$  can be re-expressed in terms of sums the form  $(k+1)^{-n}$  via

$$\begin{aligned} \sum_{k=1}^{\infty} \left(1 + \frac{1}{2^m} + \dots + \frac{1}{k^m}\right) k^{-n} \\ = \sum_{k=0}^{\infty} \left[1 + \frac{2}{2^m} + \dots + \frac{1}{(k+1)^m}\right] (k+1)^{-n} \\ = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2^m} + \dots + \frac{1}{k^m}\right) (k+1)^{-n} + \sum_{k=1}^{\infty} k^{-(m+n)} \\ \equiv \sigma_h(m, n) + \zeta(m+n) \end{aligned} \quad (4)$$

and

$$\begin{aligned} \sum_{k=1}^{\infty} \left(1 + \frac{1}{2} + \dots + \frac{1}{k}\right)^2 k^{-n} \\ = s_h(2, n) + 2s_h(1, n+1) + \zeta(n+2), \end{aligned} \quad (5)$$

where  $\sigma_h$  is defined below.

Bailey *et al.* (1994) subsequently considered sums of the forms

$$s_h(m, n) = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2} + \dots + \frac{1}{k}\right)^m (k+1)^{-n} \quad (6)$$

$$s_a(m, n) = \sum_{k=1}^{\infty} \left[1 - \frac{1}{2} + \dots + \frac{(-1)^{k+1}}{k}\right]^m (k+1)^{-n} \quad (7)$$

$$\alpha_h(m, n) = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2} + \dots + \frac{1}{k}\right)^m (-1)^{k+1} (k+1)^{-n} \quad (8)$$

$$\alpha_a(m, n) = \sum_{k=1}^{\infty} \left(1 - \frac{1}{2} + \dots + \frac{(-1)^{k+1}}{k}\right)^m (-1)^{k+1} (k+1)^{-n} \quad (9)$$

$$\sigma_h(m, n) = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2^m} + \dots + \frac{1}{k^m}\right) (k+1)^{-n} \quad (10)$$

$$\sigma_a(m, n) = \sum_{k=1}^{\infty} \left(1 - \frac{1}{2^m} + \dots + \frac{(-1)^{k+1}}{k^m}\right) (k+1)^{-n} \quad (11)$$

$$\alpha_h(m, n) = \sum_{k=1}^{\infty} \left(1 + \frac{1}{2^m} + \dots + \frac{1}{k^m}\right) (-1)^{k+1} (k+1)^{-n} \quad (12)$$

$$\alpha_a(m, n) = \sum_{k=1}^{\infty} \left(1 - \frac{1}{2^m} + \dots + \frac{(-1)^{k+1}}{k^m}\right) (-1)^{k+1} (k+1)^{-n}, \quad (13)$$

where  $s_h$  and  $s_a$  have the special forms

$$s_h = \sum_{k=1}^{\infty} [\gamma + \psi_0(n+1)]^m k + 1^{-n} \quad (14)$$

$$\begin{aligned} a_a = \sum_{k=1}^{\infty} \left\{ \ln 2 + \frac{1}{2}(-1)^n \right. \\ \left. \times [\psi_0(\frac{1}{2}n + \frac{1}{2}) - \psi_0(\frac{1}{2}n + 1)] \right\}^m (k+1)^{-m}. \end{aligned} \quad (15)$$

Analytic single or double sums over  $\zeta(z)$  can be constructed for

$$s_h(1, n) = \frac{1}{2} n \zeta(n+1) - \frac{1}{2} \sum_{k=1}^{n-2} \zeta(n-k) \zeta(k+1) \quad (16)$$

$$\begin{aligned} s_h(2, n) = \frac{1}{3} n(n+1) \zeta(n+2) + \zeta(2) \zeta(n) \\ - \frac{1}{2} n \sum_{k=0}^{n-2} \zeta(n-k) \zeta(k+2) \\ + \frac{1}{3} \sum_{k=2}^{n-2} \zeta(n-k) \sum_{j=1}^{k-1} \zeta(j+1) \zeta(k+1-j) + \sigma_h(2, n) \end{aligned} \quad (17)$$

$$\begin{aligned} s_h(2, 2n-1) = \frac{1}{6} (2n^2 - 7n - 3) \zeta(2n+1) + \zeta(2) \zeta(2n-1) \\ - \frac{1}{2} \sum_{k=1}^{n-2} (2k-1) \zeta(2n-1-2k) \zeta(2k+2) \\ + \frac{1}{3} \sum_{k=1}^{n-2} \zeta(2k+1) \sum_{j=1}^{n-2-k} \zeta(2j+1) \zeta(2n-1-2k-2j) \end{aligned} \quad (18)$$

$$\sigma_h(1, n) = s_h(1, n) \quad (19)$$

$$\begin{aligned} \sigma_h(2, 2n-1) = -\frac{1}{2} (2n^2 + n + 1) \zeta(2n+1) + \zeta(2) \zeta(2n-1) \\ + \sum_{k=1}^{n-1} 2k \zeta(k+1) \zeta(2n-2k) \end{aligned} \quad (20)$$

$$\begin{aligned} \sigma_h(m \text{ even}, n \text{ odd}) = \frac{1}{2} \left[ \binom{m+n}{m} - 1 \right] \zeta(m+n) + \zeta(m) \zeta(n) \\ - \sum_{j=1}^{m+n} \left[ \binom{2j-2}{m-1} + \binom{2j-2}{n-1} \right] \\ \times \zeta(2j-1) \zeta(m+n-2j+1) \end{aligned} \quad (21)$$

$$\begin{aligned} \sigma_h(m \text{ odd}, n \text{ even}) = -\frac{1}{2} \left[ \binom{m+n}{m} + 1 \right] \zeta(m+n) \\ + \sum_{k=1}^{m+n} \left[ \binom{2j-2}{m-1} + \binom{2j-2}{n-1} \right] \\ \times \zeta(2j-1) \zeta(m+n-2j+1), \end{aligned} \quad (22)$$

where  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT. Explicit formulas inferred using the PSLQ ALGORITHM include

$$s_h(2, 2) = \frac{3}{2} \zeta(4) + \frac{1}{2} [\zeta(2)]^2 \quad (23)$$

$$= \frac{11}{360} \pi^4 \quad (24)$$

$$s_h(2, 4) = \frac{2}{3}\zeta(6) - \frac{1}{3}\zeta(2)\zeta(4) + \frac{1}{3}[\zeta(2)]^3 - [\zeta(3)]^2 \quad (25)$$

$$= \frac{37}{22680}\pi^6 - [\zeta(3)]^2 \quad (26)$$

$$s_h(3, 2) = \frac{15}{2}\zeta(5) + \zeta(2)\zeta(3) \quad (27)$$

$$s_h(3, 3) = -\frac{33}{16}\zeta(6) + 2[\zeta(3)]^2 \quad (28)$$

$$s_h(3, 4) = \frac{119}{16}\zeta(7) - \frac{33}{4}\zeta(3)\zeta(4) + 2\zeta(2)\zeta(5) \quad (29)$$

$$s_h(3, 6) = \frac{197}{24}\zeta(9) - \frac{33}{4}\zeta(4)\zeta(5) - \frac{37}{8}\zeta(3)\zeta(6) \\ + [\zeta(3)]^3 + 3\zeta(2)\zeta(7) \quad (30)$$

$$s_h(4, 2) = \frac{859}{24}\zeta(6) + 3[\zeta(3)]^2 \quad (31)$$

$$s_h(4, 3) = -\frac{109}{8}\zeta(7) + \frac{37}{2}\zeta(3)\zeta(4) - 5\zeta(2)\zeta(5) \quad (32)$$

$$s_h(4, 5) = -\frac{29}{2}\zeta(9) + \frac{37}{2}\zeta(4)\zeta(5) + \frac{33}{4}\zeta(3)\zeta(6) \\ - \frac{8}{3}[\zeta(3)]^3 - 7\zeta(2)\zeta(7) \quad (33)$$

$$s_h(5, 2) = \frac{1855}{16}\zeta(7) + 33\zeta(3)\zeta(4) + \frac{57}{2}\zeta(2)\zeta(5) \quad (34)$$

$$s_h(5, 4) = \frac{890}{9}\zeta(9) + 66\zeta(4)\zeta(5) - \frac{4295}{24}\zeta(3)\zeta(6) - 5[\zeta(3)]^3 \\ + \frac{265}{8}\zeta(2)\zeta(7) \quad (35)$$

$$s_h(6, 3) = -\frac{3073}{12}\zeta(9) - 243\zeta(4)\zeta(5) + \frac{2097}{4}\zeta(3)\zeta(6) \\ + \frac{67}{3}[\zeta(3)]^3 - \frac{651}{8}\zeta(2)\zeta(7) \quad (36)$$

$$s_h(7, 2) = \frac{134701}{36}\zeta(9) + \frac{15697}{8}\zeta(4)\zeta(5) + \frac{29555}{24}\zeta(3)\zeta(6) \\ + 56[\zeta(3)]^3 + \frac{3287}{4}\zeta(2)\zeta(7), \quad (37)$$

$$s_a(2, 2) = 6\text{Li}_4(\frac{1}{2}) + \frac{1}{4}(\ln 2)^4 - \frac{29}{8}\zeta(4) + \frac{3}{2}\zeta(2)(\ln 2)^2 \quad (38)$$

$$s_a(2, 3) = 4\text{Li}_5(\frac{1}{2}) - \frac{1}{30}(\ln 2)^5 - \frac{17}{32}\zeta(5) - \frac{11}{8}\zeta(4)\ln 2 \\ + \frac{7}{4}\zeta(3)(\ln 2)^2 + \frac{1}{3}\zeta(2)(\ln 2)^3 - \frac{3}{4}\zeta(2)\zeta(3), \quad (39)$$

$$s_a(3, 2) = -24\text{Li}_5(\frac{1}{2}) + 6\ln 2\text{Li}_4(\frac{1}{2}) + \frac{9}{20}(\ln 2)^5 + \frac{659}{32}\zeta(5) \\ - \frac{285}{16}\zeta(4)\ln 2 + \frac{5}{2}\zeta(2)(\ln 2)^3 + \frac{1}{2}\zeta(2)\zeta(3), \quad (40)$$

$$a_h(2, 2) = -2\text{Li}_4(\frac{1}{2}) - \frac{1}{12}(\ln 2)^4 + \frac{99}{48}\zeta(4) - \frac{7}{4}\zeta(3)\ln 2 \\ + \frac{1}{2}\zeta(2)(\ln 2)^2 \quad (41)$$

$$a_h(2, 3) = -4\text{Li}_5(\frac{1}{2}) - 4(\ln 2)\text{Li}_4(\frac{1}{2}) - \frac{2}{15}(\ln 2)^5 + \frac{107}{32}\zeta(5) \\ - \frac{7}{4}\zeta(3)(\ln 2)^2 + \frac{2}{3}\zeta(2)(\ln 2)^3 + \frac{3}{8}\zeta(2)\zeta(3) \quad (42)$$

$$a_h(3, 2) = 6\text{Li}_5(\frac{1}{2}) + 6(\ln 2)\text{Li}_4(\frac{1}{2}) + \frac{1}{5}(\ln 2)^5 - \frac{33}{8}\zeta(5) \\ + \frac{21}{8}\zeta(3)(\ln 2)^2 - \zeta(2)(\ln 2)^3 - \frac{15}{16}\zeta(2)\zeta(3), \quad (43)$$

and

$$a_a(2, 2) = -4\text{Li}_4(\frac{1}{2}) - \frac{1}{6}(\ln 2)^4 + \frac{37}{16}\zeta(4) + \frac{7}{4}\zeta(3)(\ln 2) \\ - 2\zeta(2)(\ln 2)^2 \quad (44)$$

$$a_a(2, 3) = 4(\ln 2)\text{Li}_4(\frac{1}{2}) + \frac{1}{6}(\ln 2)^5 - \frac{79}{32}\zeta(5) \\ + \frac{11}{8}\zeta(4)(\ln 2) - \zeta(2)(\ln 2)^3 + \frac{3}{8}\zeta(2)\zeta(3) \quad (45)$$

$$a_a(3, 2) = 30\text{Li}_5(\frac{1}{2}) - \frac{1}{4}(\ln 2)^5 - \frac{1813}{64}\zeta(5) \\ + \frac{285}{16}\zeta(4)(\ln 2) + \frac{21}{8}\zeta(3)(\ln 2)^2 \\ - \frac{7}{2}\zeta(2)(\ln 2)^3 + \frac{3}{4}\zeta(2)\zeta(3), \quad (46)$$

where  $\text{Li}_n$  is a POLYLOGARITHM, and  $\zeta(z)$  is the RIEMANN ZETA FUNCTION (Bailey and Plouffe). Of these, only  $s_h(3, 2)$ ,  $s_h(3, 3)$  and the identities for  $s_a(m, n)$ ,  $a_h(m, n)$  and  $a_a(m, n)$  have been rigorously established.

### Euler's Sum of Powers Conjecture

Euler conjectured that at least  $n$   $n$ th POWERS are required for  $n > 2$  to provide a sum that is itself an  $n$ th POWER. The conjecture was disproved by Lander and Parkin (1967) with the counterexample

$$27^5 + 84^5 + 110^5 + 133^5 = 144^5.$$

### Euler Totient Function

see TOTIENT FUNCTION

**Euler's Totient Rule**

The number of bases mod  $p$  in which  $1/p$  has cycle length  $l$  is the same as the number of FRACTIONS  $0/(p-1)$ ,  $1/(p-1)$ ,  $\dots$ ,  $(p-2)/(p-1)$  which have least DENOMINATOR  $l$ .

see also TOTIENT FUNCTION

**References**

Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, pp. 167-168, 1996.

**Euler's Transform**

A technique for SERIES CONVERGENCE IMPROVEMENT which takes a convergent alternating series

$$\sum_{k=0}^{\infty} (-1)^k a_k = a_0 - a_1 + a_2 - \dots \quad (1)$$

into a series with more rapid convergence to the same value to

$$s = \sum_{k=0}^{\infty} \frac{(-1)^k \Delta^k a_0}{2^{k+1}}, \quad (2)$$

where the FORWARD DIFFERENCE is defined by

$$\Delta^k a_0 = \sum_{m=0}^k \equiv (-1)^m \binom{k}{m} a_{k-m} \quad (3)$$

(Abramowitz and Stegun 1972; Beeler *et al.* 1972, Item 120).

see also FORWARD DIFFERENCE

**Euler Transformation**

see EULER'S FINITE DIFFERENCE TRANSFORMATION, EULER'S HYPERGEOMETRIC TRANSFORMATIONS, EULER'S TRANSFORM

**Euler's Triangle**

The triangle of numbers  $A_{n,k}$  given by

$$A_{n,1} = A_{n,n} = 1$$

and the RECURRENCE RELATION

$$A_{n+1,k} = kA_{n,k} + (n+2-k)A_{n,k-1}$$

for  $k \in [2, n]$ , where  $A_{n,k}$  are EULERIAN NUMBERS.

$$\begin{array}{ccccccc} & & & & 1 & & \\ & & & & & 1 & 1 \\ & & & & & & 1 & 4 & 1 \\ & & & & 1 & 11 & 11 & 1 \\ & & & 1 & 26 & 66 & 26 & 1 \\ & & 1 & 57 & 302 & 302 & 57 & 1 \\ & 1 & 120 & 1191 & 2416 & 1191 & 120 & 1. \end{array}$$

The numbers 1, 1, 1, 1, 4, 1, 1, 11, 11, 1, ... are Sloane's A008292. Amazingly, the Z-TRANSFORMS of  $t^n$

$$\frac{(z-1)^n}{T^n z} Z[t^n] = \frac{(1-z)^n}{T^n z} \lim_{x \rightarrow 0} \frac{\partial^n}{\partial x^n} \left( \frac{z}{z - e^{-xT}} \right)$$

are generators for Euler's triangle.

**Eulerian Circuit**

An EULERIAN TRAIL which starts and ends at the same VERTEX. In other words, it is a CYCLE which uses each EDGE exactly once. The term EULERIAN CYCLE is also used synonymously with Eulerian circuit. For technical reasons, Eulerian circuits are easier to study mathematically than are HAMILTONIAN CIRCUITS. As a generalization of the KÖNIGSBERG BRIDGE PROBLEM, Euler showed (without proof) that a CONNECTED GRAPH has an Eulerian circuit IFF it has no VERTICES of ODD DEGREE.

see also EULER GRAPH, HAMILTONIAN CIRCUIT

**Eulerian Cycle**

see EULERIAN CIRCUIT

**Eulerian Integral of the First Kind**

Legendre and Whittaker and Watson's (1990) term for the BETA FUNCTION.

**References**

Whittaker, E. T. and Watson, G. N. *A Course in Modern Analysis, 4th ed.* Cambridge, England: Cambridge University Press, 1990.

**Eulerian Integral of the Second Kind**

$$\begin{aligned}\Pi(z, n) &\equiv \int_0^n \left(1 - \frac{t}{n}\right)^n t^{z-1} dt = n^z \int_0^1 (1 - \tau)^n \tau^{z-1} d\tau \\ &= \frac{n!}{z(z+1) \cdots (z+n)} n^z.\end{aligned}$$

**Eulerian Number**

The number of PERMUTATIONS of length  $n$  with  $k \leq n$  RUNS, denoted  $\langle n \rangle_k$ ,  $A_{n,k}$ , or  $A(n, k)$ . The Eulerian numbers are given explicitly by the sum

$$\langle n \rangle_k = \sum_{j=0}^k (-1)^j \binom{n+1}{j} (k-j)^n. \quad (1)$$

Making the definition

$$b_{n,1} = 1 \quad (2)$$

$$b_{1,n} = 1 \quad (3)$$

together with the RECURRENCE RELATION

$$b_{n,k} = nb_{n,k-1} + kb_{n-1,k} \quad (4)$$

for  $n > k$  then gives

$$\langle n \rangle_k = b_{k,n-k+1}. \quad (5)$$

The arrangement of the numbers into a triangle gives EULER'S TRIANGLE, whose entries are 1, 1, 1, 1, 4, 1,

1, 11, 11, 1, ... (Sloane's A008292). Therefore, they represent a sort of generalization of the BINOMIAL COEFFICIENTS where the defining RECURRENCE RELATION weights the sum of neighbors by their row and column numbers, respectively.

The Eulerian numbers satisfy

$$\sum_{k=1}^n \langle n \rangle_k = n!. \quad (6)$$

Eulerian numbers also arise in the surprising context of integrating the SINC FUNCTION, and also in sums of the form

$$\sum_{k=1}^n k^n r^k = \text{Li}_{-n}(r) = \frac{r}{(1-r)^{n+1}} \sum_{i=1}^n \langle n \rangle_i r^{n-i}, \quad (7)$$

where  $\text{Li}_m(z)$  is the POLYLOGARITHM function.

**Eulerian Trail**

A WALK on the EDGES of a GRAPH which uses each EDGE exactly once. A CONNECTED GRAPH has an Eulerian trail IFF it has at most two VERTICES of ODD DEGREE.

see also EULERIAN CIRCUIT

**Eutactic Star**

An orthogonal projection of a CROSS onto a 3-D SUBSPACE. It is said to be normalized if the CROSS vectors are all of unit length.

see also HADWIGER'S PRINCIPAL THEOREM

**Evans Point**

The intersection of the GERGONNE LINE and the EULER LINE. It does not appear to have a simple parametric representation.

**References**

**Eve**

see APPLE, ROOT, SNAKE, SNAKE EYES, SNAKE OIL METHOD, SNAKE POLYAMOND

**Even Function**

A function  $f(x)$  such that  $f(x) = f(-x)$ . An even function times an ODD FUNCTION is odd.

**Even Number**

An INTEGER of the form  $N = 2n$ , where  $n$  is an INTEGER. The even numbers are therefore  $\dots, -4, -2, 0, 2, 4, 6, 8, 10, \dots$  (Sloane's A005843). Since the even numbers are integrally divisible by two,  $N \equiv 0 \pmod{2}$  for even  $N$ . An even number  $N$  for which  $N \equiv 2 \pmod{4}$  is called a SINGLY EVEN NUMBER, and an even number  $N$  for which  $N \equiv 0 \pmod{4}$  is called a DOUBLY EVEN NUMBER. An integer which is not even is called an ODD NUMBER. The GENERATING FUNCTION of the even numbers is

$$\frac{2x}{(x-1)^2} = 2x + 4x^2 + 6x^3 + 8x^4 + \dots$$

see also DOUBLY EVEN NUMBER, EVEN FUNCTION, ODD NUMBER, SINGLY EVEN NUMBER

**References**

Sloane, N. J. A. Sequence A005843/M0985 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Eventually Periodic**

A PERIODIC SEQUENCE such as  $\{1, 1, 1, 2, 1, 2, 1, 2, 1, 2, 1, 2, \dots\}$  which is periodic from some point onwards.

see also PERIODIC SEQUENCE

**Everett's Formula**

$$f_p = (1-p)f_0 + pf_1 + E_2\delta_0^2 + F_2\delta_1^2 + E_4\delta_0^4 + F_4\delta_1^4 + E_6\delta_0^6 + F_6\delta_1^6 + \dots, \quad (1)$$

for  $p \in [0, 1]$ , where  $\delta$  is the CENTRAL DIFFERENCE and

$$E_{2n} \equiv G_{2n} - G_{2n+1} \equiv B_{2n} - B_{2n+1} \quad (2)$$

$$F_{2n} \equiv G_{2n+1} \equiv B_{2n} + B_{2n+1}, \quad (3)$$

where  $G_k$  are the COEFFICIENTS from GAUSS'S BACKWARD FORMULA and GAUSS'S FORWARD FORMULA and  $B_k$  are the COEFFICIENTS from BESSEL'S FINITE DIFFERENCE FORMULA. The  $E_k$ s and  $F_k$ s also satisfy

$$E_{2n}(p) = F_{2n}(q) \quad (4)$$

$$F_{2n}(p) = E_{2n}(q), \quad (5)$$

for

$$q \equiv 1 - p. \quad (6)$$

see also BESSEL'S FINITE DIFFERENCE FORMULA

**Everett Interpolation**

see EVERETT'S FORMULA

**Eversion**

A curve on the unit sphere  $S^2$  is an eversion if it has no corners or cusps (but it may be self-intersecting). These properties are guaranteed by requiring that the curve's velocity never vanishes. A mapping  $\sigma: S^1 \rightarrow S^2$  forms an immersion of the CIRCLE into the SPHERE IFF, for all  $\theta \in \mathbb{R}$ ,

$$\left| \frac{d}{d\theta} [\sigma(e^{i\theta})] \right| > 0.$$

Smale (1958) showed it is possible to turn a SPHERE inside out (SPHERE EVERSION) using eversion.

see also SPHERE EVERSION

**References**

Smale, S. "A Classification of Immersions of the Two-Sphere." *Trans. Amer. Math. Soc.* **90**, 281–290, 1958.

**Evolute**

An evolute is the locus of centers of curvature (the envelope) of a plane curve's normals. The original curve is then said to be the INVOLUTE of its evolute. Given a plane curve represented parametrically by  $(f(t), g(t))$ , the equation of the evolute is given by

$$x = f - R \sin \tau \quad (1)$$

$$y = g + R \cos \tau, \quad (2)$$

where  $(x, y)$  are the coordinates of the running point,  $R$  is the RADIUS OF CURVATURE

$$R = \frac{(f'^2 + g'^2)^{3/2}}{f'g'' - f''g'}, \quad (3)$$

and  $\tau$  is the angle between the unit TANGENT VECTOR

$$\hat{\mathbf{T}} = \frac{\mathbf{x}'}{|\mathbf{x}'|} = \frac{1}{\sqrt{f'^2 + g'^2}} \begin{bmatrix} f' \\ g' \end{bmatrix} \quad (4)$$

and the  $x$ -AXIS,

$$\cos \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{x}} \quad (5)$$

$$\sin \tau = \hat{\mathbf{T}} \cdot \hat{\mathbf{y}}. \quad (6)$$

Combining gives

$$x = f - \frac{(f'^2 + g'^2)g'}{f'g'' - f''g'} \quad (7)$$

$$y = g + \frac{(f'^2 + g'^2)f'}{f'g'' - f''g'}. \quad (8)$$

The definition of the evolute of a curve is independent of parameterization for any differentiable function (Gray 1993). If  $E$  is the evolute of a curve  $I$ , then  $I$  is said to be the INVOLUTE of  $E$ . The centers of the OSCULATING CIRCLES to a curve form the evolute to that curve (Gray 1993, p. 90).

The following table lists the evolutes of some common curves.

Curve	Evolute
astroid	astroid 2 times as large
cardioid	cardioid 1/3 as large
cayley's sextic	nephroid
circle	point (0, 0)
cycloid	equal cycloid
deltoid	deltoid 3 times as large
ellipse	Lamé curve
epicycloid	enlarged epicycloid
hypocycloid	similar hypocycloid
limaçon	circle catacaustic for a point source
logarithmic spiral	equal logarithmic spiral
nephroid	nephroid 1/2 as large
parabola	Neile's parabola
tractrix	catenary

see also INVOLUTE, OSCULATING CIRCLE

### Exact Covering System

A system of congruences  $a_i \bmod n_i$  with  $1 \leq i \leq k$  is called a COVERING SYSTEM if every INTEGER  $y$  satisfies  $y \equiv a_i \pmod{n_i}$  for at least one value of  $i$ . A covering system in which each integer is covered by just one congruence is called an exact covering system.

see also COVERING SYSTEM

#### References

- Guy, R. K. "Exact Covering Systems." §F14 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 253–256, 1994.

### Exact Differential

A differential of the form

$$df = P(x, y) dx + Q(x, y) dy \quad (1)$$

is exact (also called a TOTAL DIFFERENTIAL) if  $\int df$  is path-independent. This will be true if

$$df = \frac{\partial f}{\partial x} dx + \frac{\partial f}{\partial y} dy, \quad (2)$$

so  $P$  and  $Q$  must be of the form

$$P(x, y) = \frac{\partial f}{\partial x} \quad Q(x, y) = \frac{\partial f}{\partial y}. \quad (3)$$

But

$$\frac{\partial P}{\partial y} = \frac{\partial^2 f}{\partial y \partial x} \quad (4)$$

$$\frac{\partial Q}{\partial x} = \frac{\partial^2 f}{\partial x \partial y}, \quad (5)$$

so

$$\frac{\partial P}{\partial y} = \frac{\partial Q}{\partial x}. \quad (6)$$

see also PFAFFIAN FORM, INEXACT DIFFERENTIAL

### Exact Period

see LEAST PERIOD

### Exact Trilinear Coordinates

The TRILINEAR COORDINATES  $\alpha : \beta : \gamma$  of a point  $P$  relative to a TRIANGLE are PROPORTIONAL to the directed distances  $a' : b' : c'$  from  $P$  to the side lines (i.e.,  $a' : b' : c' = k\alpha : k\beta : k\gamma$ ). Letting  $k$  be the constant of proportionality,

$$k \equiv \frac{2\Delta}{a\alpha + b\beta + c\gamma},$$

where  $\Delta$  is the AREA of  $\triangle ABC$  and  $a$ ,  $b$ , and  $c$  are the lengths of its sides. When the trilinears are chosen so that  $k = 1$ , the coordinates are known as exact trilinear coordinates.

see also TRILINEAR COORDINATES

**Exactly One**

"Exactly one" means "one and only one," sometimes also referred to as "JUST ONE." J. H. Conway has also humorously suggested "once" (one and only one) by analogy with IFF (if and only if), "twoo" (two and only two), and "threee" (three and only three). This refinement is sometimes needed in formal mathematical discourse because, for example, if you have two apples, you also have one apple, but you do not have *exactly one* apple.

In 2-valued LOGIC, exactly one is equivalent to the exclusive or operator XOR,

$$P(E) \text{ XOR } P(F) = P(E) + P(F) - 2P(E \cap F).$$

see also IFF, PRECISELY UNLESS, XOR

**Exactly When**

see IFF

**Excenter**

The center  $J_i$  of an EXCIRCLE. There are three excenters for a given TRIANGLE, denoted  $J_1$ ,  $J_2$ ,  $J_3$ . The INCENTER  $I$  and excenters  $J_i$  of a TRIANGLE are an ORTHOCENTRIC SYSTEM.

$$\overline{OI}^2 + \overline{OJ_1}^2 + \overline{OJ_2}^2 + \overline{OJ_3}^2 = 12R^2,$$

where  $O$  is the CIRCUMCENTER,  $J_i$  are the excenters, and  $R$  is the CIRCUMRADIUS (Johnson 1929, p. 190). Denote the MIDPOINTS of the original TRIANGLE  $M_1$ ,  $M_2$ , and  $M_3$ . Then the lines  $J_1M_1$ ,  $J_2M_2$ , and  $J_3M_3$  intersect in a point known as the MITTENPUNKT.

see also CENTROID (ORTHOCENTRIC SYSTEM), EXCENTER-EXCENTER CIRCLE, EXCENTRAL TRIANGLE, EXCIRCLE, INCENTER, MITTENPUNKT

**References**

Dixon, R. *Mathographics*. New York: Dover, pp. 58–59, 1991.  
Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, 1929.

**Excenter-Excenter Circle**

Given a TRIANGLE  $\Delta A_1A_2A_3$ , the points  $A_1$ ,  $I$ , and  $J_1$  lie on a line, where  $I$  is the INCENTER and  $J_1$  is the EXCENTER corresponding to  $A_1$ . Furthermore, the circle with  $J_2J_3$  as the diameter has  $Q$  as its center, where  $P$  is the intersection of  $A_1J_1$  with the CIRCUMCIRCLE of  $A_1A_2A_3$  and  $Q$  is the point opposite  $P$  on the CIRCUMCIRCLE. The circle with diameter  $J_2J_3$  also passes through  $A_2$  and  $A_3$  and has radius

$$r = \frac{1}{2}a_1 \csc\left(\frac{1}{2}\alpha_1\right) = 2R \cos\left(\frac{1}{2}\alpha_1\right).$$

It arises because the points  $I$ ,  $J_1$ ,  $J_2$ , and  $J_3$  form an ORTHOCENTRIC SYSTEM.

see also EXCENTER, INCENTER-EXCENTER CIRCLE, ORTHOCENTRIC SYSTEM

**References**

Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, pp. 185–186, 1929.

**Excentral Triangle**

The TRIANGLE  $J = \Delta J_1J_2J_3$  with VERTICES corresponding to the EXCENTERS of a given TRIANGLE  $A$ , also called the TRITANGENT TRIANGLE.

Beginning with an arbitrary TRIANGLE  $A$ , find the excentral triangle  $J$ . Then find the excentral triangle  $J'$  of that TRIANGLE, and so on. Then the resulting TRIANGLE  $J^{(\infty)}$  approaches an EQUILATERAL TRIANGLE.

Call  $T$  the TRIANGLE tangent externally to the EXCIRCLES of  $A$ . Then the INCENTER  $I_T$  of  $K$  coincides with the CIRCUMCENTER  $C_J$  of TRIANGLE  $\Delta J_1 J_2 J_3$ , where  $J_i$  are the EXCENTERS of  $A$ . The INRADIUS  $r_T$  of the INCIRCLE of  $T$  is

$$r_T = 2R + r = \frac{1}{2}(r + r_1 + r_2 + r_3),$$

where  $R$  is the CIRCUMRADIUS of  $A$ ,  $r$  is the INRADIUS, and  $r_i$  are the EXRADII (Johnson 1929, p. 192).

see ABUNDANT NUMBER

#### Excircle

Given a TRIANGLE, extend two nonadjacent sides. The CIRCLE tangent to these two lines and to the other side of the TRIANGLE is called an ESCRIBED CIRCLE, or excircle. The CENTER  $J_i$  of the excircle is called the EXCENTER and lies on the external ANGLE BISECTOR of the opposite ANGLE. Every TRIANGLE has three excircles, and the TRILINEAR COORDINATES of the EXCENTERS are  $-1 : 1 : 1$ ,  $1 : -1 : 1$ , and  $1 : 1 : -1$ . The RADIUS  $r_i$  of the excircle  $i$  is called its EXRADIUS.

Given a TRIANGLE with INRADIUS  $r$ , let  $h_i$  be the ALTITUDES of the excircles, and  $r_i$  their RADII (the EXRADII). Then

$$\frac{1}{h_1} + \frac{1}{h_2} + \frac{1}{h_3} = \frac{1}{r_1} + \frac{1}{r_2} + \frac{1}{r_3} = \frac{1}{r}$$

(Johnson 1929, p. 189).

#### References

Coxeter, H. S. M. and Greitzer, S. L. *Geometry Revisited*. Washington, DC: Math. Assoc. Amer., pp. 11-13, 1967.  
Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, pp. 176-177 and 182-194, 1929.

#### Excision Axiom

One of the EILENBERG-STEENROD AXIOMS which states that, if  $X$  is a SPACE with SUBSPACES  $A$  and  $U$  such that the CLOSURE of  $A$  is contained in the interior of  $U$ , then the INCLUSION MAP  $(X \cup A \cup U) \rightarrow (X, A)$  induces an isomorphism  $H_n(X \cup A \cup U) \rightarrow H_n(X, A)$ .

#### Excluded Middle Law

A law in (2-valued) LOGIC which states there is no third alternative to TRUTH or FALSEHOOD. In other words, every statement must be either  $A$  or not- $A$ . This fact no longer holds in THREE-VALUED LOGIC or FUZZY LOGIC.

#### Excludent

A method which can be used to solve any QUADRATIC CONGRUENCE. This technique relies on the fact that solving

$$x^2 \equiv b \pmod{p}$$

is equivalent to finding a value  $y$  such that

$$b + py = x^2.$$

Pick a few small moduli  $m$ . If  $y \bmod m$  does not make  $b + py$  a quadratic residue of  $m$ , then this value of  $y$  may be excluded. Furthermore, values of  $y > p/4$  are never necessary.

#### Excludent Factorization Method

Also known as the difference of squares. It was first used by Fermat and improved by Gauss. Gauss looked for INTEGERS  $x$  and  $y$  satisfying

$$y^2 \equiv x^2 - N \pmod{E}$$

for various moduli  $E$ . This allowed the exclusion of many potential factors. This method works best when factors are of approximately the same size, so it is sometimes better to attempt  $mN$  for some suitably chosen value of  $m$ .

see also PRIME FACTORIZATION ALGORITHMS

#### Exclusive Or

see XOR

**Exeter Point**

Define  $A'$  to be the point (other than the VERTEX  $A$ ) where the MEDIAN through  $A$  meets the CIRCUMCIRCLE of  $ABC$ , and define  $B'$  and  $C'$  similarly. Then the Exeter point is the PERSPECTIVE CENTER of the TRIANGLE  $A'B'C'$  and the TANGENTIAL TRIANGLE. It has TRIANGLE CENTER FUNCTION

$$\alpha = a(b^4 + c^4 - a^4).$$

**Exogenous Variable**

An economic variable that is related to other economic variables and determines their equilibrium levels.

see also ENDOGENOUS VARIABLE

References

- Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics*. Cambridge, MA: MIT Press, p. 458, 1980.

**Exotic  $\mathbb{R}^4$** 

Donaldson (1983) showed there exists an exotic smooth DIFFERENTIAL STRUCTURE on  $\mathbb{R}^4$ . Donaldson's result has been extended to there being precisely a CONTINUUM of nondiffeomorphic DIFFERENTIAL STRUCTURES on  $\mathbb{R}^4$ .

see also EXOTIC SPHERE

References

- Donaldson, S. K. "Self-Dual Connections and the Topology of Smooth 4-Manifold." *Bull. Amer. Math. Soc.* **8**, 81–83, 1983.  
 Monastyrsky, M. *Modern Mathematics in the Light of the Fields Medals*. Wellesley, MA: A. K. Peters, 1997.

**Exotic Sphere**

Milnor (1963) found more than one smooth structure on the 7-D HYPERSPHERE. Generalizations have subsequently been found in other dimensions. Using SURGERY theory, it is possible to relate the number of DIFFEOMORPHISM classes of exotic spheres to higher homotopy groups of spheres (Kosinski 1992). Kervaire and Milnor (1963) computed a list of the number  $N(d)$  of distinct (up to DIFFEOMORPHISM) DIFFERENTIAL STRUCTURES on spheres indexed by the DIMENSION  $d$  of the sphere. For  $d = 1, 2, \dots$ , assuming the POINCARÉ CONJECTURE, they are 1, 1, 1,  $\geq 1$ , 1, 1, 28, 2, 8, 6, 992, 1, 3, 2, 16256, 2, 16, 16,  $\dots$  (Sloane's A001676). The status of  $d = 4$  is still unresolved: at least one exotic structure exists, but it is not known if others do as well.

The only exotic Euclidean spaces are a CONTINUUM of EXOTIC  $\mathbb{R}^4$  structures.

**Exp**

see EXPONENTIAL FUNCTION

**Expansion**

An AFFINE TRANSFORMATION in which the scale is increased. It is the opposite of a DILATION (CONTRACTION).

see also DILATION

**Expansive**

Let  $\phi$  be a MAP. Then  $\phi$  is expansive if the DISTANCE  $d(\phi^n x, \phi^n y) < \delta$  for all  $n \in \mathbb{Z}$ , then  $x = y$ . Equivalently,  $\phi$  is expansive if the orbits of two points  $x$  and  $y$  are always very close.

**Expectation Value**

For one discrete variable,

$$\langle f(x) \rangle = \sum_x P(x). \quad (1)$$

For one continuous variable,

$$\langle f(x) \rangle = \int f(x) P(x) dx. \quad (2)$$

The expectation value satisfies

$$\langle ax + by \rangle = a\langle x \rangle + b\langle y \rangle \quad (3)$$

$$\langle a \rangle = a \quad (4)$$

$$\left\langle \sum x \right\rangle = \sum \langle x \rangle. \quad (5)$$

For multiple discrete variables

$$\langle f(x_1, \dots, x_n) \rangle = \sum_{x_1, \dots, x_n} P(x_1, \dots, x_n). \quad (6)$$

For multiple continuous variables

$$\begin{aligned} \langle f(x_1, \dots, x_n) \rangle \\ = \int f(x_1, \dots, x_n) P(x_1, \dots, x_n) dx_1 \cdots dx_n. \end{aligned} \quad (7)$$

The (multiple) expectation value satisfies

$$\begin{aligned} \langle (x - \mu_x)(y - \mu_y) \rangle &= \langle xy - \mu_x y - \mu_y x + \mu_x \mu_y \rangle \\ &= \langle xy \rangle - \mu_x \mu_y - \mu_y \mu_x + \mu_x \mu_y \\ &= \langle xy \rangle - \langle x \rangle \langle y \rangle, \end{aligned} \quad (8)$$

where  $\mu_i$  is the MEAN for the variable  $i$ .

see also MEAN

**Experimental Design**

see DESIGN

**Exploration Problem**

see JEEP PROBLEM

**Exponent**

The POWER  $p$  in an expression  $a^p$ .

**Exponent Laws**

The laws governing the combination of EXPONENTS (POWERS) are

$$x^m \cdot x^n = x^{m+n} \quad (1)$$

$$\frac{x^m}{x^n} = x^{m-n} \quad (2)$$

$$(x^m)^n = x^{mn} \quad (3)$$

$$(xy)^m = x^m y^m \quad (4)$$

$$\left(\frac{x}{y}\right)^n = \frac{x^n}{y^n} \quad (5)$$

$$x^{-n} = \frac{1}{x^n} \quad (6)$$

$$\left(\frac{x}{y}\right)^{-n} = \left(\frac{y}{x}\right)^n, \quad (7)$$

where quantities in the DENOMINATOR are taken to be nonzero. Special cases include

$$x^1 = x \quad (8)$$

and

$$x^0 = 1 \quad (9)$$

for  $x \neq 0$ . The definition  $0^0 = 1$  is sometimes used to simplify formulas, but it should be kept in mind that this equality is a definition and not a fundamental mathematical truth.

see also EXPONENT, POWER

**Exponent Vector**

Let  $p_i$  denote the  $i$ th PRIME, and write

$$m = \prod_i p_i^{v_i}.$$

Then the exponent vector is  $\mathbf{v}(m) = (v_1, v_2, \dots)$ .

**Exponential Digital Invariant**

see NARCISSISTIC NUMBER

**Exponential Distribution**

Given a POISSON DISTRIBUTION with rate of change  $\lambda$ , the distribution of waiting times between successive changes (with  $k = 0$ ) is

$$D(x) \equiv P(X \leq x) = 1 - P(X > x) \\ = 1 - \frac{(\lambda x)^0 e^{-\lambda x}}{0!} = 1 - e^{-\lambda x} \quad (1)$$

$$P(x) = D'(x) = \lambda e^{-\lambda x}, \quad (2)$$

which is normalized since

$$\int_0^\infty P(x) dx = \lambda \int_0^\infty e^{-\lambda x} dx \\ = -[e^{-\lambda x}]_0^\infty = -(0 - 1) = 1. \quad (3)$$

This is the only MEMORYLESS RANDOM DISTRIBUTION. Define the MEAN waiting time between successive changes as  $\theta \equiv \lambda^{-1}$ . Then

$$P(x) = \begin{cases} \frac{1}{\theta} e^{-x/\theta} & x \geq 0 \\ 0 & x < 0. \end{cases} \quad (4)$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \int_0^\infty e^{tx} \left( \frac{1}{\theta} \right) e^{-x/\theta} dx = \frac{1}{\theta} \int_0^\infty e^{-(1-\theta t)x/\theta} dx \\ = \left[ \frac{e^{-(1-\theta t)x/\theta}}{1-\theta t} \right]_0^\infty = \frac{1}{1-\theta t} \quad (5)$$

$$M'(t) = \frac{\theta}{(1-\theta t)^2} \quad (6)$$

$$M''(t) = \frac{2\theta^2}{(1-\theta t)^3}, \quad (7)$$

so

$$R(t) \equiv \ln M(t) = -\ln(1-\theta t) \quad (8)$$

$$R'(t) = \frac{\theta}{1-\theta t} \quad (9)$$

$$R''(t) = \frac{\theta^2}{(1-\theta t)^2} \quad (10)$$

$$\mu = R'(0) = \theta \quad (11)$$

$$\sigma^2 = R''(0) = \theta^2. \quad (12)$$

The SKEWNESS and KURTOSIS are given by

$$\gamma_1 = 2 \quad (13)$$

$$\gamma_2 = 6. \quad (14)$$

The MEAN and VARIANCE can also be computed directly

$$\langle x \rangle = \int_0^\infty P(x) dx = \frac{1}{s} \int_0^\infty x e^{-x/s} dx. \quad (15)$$

Use the integral

$$\int x e^{ax} dx = \frac{e^{ax}}{a^2} (ax - 1) \quad (16)$$

to obtain

$$\langle x \rangle = \frac{1}{s} \left[ \frac{e^{-x/s}}{\left(-\frac{1}{s}\right)^2} \left\{ \left(-\frac{1}{s}\right) x - 1 \right\} \right]_0^\infty \\ = -s \left[ e^{-x/s} \left( 1 + \frac{x}{s} \right) \right]_0^\infty \\ = -s(0 - 1) = s. \quad (17)$$

Now, to find

$$\langle x^2 \rangle = \frac{1}{s} \int_0^\infty x^2 e^{-x/s} dx, \quad (18)$$

use the integral

$$\int x^2 e^{-x/s} dx = \frac{e^{-ax}}{a^3} (2 - 2ax + a^2 x^2) \quad (19)$$

$$\langle x^2 \rangle = \frac{1}{s} \left[ \frac{e^{-x/s}}{\left(-\frac{1}{s}\right)^3} \left( 2 + \frac{2}{s} x + \frac{1}{s^2} x^2 \right) \right]_0^\infty \\ = -s^2(0 - 2) = 2s^2, \quad (20)$$

giving

$$\sigma^2 \equiv \langle x^2 \rangle - \langle x \rangle^2 \\ = 2s^2 - s^2 = s^2 \quad (21)$$

$$\sigma \equiv \sqrt{\text{var}(x)} = s. \quad (22)$$

If a generalized exponential probability function is defined by

$$P_{(\alpha, \beta)}(x) = \frac{1}{\beta} e^{-(x-\alpha)/\beta}, \quad (23)$$

then the CHARACTERISTIC FUNCTION is

$$\phi(t) = \frac{e^{i\alpha t}}{1 - i\beta t}, \quad (24)$$

and the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \alpha + \beta \quad (25)$$

$$\sigma^2 = \beta^2 \quad (26)$$

$$\gamma_1 = 2 \quad (27)$$

$$\gamma_2 = 6. \quad (28)$$

see also DOUBLE EXPONENTIAL DISTRIBUTION

## Exponential Divisor

see *e*-DIVISOR

## Exponential Function

The exponential function is defined by

$$\exp(x) \equiv e^x, \quad (1)$$

where  $e$  is the constant 2.718... It satisfies the identity

$$\exp(x + y) = \exp(x) \exp(y). \quad (2)$$

If  $z \equiv x + iy$ ,

$$e^z = e^{x+iy} = e^x e^{iy} = e^x (\cos y + i \sin y). \quad (3)$$

If

$$a + bi = e^{x+iy}, \quad (4)$$

then

$$y = \tan^{-1} \left( \frac{b}{a} \right) \quad (5)$$

$$\begin{aligned} x &= \ln \left\{ b \csc \left[ \tan^{-1} \left( \frac{b}{a} \right) \right] \right\} \\ &= \ln \left\{ a \sec \left[ \tan^{-1} \left( \frac{b}{a} \right) \right] \right\}. \end{aligned} \quad (6)$$

The above plot shows the function  $e^{1/z}$ .

## Exponential Function (Truncated)

see EXPONENTIAL SUM FUNCTION

## Exponential Inequality

For  $c < 1$ ,

$$x^c < 1 + c(x - 1).$$

For  $c > 1$ ,

$$x^c > 1 + c(x - 1).$$

## Exponential Integral

Let  $E_1(x)$  be the  $E_n$ -FUNCTION with  $n = 1$ ,

$$E_1(x) \equiv \int_1^\infty \frac{e^{-tx} dt}{t} = \int_x^\infty \frac{e^{-u} du}{u}. \quad (1)$$

Then define the exponential integral  $ei(x)$  by

$$E_1(x) = -ei(-x), \quad (2)$$

where the retention of the  $-ei(-x)$  NOTATION is a historical artifact. Then  $ei(x)$  is given by the integral

$$ei(x) = - \int_{-x}^\infty \frac{e^{-t} dt}{t}. \quad (3)$$

This function is given by the *Mathematica*® (Wolfram Research, Champaign, IL) function `ExpIntegralEi[x]`. The exponential integral can also be written

$$ei(ix) = ci(x) + i si(x), \quad (4)$$

where  $ci(x)$  and  $si(x)$  are COSINE and SINE INTEGRAL.

The real ROOT of the exponential integral occurs at 0.37250741078..., which is not known to be expressible in terms of other standard constants. The quantity  $-e \operatorname{ei}(-1) = 0.596347362\dots$  is known as the GOMPERTZ CONSTANT.

### Exponential Map

On a LIE GROUP,  $\exp$  is a MAP from the LIE ALGEBRA to its LIE GROUP. If you think of the LIE ALGEBRA as the TANGENT SPACE to the identity of the LIE GROUP,  $\exp(v)$  is defined to be  $h(1)$ , where  $h$  is the unique LIE GROUP HOMEOMORPHISM from the REAL NUMBERS to the LIE GROUP such that its velocity at time 0 is  $v$ .

On a RIEMANNIAN MANIFOLD,  $\exp$  is a MAP from the TANGENT BUNDLE of the MANIFOLD to the MANIFOLD, and  $\exp(v)$  is defined to be  $h(1)$ , where  $h$  is the unique GEODESIC traveling through the base-point of  $v$  such that its velocity at time 0 is  $v$ .

The three notions of  $\exp$  ( $\exp$  from COMPLEX ANALYSIS,  $\exp$  from LIE GROUPS, and  $\exp$  from Riemannian geometry) are all linked together, the strongest link being between the LIE GROUPS and Riemannian geometry definition. If  $G$  is a compact LIE GROUP, it admits a left and right invariant RIEMANNIAN METRIC. With respect to that metric, the two  $\exp$  maps agree on their common domain. In other words, one-parameter subgroups are geodesics. In the case of the MANIFOLD  $\mathbb{S}^1$ , the CIRCLE, if we think of the tangent space to 1 as being the IMAGINARY axis ( $y$ -AXIS) in the COMPLEX PLANE, then

$$\begin{aligned}\exp_{\text{Riemannian geometry}}(v) &= \exp_{\text{Lie Groups}}(v) \\ &= \exp_{\text{complex analysis}}(v),\end{aligned}$$

and so the three concepts of the exponential all agree in this case.

see also EXPONENTIAL FUNCTION

### Exponential Matrix

### Exponential Sum Formulas

$$\begin{aligned}\sum_{n=0}^{N-1} e^{iNx} &= \frac{1 - e^{iNx}}{1 - e^{ix}} = \frac{-e^{iNx/2} (e^{-iNx/2} - e^{iNx/2})}{-e^{ix/2} (e^{-ix/2} - e^{ix/2})} \\ &= \frac{\sin(\frac{1}{2}Nx)}{\sin(\frac{1}{2}x)} e^{ix(N-1)/2},\end{aligned}\quad (1)$$

where

$$\sum_{n=0}^{N-1} r^n = \frac{1 - r^N}{1 - r} \quad (2)$$

has been used. Similarly,

$$\begin{aligned}\sum_{n=0}^{N-1} p^n e^{inx} &= \frac{1 - p^N e^{iNx}}{1 - pe^{ix}} = \frac{(1 - p^N e^{iNx})(1 - pe^{-ix})}{(1 - pe^{ix})(1 - pe^{-ix})} \\ &= \frac{1 - p^N e^{iNx} - pe^{-ix} + p^{N+1} e^{ix(N-1)}}{1 - p(e^{ix} + e^{-ix}) + p^2} \\ &= \frac{p^{N+1} e^{ix(N-1)} - p^N e^{iNx} + 1 - pe^{-ix}}{1 - 2p \cos x + p^2}.\end{aligned}\quad (3)$$

This gives

$$\sum_{n=0}^{\infty} p^n e^{inx} = \lim_{N \rightarrow \infty} \sum_{n=0}^{N-1} p^n e^{inx} = \frac{1 - pe^{-ix}}{1 - 2p \cos x + p^2}.\quad (4)$$

By looking at the REAL and IMAGINARY PARTS of these FORMULAS, sums involving sines and cosines can be obtained.

**Exponential Sum Function**

$$\text{es}_n(x) \equiv \exp_n(x) \equiv \sum_{m=0}^n \frac{x^m}{m!}.$$

see also GAMMA FUNCTION

**Exradius**

The RADIUS of an EXCIRCLE. Let a TRIANGLE have exradius  $r_a$  (sometimes denoted  $\rho_a$ ), opposite side of length  $a$ , AREA  $\Delta$ , and SEMIPERIMETER  $s$ . Then

$$r_a^2 = \left( \frac{\Delta}{s-a} \right)^2 \quad (1)$$

$$= \frac{s(s-c)(s-b)}{s-a} \quad (2)$$

$$= 4R \sin(\tfrac{1}{2}\alpha_1) \cos(\tfrac{1}{2}\alpha_2) \cos(\tfrac{1}{2}\alpha_3) \quad (3)$$

(Johnson 1929, p. 189) where  $R$  is the CIRCUMRADIUS. Let  $r$  be the INRADIUS, then

$$4R = r_a + r_b + r_c - r \quad (4)$$

$$\frac{1}{r_a} + \frac{1}{r_b} + \frac{1}{r_c} = \frac{1}{r} \quad (5)$$

$$rr_ar_br_c = \Delta^2. \quad (6)$$

Some fascinating FORMULAS due to Feuerbach are

$$r_2r_3 + r_3r_1 + r_1r_3 = s^2 \quad (7)$$

$$r(r_2r_3 + r_3r_1 + r_1r_2) = s\Delta = r_1r_2r_3 \quad (8)$$

$$r(r_1 + r_2 + r_3) = a_2a_3 + a_3a_1 + a_1a_2 - s^2 \quad (9)$$

$$rr_1 + rr_2 + rr_3 + r_1r_2 + r_2r_3 + r_3r_1 = a_2a_3 + a_3a_1 + a_1a_2 \quad (10)$$

$$r_2r_3 + r_3r_1 + r_1r_2 - rr_1 - rr_2 - rr_3 - \tfrac{1}{2}(a_1^2 + a_2^2 + a_3^2) \quad (11)$$

(Johnson 1929, pp. 190–191).

**Extension Problem**

Given a SUBSPACE  $A$  of a SPACE  $X$  and a MAP from  $A$  to a SPACE  $Y$ , is it possible to extend that MAP to a MAP from  $X$  to  $Y$ ?

see also LIFTING PROBLEM

## Extensions Calculus

see EXTERIOR ALGEBRA

### Extent

The RADIUS of the smallest CIRCLE centered at one of the points of an N-CLUSTER, which contains all the points in the N-CLUSTER.

see also N-CLUSTER

### Exterior

That portion of a region lying "outside" a specified boundary.

see also INTERIOR

### Exterior Algebra

The ALGEBRA of the EXTERIOR PRODUCT, also called an ALTERNATING ALGEBRA or GRASSMANN ALGEBRA. The study of exterior algebra is also called AUSDEHNUNGSLEHRE and EXTENSIONS CALCULUS. Exterior algebras are GRADED ALGEBRAS.

In particular, the exterior algebra of a VECTOR SPACE is the DIRECT SUM over  $k$  in the natural numbers of the VECTOR SPACES of alternating  $k$ -forms on that VECTOR SPACE. The product on this algebra is then the wedge product of forms. The exterior algebra for a VECTOR SPACE  $V$  is constructed by forming monomials  $u, v \wedge w, x \wedge y \wedge z$ , etc., where  $u, v, w, x, y$ , and  $z$  are vectors in  $V$  and  $\wedge$  is asymmetric multiplication. The sums formed from linear combinations of the MONOMIALS are the elements of an exterior algebra.

Forder, H. G. *The Calculus of Extension*. Cambridge, England: Cambridge University Press, 1941.

Lounesto, P. "Counterexamples to Theorems Published and Proved in Recent Literature on Clifford Algebras, Spinors, Spin Groups, and the Exterior Algebra." <http://www.hit.fi/~lounesto/counterexamples.htm>.

### Exterior Angle Bisector

The exterior bisector of an ANGLE is the LINE or LINE SEGMENT which cuts it into two equal ANGLES on the opposite "side" as the ANGLE.

For a TRIANGLE, the exterior angle bisector bisects the SUPPLEMENTARY ANGLE at a given VERTEX. It also divides the opposite side externally in the ratio of adjacent sides.

see also ANGLE BISECTOR, ISODYNAMIC POINTS

### Exterior Angle Theorem

In any TRIANGLE, if one of the sides is extended, the exterior angle is greater than both the interior and opposite angles.

#### References

Dunham, W. *Journey Through Genius: The Great Theorems of Mathematics*. New York: Wiley, p. 41, 1990.

### Exterior Derivative

Consider a DIFFERENTIAL  $k$ -FORM

$$\omega^1 = b_1 dx_1 + b_2 dx_2. \quad (1)$$

Then its exterior derivative is

$$d\omega^1 = db_1 \wedge dx_1 + db_2 \wedge dx_2, \quad (2)$$

where  $\wedge$  is the WEDGE PRODUCT. Similarly, consider

$$\omega^1 = b_1(x_1, x_2) dx_1 + b_2(x_1, x_2) dx_2. \quad (3)$$

Then

$$\begin{aligned} d\omega^1 &= db_1 \wedge dx_1 + db_2 \wedge dx_2 \\ &= \left( \frac{\partial b_1}{\partial x_1} dx_1 + \frac{\partial b_1}{\partial x_2} dx_2 \right) \wedge dx_1 \\ &\quad + \left( \frac{\partial b_2}{\partial x_1} dx_1 + \frac{\partial b_2}{\partial x_2} dx_2 \right) \wedge dx_2. \end{aligned} \quad (4)$$

Denote the exterior derivative by

$$Dt \equiv \frac{\partial}{\partial x} \wedge t. \quad (5)$$

Then for a 0-form  $t$ ,

$$(Dt)_\mu \equiv \frac{\partial t}{\partial x^\mu}, \quad (6)$$

for a 1-form  $t$ ,

$$(Dt)_{\mu\nu} \equiv \frac{1}{2} \left( \frac{\partial t_\nu}{\partial x^\mu} - \frac{\partial t_\mu}{\partial x^\nu} \right), \quad (7)$$

and for a 2-form  $t$ ,

$$(Dt)_{ijk} \equiv \frac{1}{3} \epsilon_{ijk} \left( \frac{\partial t_{23}}{\partial x^1} + \frac{\partial t_{31}}{\partial x^2} + \frac{\partial t_{12}}{\partial x^3} \right), \quad (8)$$

where  $\epsilon_{ijk}$  is the PERMUTATION TENSOR.

The second exterior derivative is

$$D^2 t = \frac{\partial}{\partial x} \wedge \left( \frac{\partial}{\partial x} \wedge t \right) = \left( \frac{\partial}{\partial x} \wedge \frac{\partial}{\partial x} \right) \wedge t = 0, \quad (9)$$

which is known as POINCARÉ'S LEMMA.

see also DIFFERENTIAL  $k$ -FORM, POINCARÉ'S LEMMA, WEDGE PRODUCT

**Exterior Dimension**

A type of DIMENSION which can be used to characterize FAT FRACTALS.

**Extrapolation**

see RICHARDSON EXTRAPOLATION

**Extremal Coloring**

see EXTREMAL GRAPH

**Extremal Graph**

A two-coloring of a COMPLETE GRAPH  $K_n$  of  $n$  nodes which contains exactly the number  $N \equiv (R + B)_{\min}$  of MONOCHROMATIC FORCED TRIANGLES and no more (i.e., a minimum of  $R + B$  where  $R$  and  $B$  are the numbers of red and blue TRIANGLES). Goodman (1959) showed that for an extremal graph,

$$N(n) = \begin{cases} \frac{1}{3}m(m-1)(m-2) & \text{for } n = 2m \\ \frac{1}{3}2m(m-1)(4m+1) & \text{for } n = 4m+1 \\ \frac{1}{3}2m(m+1)(4m-1) & \text{for } n = 4m+3. \end{cases}$$

This is sometimes known as GOODMAN'S FORMULA. Schwenk (1972) rewrote it in the form

$$N(n) = \binom{n}{3} - \left\lfloor \frac{1}{2}n \left\lfloor \frac{1}{4}(n-1)^2 \right\rfloor \right\rfloor,$$

sometimes known as SCHWENK'S FORMULA, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION. The first few values of  $N(n)$  for  $n = 1, 2, \dots$  are 0, 0, 0, 0, 0, 2, 4, 8, 12, 20, 28, 40, 52, 70, 88, ... (Sloane's A014557).

**Extremals**

A field of extremals is a plane region which is SIMPLY CONNECTED by a one-parameter family of extremals. The concept was invented by Weierstraß.

**Extreme and Mean Ratio**

see GOLDEN MEAN

**Extreme Value Distribution**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $M_n$  denote the "extreme" (i.e., largest) ORDER STATISTIC  $X^{(n)}$  for a distribution of  $n$  elements  $X_i$  taken from a continuous UNIFORM DISTRIBUTION. Then the distribution of the  $M_n$  is

$$P(M_n < x) = \begin{cases} 0 & \text{if } x < 0 \\ x^n & \text{if } 0 \leq x \leq 1 \\ 1 & \text{if } x > 1, \end{cases} \quad (1)$$

and the MEAN and VARIANCE are

$$\mu = \frac{n}{n+1} \quad (2)$$

$$\sigma^2 = \frac{n}{(n+1)^2(n+2)}. \quad (3)$$

If  $X_i$  are taken from a STANDARD NORMAL DISTRIBUTION, then its cumulative distribution is

$$F(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt = \frac{1}{2} + \Phi(x), \quad (4)$$

where  $\Phi(x)$  is the NORMAL DISTRIBUTION FUNCTION. The probability distribution of  $M_n$  is then

$$P(M_n < x) = [F(x)]^n = \frac{n}{\sqrt{2\pi}} \int_{-\infty}^x [F(t)]^{n-1} e^{-t^2/2} dt. \quad (5)$$

The MEAN  $\mu(n)$  and VARIANCE  $\sigma^2(n)$  are expressible in closed form for small  $n$ ,

$$\mu(1) = 0 \quad (6)$$

$$\mu(2) = \frac{1}{\sqrt{\pi}} \quad (7)$$

$$\mu(3) = \frac{3}{2\sqrt{\pi}} \quad (8)$$

$$\mu(4) = \frac{3}{2\sqrt{\pi}} \left[ 1 + \frac{2}{\pi} \sin^{-1}\left(\frac{1}{3}\right) \right] \quad (9)$$

$$\mu(5) = \frac{5}{4\sqrt{\pi}} \left[ 1 + \frac{6}{\pi} \sin^{-1}\left(\frac{1}{3}\right) \right] \quad (10)$$

and

$$\sigma^2(1) = 1 \quad (11)$$

$$\sigma^2(2) = 1 - \frac{1}{\pi} \quad (12)$$

$$\sigma^2(3) = \frac{4\pi - 9 + 2\sqrt{3}}{4\pi} \quad (13)$$

$$\sigma^2(4) = 1 + \frac{\sqrt{3}}{\pi} - [\mu(4)]^2 \quad (14)$$

$$\sigma^2(5) = 1 + \frac{5\sqrt{3}}{4\pi} + \frac{5\sqrt{3}}{2\pi^2} \sin^{-1}\left(\frac{1}{4}\right) - [\mu(5)]^2. \quad (15)$$

No exact expression is known for  $\mu(6)$  or  $\sigma^2(6)$ , but there is an equation connecting them

$$[\mu(6)]^2 + \sigma^2(6) = 1 + \frac{5\sqrt{3}}{4\pi} + \frac{15\sqrt{3}}{2\pi^2} \sin^{-1}\left(\frac{1}{4}\right). \quad (16)$$

An analog to the CENTRAL LIMIT THEOREM states that the asymptotic normalized distribution of  $M_n$  satisfies one of the three distributions

$$P(y) = \exp(-e^{-y}) \quad (17)$$

$$P(y) = \begin{cases} 0 & \text{if } y \leq 0 \\ \exp(-y^{-a}) & \end{cases} \quad (18)$$

$$P(y) = \begin{cases} \exp[-(-y)^a] & \text{if } y \leq 0 \\ 1 & \text{if } y > 0, \end{cases} \quad (19)$$

also known as GUMBEL, Fréchet, and WEIBULL DISTRIBUTIONS, respectively.

## Extreme Value Theorem

If a function  $f$  is continuous on a closed interval  $[a, b]$ , then  $f$  has both a MAXIMUM and a MINIMUM on  $[a, b]$ . If  $f$  has an extreme value on an open interval  $(a, b)$ , then the extreme value occurs at a CRITICAL POINT. This theorem is sometimes also called the WEIERSTRASS EXTREME VALUE THEOREM.

## Extremum

A MAXIMUM or MINIMUM. An extremum may be LOCAL (a.k.a. a RELATIVE EXTREMUM; an extremum in a given region which is not the overall MAXIMUM or MINIMUM) or GLOBAL. Functions with many extrema can be very difficult to GRAPH. Notorious examples include the functions  $\cos(1/x)$  and  $\sin(1/x)$  near  $x = 0$

and  $\sin(e^{2x+9})$  near 0 and 1.

The latter has

$$\left\lfloor \frac{e^{11}}{\pi} - \frac{1}{2} \right\rfloor - \left\lfloor \frac{e^9}{\pi} - \frac{1}{2} \right\rfloor + 1 = 19058 - 2579 + 1 = 16480$$

extrema in the CLOSED INTERVAL  $[0, 1]$  (Mulcahy 1996).

**Extremum Test**

Consider a function  $f(x)$  in 1-D. If  $f(x)$  has a relative extremum at  $x_0$ , then either  $f'(x_0) = 0$  or  $f$  is not DIFFERENTIABLE at  $x_0$ . Either the first or second DERIVATIVE tests may be used to locate relative extrema of the first kind.

A NECESSARY condition for  $f(x)$  to have a MINIMUM (MAXIMUM) at  $x_0$  is

$$f'(x_0) = 0,$$

and

$$f''(x_0) \geq 0 \quad (f''(x_0) \leq 0).$$

A SUFFICIENT condition is  $f'(x_0) = 0$  and  $f''(x_0) > 0$  ( $f''(x_0) < 0$ ). Let  $f'(x_0) = 0$ ,  $f''(x_0) = 0$ ,  $\dots$ ,  $f^{(n)}(x_0) = 0$ , but  $f^{(n+1)}(x_0) \neq 0$ . Then  $f(x)$  has a RELATIVE MAXIMUM at  $x_0$  if  $n$  is ODD and  $f^{(n+1)}(x_0) < 0$ , and  $f(x)$  has a RELATIVE MINIMUM at  $x_0$  if  $n$  is ODD and  $f^{(n+1)}(x_0) > 0$ . There is a SADDLE POINT at  $x_0$  if  $n$  is EVEN.

**Extrinsic Curvature**

A curvature of a SUBMANIFOLD of a MANIFOLD which depends on its particular EMBEDDING. Examples of extrinsic curvature include the CURVATURE and TORSION of curves in 3-space, or the mean curvature of surfaces in 3-space.

*see also* CURVATURE, INTRINSIC CURVATURE, MEAN CURVATURE

# F

## F-Distribution

Arises in the testing of whether two observed samples have the same VARIANCE. Let  $\chi_m^2$  and  $\chi_n^2$  be independent variates distributed as CHI-SQUARED with  $m$  and  $n$  DEGREES OF FREEDOM. Define a statistic  $F_{n,m}$  as the ratio of the dispersions of the two distributions

$$F_{n,m} \equiv \frac{\chi_n^2/n}{\chi_m^2/m}. \quad (1)$$

This statistic then has an  $F$ -distribution with probability function and cumulative distribution

$$F_{n,m}(x) = \frac{\Gamma(\frac{n+m}{2})n^{n/2}m^{m/2}}{\Gamma(\frac{n}{2})\Gamma(\frac{m}{2})} \frac{x^{n/2-1}}{(m+nx)^{(n+m)/2}} \quad (2)$$

$$= \frac{m^{m/2}n^{n/2}x^{n/2-1}}{(m+nx)^{(n+m)/2}B(\frac{1}{2}n, \frac{1}{2}m)} \quad (3)$$

$$= I(1; \frac{1}{2}m; \frac{1}{2}n) - I\left(\frac{m}{m+nx}; \frac{1}{2}m; \frac{1}{2}n\right), \quad (4)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION,  $B(a,b)$  is the BETA FUNCTION, and  $I(a,b;x)$  is the REGULARIZED BETA FUNCTION. The MEAN, VARIANCE, SKEWNESS and KURTOSIS are

$$\mu = \frac{m}{m-2} \quad (5)$$

$$\sigma^2 = \frac{2m^2(m+n-2)}{n(m-2)^2(m-4)} \quad (6)$$

$$\gamma_1 = \frac{2(m+2n-2)}{m-6} \sqrt{\frac{2(m-4)}{n(m+n-2)}} \quad (7)$$

$$\gamma_2 = \frac{12(-16+20m-8m^2+m^3+44n)}{n(m-6)(m-8)(n+m-2)} + \frac{12(-32mn+5m^2n-22n^2+5mn^2)}{n(m-6)(m-8)(n+m-2)}. \quad (8)$$

The probability that  $F$  would be as large as it is if the first distribution has a smaller variance than the second is denoted  $Q(F_{n,m})$ .

The noncentral  $F$ -distribution is given by

$$P(x) = e^{-\lambda/2 + (\lambda n_1 x)/(2(n_2 + n_1 x))} \times n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1} (n_2 + n_1 x)^{-(n_1+n_2)/2} \times \frac{\Gamma(\frac{1}{2}n_1)\Gamma(1+\frac{1}{2}n_2)L_{n_2/2}^{n_1/2-1}\left(-\frac{\lambda n_1 x}{2(n_2+n_1 x)}\right)}{B(\frac{1}{2}n_1, \frac{1}{2}n_2)\Gamma[\frac{1}{2}(n_1+n_2)]}, \quad (9)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION,  $B(\alpha,\beta)$  is the BETA FUNCTION, and  $L_m^n(z)$  is an associated LAGUERRE POLYNOMIAL.

## F-Ratio Distribution

see  $F$ -DISTRIBUTION

## Fabry Imbedding

A representation of a PLANAR GRAPH as a planar straight line graph such that no two EDGES cross.

## Face

The intersection of an  $n$ -D POLYTOPE with a tangent HYPERPLANE. 0-D faces are known as VERTICES (nodes), 1-D faces as EDGES,  $(n-2)$ -D faces as RIDGES, and  $(n-1)$ -D faces as FACETS.

see also EDGE (POLYHEDRON), FACET, POLYTOPE, RIDGE, VERTEX (POLYHEDRON)

## Facet

An  $(n-1)$ -D FACE of an  $n$ -D POLYTOPE. A procedure for generating facets is known as FACETING.

**Faceting**

Using a set of corners of a SOLID that lie in a plane to form the VERTICES of a new POLYGON is called faceting. Such POLYGONS may outline new FACES that join to enclose a new SOLID, even if the sides of the POLYGONS do not fall along EDGES of the original SOLID.

**Factor**

A factor is a portion of a quantity, usually an INTEGER or POLYNOMIAL. The determination of factors is called FACTORIZATION (or sometimes "FACTORING"). It is usually desired to break factors down into the smallest possible pieces so that no factor is itself factorable. For INTEGERS, the determination of factors is called PRIME FACTORIZATION. For large quantities, the determination of all factors is usually very difficult except in exceptional circumstances.

see also DIVISOR, FACTORIZATION, GREATEST PRIME FACTOR, LEAST PRIME FACTOR, PRIME FACTORIZATION ALGORITHMS

**Factor Base**

The primes with LEGENDRE SYMBOL  $(n/p) = 1$  (less than  $N = \pi(d)$  for trial divisor  $d$ ) which need be considered when using the QUADRATIC SIEVE FACTORIZATION METHOD.

see QUOTIENT SPACE

**Factorial**

The factorial  $n!$  is defined for a POSITIVE INTEGER  $n$  as

$$n! \equiv \begin{cases} n \cdot (n-1) \cdots 2 \cdot 1 & n = 1, 2, \dots \\ 1 & n = 0. \end{cases} \quad (1)$$

The first few factorials for  $n = 0, 1, 2, \dots$  are 1, 1, 2, 6, 24, 120, ... (Sloane's A000142). An older NOTATION for the factorial is  $\underline{n}$  (Dudeney 1970, Gardner 1978, Conway and Guy 1996).

As  $n$  grows large, factorials begin acquiring tails of trailing ZEROS. To calculate the number of trailing ZEROS for  $n!$ , use

$$Z = \sum_{k=1}^{k_{\max}} \left\lfloor \frac{n}{5^k} \right\rfloor, \quad (2)$$

where

$$k_{\max} = \left\lfloor \frac{\ln n}{\ln 5} \right\rfloor \quad (3)$$

and  $\lfloor x \rfloor$  is the FLOOR FUNCTION (Gardner 1978, p. 63; Ogilvy and Anderson 1988, pp. 112–114). For  $n = 1, 2, \dots$ , the number of trailing zeros are 0, 0, 0, 0, 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 3, ... (Sloane's A027868). This is a special application of the general result that the POWER of a PRIME  $p$  dividing  $n!$  is

$$\epsilon_p(n) = \sum_{r \geq 0} \left\lfloor \frac{n}{p^r} \right\rfloor \quad (4)$$

(Graham *et al.* 1994, Vardi 1991). Stated another way, the exact POWER of a PRIME  $p$  which divides  $n!$  is

$$\frac{n - \text{sum of digits of the base-}p \text{ representation of } n}{p - 1}. \quad (5)$$

By noting that

$$n! = \Gamma(n+1), \quad (6)$$

where  $\Gamma(n)$  is the GAMMA FUNCTION for INTEGERS  $n$ , the definition can be generalized to COMPLEX values

$$z! \equiv \Gamma(z+1) \equiv \int_0^\infty e^{-t} t^z dt. \quad (7)$$

This defines  $z!$  for all COMPLEX values of  $z$ , except when  $z$  is a NEGATIVE INTEGER, in which case  $z! = \infty$ . Using the identities for GAMMA FUNCTIONS, the values of  $(\frac{1}{2}n)!$  (half integral values) can be written explicitly

$$(-\frac{1}{2})! = \sqrt{\pi} \quad (8)$$

$$(\frac{1}{2})! = \frac{1}{2}\sqrt{\pi} \quad (9)$$

$$(n - \frac{1}{2})! = \frac{\sqrt{\pi}}{2^n} (2n-1)!! \quad (10)$$

$$(n + \frac{1}{2})! = \frac{\sqrt{\pi}}{2^{n+1}} (2n+1)!!, \quad (11)$$

where  $n!!$  is a DOUBLE FACTORIAL.

For INTEGERS  $s$  and  $n$  with  $s < n$ ,

$$\frac{(s-n)!}{(2s-2n)!} = \frac{(-1)^{n-s}(2n-2s)!}{(n-s)!}. \quad (12)$$

The LOGARITHM of  $z!$  is frequently encountered

$$\ln(z!) = \frac{1}{2} \ln \left[ \frac{\pi z}{\sin(\pi z)} \right] - \gamma - \sum_{n=1}^{\infty} \frac{\zeta(2n+1)}{2n+1} z^{2n+1} \quad (13)$$

$$= \frac{1}{2} \ln \left[ \frac{\pi z}{\sin(\pi z)} \right] - \frac{1}{2} \ln \left( \frac{1+z}{1-z} \right) + (1-\gamma)z - \sum_{n=1}^{\infty} [\zeta(2n+1) - 1] \frac{z^{2n+1}}{2n+1} \quad (14)$$

$$= \ln \left[ \lim_{n \rightarrow \infty} \frac{n!}{(z+1)(z+2) \cdots (z+n)} n^z \right] \quad (15)$$

$$= \lim_{n \rightarrow \infty} [\ln(n!) + z \ln n - \ln(z+1) - \ln(z+2) - \cdots - \ln(z+n)] \quad (16)$$

$$= \sum_{n=1}^{\infty} \frac{z^n}{n!} F_{n-1}(0) \quad (17)$$

$$= -\gamma z + \sum_{n=2}^{\infty} (-1)^n \frac{z^n}{n} \zeta(n) \quad (18)$$

$$= -\ln(1+z) + z(1-\gamma) + \sum_{n=2}^{\infty} (-1)^n [\zeta(n) - 1] \frac{z^n}{n}, \quad (19)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT,  $\zeta$  is the RIEMANN ZETA FUNCTION, and  $F_n$  is the POLYGAMMA FUNCTION. The factorial can be expanded in a series

$$z! = \sqrt{2\pi} z^{z+1/2} e^{-z} \left( 1 + \frac{1}{12} z^{-1} + \frac{1}{288} z^{-2} - \frac{139}{51840} z^{-3} + \cdots \right). \quad (20)$$

STIRLING'S SERIES gives the series expansion for  $\ln(z!)$ ,

$$\begin{aligned} \ln(z!) &= \frac{1}{2} \ln(2\pi) + \left( z + \frac{1}{2} \right) \ln z - z + \frac{B_2}{2z} \\ &\quad + \cdots + \frac{B_{2n}}{2n(2n-1)z^{2n-1}} + \cdots \\ &= \frac{1}{2} \ln(2\pi) + \left( z + \frac{1}{2} \right) \ln z - z + \frac{1}{12} z^{-1} \\ &\quad - \frac{1}{360} z^{-3} + \frac{1}{1260} z^{-5} - \cdots, \end{aligned} \quad (21)$$

where  $B_n$  is a BERNOULLI NUMBER.

Identities satisfied by sums of factorials include

$$\sum_{k=0}^{\infty} \frac{1}{k!} = e = 2.718281828 \dots \quad (22)$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{k!} = e^{-1} = 0.3678794412 \dots \quad (23)$$

$$\sum_{k=0}^{\infty} \frac{1}{(k!)^2} = I_0(2) = 2.279585302 \dots \quad (24)$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(k!)^2} = J_0(2) = 0.2238907791 \dots \quad (25)$$

$$\sum_{k=0}^{\infty} \frac{1}{(2k)!} = \cosh 1 = 1.543080635 \dots \quad (26)$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} = \cos 1 = 0.5403023059 \dots \quad (27)$$

$$\sum_{k=0}^{\infty} \frac{1}{(2k+1)!} = \sinh 1 = 1.175201194 \dots \quad (28)$$

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)!} = \sin 1 = 0.8414709848 \dots \quad (29)$$

(Spanier and Oldham 1987), where  $I_0$  is a MODIFIED BESSEL FUNCTION OF THE FIRST KIND,  $J_0$  is a BESSEL FUNCTION OF THE FIRST KIND,  $\cosh$  is the HYPERBOLIC COSINE,  $\cos$  is the COSINE,  $\sinh$  is the HYPERBOLIC SINE, and  $\sin$  is the SINE.

Let  $h$  be the exponent of the greatest POWER of a PRIME  $p$  dividing  $n!$ . Then

$$h = \sum_{\substack{i=1 \\ p^i \leq n}} \left\lfloor \frac{n}{p^i} \right\rfloor. \quad (30)$$

Let  $g$  be the number of 1s in the BINARY representation of  $n$ . Then

$$g + h = n \quad (31)$$

(Honsberger 1976). In general, as discovered by Legendre in 1808, the POWER  $m$  of the PRIME  $p$  dividing  $n!$  is given by

$$m = \sum_{k=0}^{\infty} \left\lfloor \frac{n}{p^k} \right\rfloor = \frac{n - (n_0 + n_1 + \cdots + n_N)}{p-1}, \quad (32)$$

where the INTEGERS  $n_1, \dots, n_N$  are the digits of  $n$  in base  $p$  (Ribenboim 1989).

The sum-of-factorials function is defined by

$$\begin{aligned} \Sigma(n) &\equiv \sum_{k=1}^n k! \\ &= \frac{-e + \text{ei}(1) + \pi i + E_{2n+1}(-1)\Gamma(n+2)}{e}, \end{aligned} \quad (33)$$

$$= \frac{-e + \text{ei}(1) + \Re[E_{2n+1}(-1)]\Gamma(n+2)}{e}, \quad (34)$$

where  $\text{ei}(1) \approx 1.89512$  is the EXPONENTIAL INTEGRAL,  $E_n$  is the  $E_n$ -FUNCTION, and  $i$  is the IMAGINARY NUMBER. The first few values are 1, 3, 9, 33, 153, 873, 5913, 46233, 409113, ... (Sloane's A007489).  $\Sigma(n)$  cannot be written as a hypergeometric term plus a constant (Petkovšek *et al.* 1996). However the sum

$$\Sigma'(n) \equiv \sum_{k=1}^n k k! = (n+1)! - 1 \quad (35)$$

has a simple form, with the first few values being 1, 5, 23, 119, 719, 5039, ... (Sloane's A033312).

The numbers  $n! + 1$  are prime for  $n = 1, 2, 3, 11, 27, 37, 41, 73, 77, 116, 154, \dots$  (Sloane's A002981), and the numbers  $n! - 1$  are prime for  $n = 3, 4, 6, 7, 12, 14, 30, 32, 33, 38, 94, 166, \dots$  (Sloane's A002982). In general, the power-product sequences (Mudgc 1997) are given by  $S_k^\pm(n) = (n!)^k \pm 1$ . The first few terms of  $S_2^+(n)$  are 2, 5, 37, 577, 14401, 518401, ... (Sloane's A020549), and  $S_2^+(n)$  is PRIME for  $n = 1, 2, 3, 4, 5, 9, 10, 11, 13, 24, 65, 76, \dots$  (Sloane's A046029). The first few terms of  $S_2^-(n)$  are 0, 3, 35, 575, 14399, 518399, ... (Sloane's A046030), but  $S_2^-(n)$  is PRIME for only  $n = 2$  since  $S_2^-(n) = (n!)^2 - 1 = (n! + 1)(n! - 1)$  for  $n > 2$ . The first few terms of  $S_3^-(n)$  are 0, 7, 215, 13823, 1727999, ..., and the first few terms of  $S_3^+(n)$  are 2, 9, 217, 13825, 1728001, ... (Sloane's A19514).

There are only four INTEGERS equal to the sum of the factorials of their digits. Such numbers are called FACTORIONS. While no factorial is a SQUARE NUMBER, D. Hoey listed sums  $< 10^{12}$  of distinct factorials which give SQUARE NUMBERS, and J. McCranie gave the one additional sum less than  $21! = 5.1 \times 10^{19}$ :

$$\begin{aligned} 0! + 1! + 2! &= 2^2 \\ 1! + 2! + 3! &= 3^2 \\ 1! + 4! &= 5^2 \\ 1! + 5! &= 11^2 \\ 4! + 5! &= 12^2 \\ 1! + 2! + 3! + 6! &= 27^2 \\ 1! + 5! + 6! &= 29^2 \\ 1! + 7! &= 71^2 \\ 4! + 5! + 7! &= 72^2 \\ 1! + 2! + 3! + 7! + 8! &= 213^2 \\ 1! + 4! + 5! + 6! + 7! + 8! &= 215^2 \\ 1! + 2! + 3! + 6! + 9! &= 603^2 \\ 1! + 4! + 8! + 9! &= 635^2 \\ 1! + 2! + 3! + 6! + 7! + 8! + 10! &= 1917^2 \end{aligned}$$

$$\begin{aligned} 1! + 2! + 3! + 7! + 8! + 9! + 10! + 11! + 12! \\ + 13! + 14! + 15! = 1183893^2 \end{aligned}$$

(Sloane's A014597). The first few values for which the alternating SUM

$$\sum_{i=1}^n (-1)^{n-i} i! \quad (36)$$

is PRIME are 3, 4, 5, 6, 7, 8, 41, 59, 61, 105, 160, ... (Sloane's A014615, Guy 1994, p. 100). The only known factorials which are products of factorial in an ARITHMETIC SEQUENCE are

$$\begin{aligned} 0!1! &= 1! \\ 1!2! &= 2! \\ 0!1!2! &= 2! \\ 6!7! &= 10! \\ 1!3!5! &= 6! \\ 1!3!5!7! &= 10! \end{aligned}$$

(Madachy 1979).

There are no identities of the form

$$n! = a_1! a_2! \dots a_r! \quad (37)$$

for  $r \geq 2$  with  $a_i \geq a_j \geq 2$  for  $i < j$  for  $n \leq 18160$  except

$$9! = 7!3!3!2! \quad (38)$$

$$10! = 7!6! = 7!5!3! \quad (39)$$

$$16! = 14!5!2! \quad (40)$$

(Guy 1994, p. 80).

There are three numbers less than 200,000 for which

$$(n-1)! + 1 \equiv 0 \pmod{n^2}, \quad (41)$$

namely 5, 13, and 563 (Le Lionnais 1983). BROWN NUMBERS are pairs  $(m, n)$  of INTEGERS satisfying the condition of BROCARD'S PROBLEM, i.e., such that

$$n! + 1 = m^2. \quad (42)$$

Only three such numbers are known: (5, 4), (11, 5), (71, 7). Erdős conjectured that these are the only three such pairs (Guy 1994, p. 193).

## Factorial Moment

$$\nu_{(r)} \equiv \sum_x x^{(r)} f(x),$$

where

$$x^{(r)} \equiv x(x-1) \cdots (x-r+1).$$

## Factorial Number

see FACTORIAL

## Factorial Prime

A PRIME of the form  $n! \pm 1$ .  $n! + 1$  is PRIME for 1, 2, 3, 11, 27, 37, 41, 73, 77, 116, 154, 320, 340, 399, 427, 872, 1477, ... (Sloane's A002981) up to a search limit 4850.  $n! - 1$  is PRIME for 3, 4, 6, 7, 12, 14, 30, 32, 33, 38, 94, 116, 324, 379, 469, 546, 974, 1963, 3507, 3610, ... (Sloane's A002982) up to a search limit of 4850.

## Factorial Sum

Sums with unity NUMERATOR and FACTORIALS in the DENOMINATOR which can be expressed analytically include

$$\sum_{i=1}^n \frac{1}{(n+i-k)!(n-i)!} = \frac{{}_2F_1(1, -n; 1+n-k; -1) - 1}{\Gamma(1+n)\Gamma(1+n-k)} \quad (1)$$

$$\sum_{i=1}^n \frac{1}{(n+i-1)!(n-i)!} = \frac{n\sqrt{\pi}}{2\Gamma(\frac{1}{2}+n)\Gamma(1+n)} \quad (2)$$

$$\sum_{i=1}^n \frac{1}{(n+i)!(n-i)!} = \frac{\sqrt{\pi}}{2\Gamma(\frac{1}{2}+n)\Gamma(1+n)} - \frac{1}{2\Gamma^2(1+n)} \quad (3)$$

$$\sum_{i=1}^n \frac{1}{(n+i+1)!(n-i)!} = \frac{\sqrt{\pi}}{2\Gamma(\frac{3}{2}+n)\Gamma(1+n)} - \frac{1}{2\Gamma(1+n)\Gamma(2+n)}, \quad (4)$$

where  ${}_2F_1(a, b; c; z)$  is a HYPERGEOMETRIC FUNCTION and  $\Gamma(z)$  is a GAMMA FUNCTION.

Sums with  $i$  in the NUMERATOR having analytic solutions include

$$\sum_{i=1}^n \frac{i}{(n+i-k)!(n-i)!} = \frac{n {}_2F_1(2, 1-n; 2-k+n; -1)}{(1-k+n)\Gamma(1+n)\Gamma(1-k+n)} \quad (5)$$

$$\sum_{i=1}^n \frac{i}{(n+i-1)!(n-i)!} = \frac{1}{2\Gamma(n)} \left[ \frac{\sqrt{\pi}}{2\Gamma(\frac{1}{2}+n)} + \frac{n}{\Gamma(1+n)} \right] \quad (6)$$

$$\sum_{i=1}^n \frac{i}{(n+i)!(n-i)!} = \frac{n}{2\Gamma^2(1+n)} \quad (7)$$

$$\sum_{i=1}^n \frac{i}{(n+i+1)!(n-i)!} = \frac{1}{2\Gamma(1+n)} \left[ \frac{1}{\Gamma(2+n)} - \frac{(n^2+3n+2)\sqrt{\pi}}{2\Gamma(\frac{3}{2}+n)} \right]. \quad (8)$$

A sum with  $i^2$  in the NUMERATOR is

$$\sum_{i=1}^n \frac{i^2}{(n+i-k)!(n-i)!} = \frac{n}{(1-k+n)(2-k+n)\Gamma(1+n)\Gamma(1-k+n)} \times [(2-k+n) {}_2F_1(2, 1-n; 2-k+n; -1) + 2(n-1) {}_2F_1(3, 2-n; 3-k+n; -1)], \quad (9)$$

where  ${}_2F_1(a, b; c; z)$  is the HYPERGEOMETRIC FUNCTION.

Sums of factorial POWERS include

$$\sum_{n=0}^{\infty} \frac{(n!)^2}{(2n)!} = \frac{4}{3} + \frac{2\pi}{9\sqrt{3}} \quad (10)$$

$$\sum_{n=0}^{\infty} \frac{(n!)^3}{(3n)!} = \int_0^1 [P(t) + Q(t) \cos^{-1} R(t)] dt, \quad (11)$$

where

$$P(t) = \frac{2(8+7t^2-7t^3)}{(4-t^2+t^3)^2} \quad (12)$$

$$Q(t) = \frac{4t(1-t)(5+t^2-t^3)}{(4-t^2+t^3)^2 \sqrt{(1-t)(4-t^2+t^3)}} \quad (13)$$

$$R(t) = 1 - \frac{1}{2}(t^2 - t^3) \quad (14)$$

(Beeler *et al.* 1972, Item 116).

#### Factoring

see FACTORIZATION

#### Factorion

A factorion is an INTEGER which is equal to the sum of FACTORIALS of its digits. There are exactly four such numbers:

$$1 = 1! \quad (1)$$

$$2 = 2! \quad (2)$$

$$145 = 1! + 4! + 5! \quad (3)$$

$$40,585 = 4! + 0! + 5! + 8! + 5! \quad (4)$$

(Gardner 1978, Madachy 1979, Pickover 1995). The factorion of an  $n$ -digit number cannot exceed  $n \cdot 9!$  digits.

see also FACTORIAL

#### Factorization

The finding of FACTORS (DIVISORS) of a given INTEGER, POLYNOMIAL, etc. Factorization is also called FACTORING.

see also FACTOR, PRIME FACTORIZATION ALGORITHMS

#### Fagnano's Point

The point of coincidence of  $P$  and  $P'$  in FAGNANO'S PROBLEM.

#### Fagnano's Problem

In a given ACUTE-angled TRIANGLE  $\triangle ABC$ , INSCRIBE another TRIANGLE whose PERIMETER is as small as possible. The answer is the PEDAL TRIANGLE of  $\triangle ABC$ .

#### References

Coxeter, H. S. M. and Greitzer, S. L. *Geometry Revisited*. Washington, DC: Math. Assoc. Amer., pp. 88-89, 1967.

#### Fagnano's Theorem

If  $P(x, y)$  and  $P(x', y')$  are two points on an ELLIPSE

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, \quad (1)$$

with ECCENTRIC ANGLES  $\phi$  and  $\phi'$  such that

$$\tan \phi \tan \phi' = \frac{b}{a} \quad (2)$$

and  $A = P(a, 0)$  and  $B = P(0, b)$ . Then

$$\text{arc } BP + \text{arc } BP' = \frac{e^2 x x'}{a}. \quad (3)$$

This follows from the identity

$$E(u, k) + E(v, k) - E(k) = k^2 \text{sn}(u, k) \text{sn}(v, k), \quad (4)$$

where  $E(u, k)$  is an incomplete ELLIPTIC INTEGRAL OF THE SECOND KIND,  $E(k)$  is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND, and  $\text{sn}(v, k)$  is a JACOBI ELLIPTIC FUNCTION. If  $P$  and  $P'$  coincide, the point where they coincide is called FAGNANO'S POINT.

#### Fair Game

A GAME which is not biased toward any player.

see also GAME, MARTINGALE

## Fairy Chess

A variation of CHESS involving a change in the form of the board, the rules of play, or the pieces used. For example, the normal rules of chess can be used but with a cylindrical or MÖBIUS STRIP connection of the edges.

see also CHESS

## References

Kraitchik, M. "Fairy Chess." §12.2 in *Mathematical Recreations*. New York: W. W. Norton, pp. 276–279, 1942.

## Fallacy

A fallacy is an incorrect result arrived at by apparently correct, though actually specious reasoning. The most common example of a mathematical fallacy is the "proof" that  $1 = 2$  as follows. Let  $a = b$ , then

$$ab = a^2$$

$$ab - b^2 = a^2 - b^2$$

$$b(a - b) = (a + b)(a - b)$$

$$b = a + b$$

$$b = 2b$$

$$1 = 2.$$

The incorrect step is division by  $a - b$  (equal to 0), which is invalid. Ball and Coxeter (1987) give other such examples in the areas of both arithmetic and geometry.

## False

A statement which is rigorously not TRUE. Regular two-valued LOGIC allows statements to be only TRUE or false, but FUZZY LOGIC treats "truth" as a continuum which can have a value between 0 and 1.

see also ALETHIC, FUZZY LOGIC, LOGIC, TRUE, TRUTH TABLE, UNDECIDABLE

## False Position Method

AN ALGORITHM for finding ROOTS which uses the point where the linear approximation crosses the axis as the next iteration and keeps the same initial point for each iteration. Using the two-point form of the line

$$y - y_1 = \frac{f(x_{n-1}) - f(x_1)}{x_{n-1} - x_1}(x_n - x_1)$$

with  $y = 0$ , using  $y_1 = f(x_1)$ , and solving for  $x_n$  therefore gives the iteration

$$x_n = x_1 - \frac{x_{n-1} - x_1}{f(x_{n-1}) - f(x_1)}f(x_1).$$

see also BRENT'S METHOD, RIDDERS' METHOD, SECANT METHOD

## Faltung (Form)

Let  $A$  and  $B$  be bilinear forms

$$A = A(x, y) = \sum \sum a_{ij} x_i y_j$$

$$B = B(x, y) = \sum \sum b_{ij} x_i y_j$$

and suppose that  $A$  and  $B$  are bounded in  $[p, p']$  with bounds  $M$  and  $N$ . Then

$$F = F(A, B) = \sum \sum f_{ij} x_i y_j,$$

where the series

$$f_{ij} = \sum_k a_{ik} b_{kj}$$

is absolutely convergent, is called the faltung of  $A$  and  $B$ .  $F$  is bounded in  $[p, p']$ , and its bound does not exceed  $MN$ .

## Faltung (Function)

see CONVOLUTION

## Fan

A SPREAD in which each node has a FINITE number of children.

see also SPREAD (TREE)

## Fano's Axiom

The three diagonal points of a COMPLETE QUADRILATERAL are never COLLINEAR.

## Fano Plane

The 2-D PROJECTIVE PLANE over  $GF(2)$  ("of order two"), illustrated above. It is a BLOCK DESIGN with  $\nu = 7$ ,  $k = 3$ ,  $\lambda = 1$ ,  $r = 3$ , and  $b = 7$ , and is also the STEINER TRIPLE SYSTEM  $S(7)$ .

The Fano plane also solves the TRANSYLVANIA LOTTERY, which picks three numbers from the INTEGERS 1–14. Using two Fano planes we can guarantee matching two by playing just 14 times as follows. Label the VERTICES of one Fano plane by the INTEGERS 1–7, the other plane by the INTEGERS 8–14. The 14 tickets to play are the 14 lines of the two planes. Then if  $(a, b, c)$  is the winning ticket, at least two of  $a, b, c$  are either in the interval  $[1, 7]$  or  $[8, 14]$ . These two numbers are on exactly one line of the corresponding plane, so one of our tickets matches them.

The Lehmers (1974) found an application of the Fano plane for factoring INTEGERS via QUADRATIC FORMS. Here, the triples of forms used form the lines of the PROJECTIVE GEOMETRY on seven points, whose planes are Fano configurations corresponding to pairs of residue classes mod 24 (Lehmer and Lehmer 1974, Guy 1975, Shanks 1985). The group of AUTOMORPHISMS (incidence-preserving BIJECTIONS) of the Fano plane is the SIMPLE GROUP OF ORDER 168 (Klein 1870).

## Far Out

A word used by Tukey to describe data points which are outside the outer FENCES.

## References

- Tukey, J. W. *Explanatory Data Analysis*. Reading, MA: Addison-Wesley, p. 44, 1977.

## Far-Out Point

For a TRIANGLE with side lengths  $a$ ,  $b$ , and  $c$ , the far-out point has TRIANGLE CENTER FUNCTION

$$\alpha = a(b^4 + c^4 - a^4 - b^2c^2).$$

As  $a : b : c$  approaches  $1 : 1 : 1$ , this point moves out along the EULER LINE to infinity.

## Farey Sequence

The Farey sequence  $F_n$  for any POSITIVE INTEGER  $n$  is the set of irreducible RATIONAL NUMBERS  $a/b$  with  $0 \leq a \leq b \leq n$  and  $(a, b) = 1$  arranged in increasing order.

$$F_1 = \left\{ \frac{0}{1}, \frac{1}{1} \right\} \quad (1)$$

$$F_2 = \left\{ \frac{0}{1}, \frac{1}{2}, \frac{1}{1} \right\} \quad (2)$$

$$F_3 = \left\{ \frac{0}{1}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{1}{1} \right\} \quad (3)$$

$$F_4 = \left\{ \frac{0}{1}, \frac{1}{4}, \frac{1}{3}, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{1}{1} \right\} \quad (4)$$

$$F_5 = \left\{ \frac{0}{1}, \frac{1}{5}, \frac{1}{4}, \frac{1}{3}, \frac{2}{5}, \frac{1}{2}, \frac{3}{5}, \frac{2}{3}, \frac{4}{5}, \frac{1}{1} \right\}. \quad (5)$$

There is always an ODD number of terms, and the middle term is always  $1/2$ . Let  $p/q$ ,  $p'/q'$ , and  $p''/q''$  be three successive terms in a Farey series. Then

$$qp' - pq' = 1 \quad (6)$$

$$\frac{p'}{q'} = \frac{p + p''}{q + q''}. \quad (7)$$

These two statements are actually equivalent.

The number of terms  $N(n)$  in the Farey sequence for the INTEGER  $n$  is

$$N(n) = 1 + \sum_{k=1}^n \phi(k) = 1 + \Phi(n), \quad (8)$$

where  $\phi(k)$  is the TOTIENT FUNCTION and  $\Phi(n)$  is the SUMMATORY FUNCTION of  $\phi(k)$ , giving 2, 3, 5, 7, 11, 13, 19, ... (Sloane's A005728). The asymptotic limit for the function  $N(n)$  is

$$N(n) \sim \frac{3n^2}{\pi^2} = 0.3039635509n^2 \quad (9)$$

(Vardi 1991, p. 155). For a method of computing a successive sequence from an existing one of  $n$  terms, insert the MEDIANT fraction  $(a + b)/(c + d)$  between terms  $a/c$  and  $b/d$  when  $c + d \leq n$  (Hardy and Wright 1979, pp. 25–26; Conway and Guy 1996).

FORD CIRCLES provide a method of visualizing the Farey sequence. The Farey sequence  $F_n$  defines a subtree of the STERN-BROCOT TREE obtained by pruning unwanted branches (Graham *et al.* 1994).

see also FORD CIRCLE, MEDIANT, RANK (SEQUENCE), STERN-BROCOT TREE

### Farey Series

see FAREY SEQUENCE

### Farkas's Lemma

The INEQUALITY  $\langle f_0, x \rangle \leq 0$  follows from

$$\langle f_1, x \rangle \leq 0, \dots, \langle f_n, x \rangle \leq 0$$

IFF there exist NONNEGATIVE numbers  $\lambda_1, \dots, \lambda_n$  with

$$\sum_{k=1}^n \lambda_k f_k = f_0.$$

This LEMMA is used in the proof of the KUHN-TUCKER THEOREM.

### Faro Shuffle

see RIFFLE SHUFFLE

### Fast Fibonacci Transform

For a general second-order recurrence equation

$$f_{n+1} = xf_n + yf_{n-1}, \quad (1)$$

define a multiplication rule on ordered pairs by

$$(A, B)(C, D) = (AD + BC + xAC, BD + yAC). \quad (2)$$

The inverse is then given by

$$(A, B)^{-1} = \frac{(-A, xA + B)}{B^2 + xAB - yA^2}, \quad (3)$$

and we have the identity

$$(f_1, yf_0)(1, 0)^n = (f_{n+1}, yf_n) \quad (4)$$

(Beeler *et al.* 1972, Item 12).

### Fast Fourier Transform

The fast Fourier transform (FFT) is a DISCRETE FOURIER TRANSFORM ALGORITHM which reduces the number of computations needed for  $N$  points from  $2N^2$  to  $2N \lg N$ , where LG is the base-2 LOGARITHM. If the function to be transformed is not harmonically related to the sampling frequency, the response of an FFT looks like a SINC FUNCTION (although the integrated POWER is still correct). ALIASING (LEAKAGE) can be reduced by APODIZATION using a TAPERING FUNCTION. However, ALIASING reduction is at the expense of broadening the spectral response.

FFTs were first discussed by Cooley and Tukey (1965), although Gauss had actually described the critical factorization step as early as 1805 (Gergkand 1969, Strang 1993). A DISCRETE FOURIER TRANSFORM can be computed using an FFT by means of the DANIELSON-LANCZOS LEMMA if the number of points  $N$  is a POWER of two. If the number of points  $N$  is not a POWER of two, a transform can be performed on sets of points corresponding to the prime factors of  $N$  which is slightly degraded in speed. An efficient real Fourier transform algorithm or a fast HARTLEY TRANSFORM (Bracewell 1965) gives a further increase in speed by approximately a factor of two. Base-4 and base-8 fast Fourier transforms use optimized code, and can be 20–30% faster than base-2 fast Fourier transforms. PRIME factorization is slow when the factors are large, but discrete Fourier transforms can be made fast for  $N = 2, 3, 4, 5, 7, 8, 11, 13$ , and 16 using the WINOGRAD TRANSFORM ALGORITHM (Press *et al.* 1992, pp. 412–413, Arndt).

Fast Fourier transform algorithms generally fall into two classes: decimation in time, and decimation in frequency. The Cooley-Tukey FFT ALGORITHM first rearranges the input elements in bit-reversed order, then builds the output transform (decimation in time). The

basic idea is to break up a transform of length  $N$  into two transforms of length  $N/2$  using the identity

$$\begin{aligned} \sum_{n=0}^{N-1} a_n e^{-2\pi i n k / N} &= \sum_{n=0}^{N/2-1} a_{2n} e^{-2\pi i (2n) k / N} \\ &\quad + \sum_{n=0}^{N/2-1} a_{2n+1} e^{-2\pi i (2n+1) k / N} \\ &= \sum_{n=0}^{N/2-1} a_n^{\text{even}} e^{-2\pi i n k / (N/2)} \\ &\quad + e^{-2\pi i k / N} \sum_{n=0}^{N/2-1} a_n^{\text{odd}} e^{-2\pi i n k / (N/2)}, \end{aligned}$$

sometimes called the DANIELSON-LANCZOS LEMMA. The easiest way to visualize this procedure is perhaps via the FOURIER MATRIX.

The Sande-Tukey ALGORITHM (Stoer and Burlisch 1980) first transforms, then rearranges the output values (decimation in frequency).

#### Fatou's Theorems

Let  $f(\theta)$  be LEBESGUE INTEGRABLE and let

$$f(r, \theta) = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(t) \frac{1 - r^2}{1 - 2r \cos(t - \theta) + r^2} dt \quad (1)$$

be the corresponding POISSON INTEGRAL. Then ALMOST EVERYWHERE in  $-\pi \leq \theta \leq \pi$ ,

$$\lim_{r \rightarrow 0^-} f(r, \theta) = f(\theta). \quad (2)$$

Let

$$F(z) = c_0 + c_1 z + c_2 z^2 + \dots + c_n z^n + \dots \quad (3)$$

be regular for  $|z| < 1$ , and let the integral

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} |F(re^{i\theta})|^2 d\theta \quad (4)$$

be bounded for  $r < 1$ . This condition is equivalent to the convergence of

$$|c_0|^2 + |c_1|^2 + \dots + |c_n|^2 + \dots \quad (5)$$

Then almost everywhere in  $-\pi \leq \theta \leq \pi$ ,

$$\lim_{r \rightarrow 0^-} F(re^{i\theta}) = F(e^{i\theta}). \quad (6)$$

Furthermore,  $F(e^{i\theta})$  is measurable,  $|F(e^{i\theta})|^2$  is LEBESGUE INTEGRABLE, and the FOURIER SERIES of  $F(e^{i\theta})$  is given by writing  $z = e^{i\theta}$ .

#### Faulhaber's Formula

In a 1631 edition of *Academiae Algebrae*, J. Faulhaber published the general formula for the SUM of  $p$ th POWERS of the first  $n$  POSITIVE INTEGERS,

$$\sum_{k=1}^n k^p = \frac{1}{p+1} \sum_{i=1}^{p+1} (-1)^{\delta_{ip}} \binom{p+1}{i} B_{p+1-i} n^i, \quad (1)$$

where  $\delta_{ip}$  is the KRONECKER DELTA,  $\binom{n}{i}$  is a BINOMIAL COEFFICIENT, and  $B_i$  is the  $i$ th BERNOULLI NUMBER. Computing the sums for  $p = 1, \dots, 10$  gives

$$\sum_{k=1}^n k = \frac{1}{2}(n^2 + n) \quad (2)$$

$$\sum_{k=1}^n k^2 = \frac{1}{6}(2n^3 + 3n^2 + n) \quad (3)$$

$$\sum_{k=1}^n k^3 = \frac{1}{4}(n^4 + 2n^3 + n^2) \quad (4)$$

$$\sum_{k=1}^n k^4 = \frac{1}{30}(6n^5 + 15n^4 + 10n^3 - n) \quad (5)$$

$$\sum_{k=1}^n k^5 = \frac{1}{12}(2n^6 + 6n^5 + 5n^4 - n^2) \quad (6)$$

$$\sum_{k=1}^n k^6 = \frac{1}{42}(6n^7 + 21n^6 + 21n^5 - 7n^3 + n) \quad (7)$$

$$\sum_{k=1}^n k^7 = \frac{1}{24}(3n^8 + 12n^7 + 14n^6 - 7n^4 + 2n^2) \quad (8)$$

$$\sum_{k=1}^n k^8 = \frac{1}{90}(10n^9 + 45n^8 + 60n^7 - 42n^5 + 20n^3 - 3n) \quad (9)$$

$$\sum_{k=1}^n k^9 = \frac{1}{20}(2n^{10} + 10n^9 + 15n^8 - 14n^6 + 10n^4 - 3n^2) \quad (10)$$

$$\sum_{k=1}^n k^{10} = \frac{1}{66}(6n^{11} + 33n^{10} + 55n^9 - 66n^7 + 66n^5 - 33n^3 + 5n). \quad (11)$$

#### Favard Constants

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Let  $T_n(x)$  be an arbitrary trigonometric POLYNOMIAL

$$T_n(x) = \frac{1}{2}a_0 + \left\{ \sum_{k=1}^n [a_k \cos(kx) + b_k \sin(kx)] \right\},$$

where the COEFFICIENTS are real. Let the  $r$ th derivative of  $T_n(x)$  be bounded in  $[-1, 1]$ , then there exists a POLYNOMIAL  $T_n(x)$  for which

$$|f(x) - T_n(x)| \leq \frac{K_r}{(n+1)^r},$$

for all  $x$ , where  $K_r$  is the  $r$ th Favard constant, which is the smallest constant possible.

$$K_r = \frac{4}{\pi} \sum_{k=0}^{\infty} \left[ \frac{(-1)^k}{2k+1} \right]^{r+1}.$$

These can be expressed by

$$K_r = \begin{cases} \frac{4}{\pi} \lambda(r+1) & \text{for } r \text{ odd} \\ \frac{4}{\pi} \beta(r+1) & \text{for } r \text{ even,} \end{cases}$$

where  $\lambda$  is the DIRICHLET LAMBDA FUNCTION and  $\beta$  is the DIRICHLET BETA FUNCTION. Explicitly,

$$\begin{aligned} K_0 &= 1 \\ K_1 &= \frac{1}{2}\pi \\ K_2 &= \frac{1}{8}\pi^2 \\ K_3 &= \frac{1}{24}\pi^3. \end{aligned}$$

#### Feigenbaum Constant

A universal constant for functions approaching CHAOS via period doubling. It was discovered by Feigenbaum in 1975 and demonstrated rigorously by Lanford (1982) and Collet and Eckmann (1979, 1980). The Feigenbaum constant  $\delta$  characterizes the geometric approach of the bifurcation parameter to its limiting value. Let  $\mu_k$  be the point at which a period  $2^k$  cycle becomes unstable.

Denote the converged value by  $\mu_\infty$ . Assuming geometric convergence, the difference between this value and  $\mu_k$  is denoted

$$\lim_{k \rightarrow \infty} \mu_\infty - \mu_k = \frac{\Gamma}{\delta^k}, \quad (1)$$

where  $\Gamma$  is a constant and  $\delta$  is a constant  $> 1$ . Solving for  $\delta$  gives

$$\delta \equiv \lim_{n \rightarrow \infty} \frac{\mu_{n+1} - \mu_n}{\mu_{n+2} - \mu_{n+1}} \quad (2)$$

(Rasband 1990, p. 23). For the LOGISTIC EQUATION,

$$\delta = 4.669216091\dots \quad (3)$$

$$\Gamma = 2.637\dots \quad (4)$$

$$\mu_\infty = 3.5699456\dots \quad (5)$$

Amazingly, the Feigenbaum constant  $\delta \approx 4.669$  is “universal” (i.e., the same) for all 1-D MAPS  $f(x)$  if  $f(x)$  has a single locally quadratic MAXIMUM. More specifically, the Feigenbaum constant is universal for 1-D MAPS if the SCHWARZIAN DERIVATIVE

$$D_{\text{Schwarzian}} \equiv \frac{f'''(x)}{f'(x)} - \frac{3}{2} \left[ \frac{f''(x)}{f'(x)} \right]^2 \quad (6)$$

is NEGATIVE in the bounded interval (Tabor 1989, p. 220). Examples of maps which are universal include the HÉNON MAP, LOGISTIC MAP, LORENZ SYSTEM, Navier-Stokes truncations, and sine map  $x_{n+1} = a \sin(\pi x_n)$ . The value of the Feigenbaum constant can be computed explicitly using functional group renormalization theory. The universal constant also occurs in phase transitions in physics and, curiously, is very nearly equal to

$$\pi + \tan^{-1}(e^\pi) = 4.669201932\dots \quad (7)$$

The CIRCLE MAP is *not* universal, and has a Feigenbaum constant of  $\delta \approx 2.833$ . For an AREA-PRESERVING 2-D MAP with

$$x_{n+1} = f(x_n, y_n) \quad (8)$$

$$y_{n+1} = g(x_n, y_n), \quad (9)$$

the Feigenbaum constant is  $\delta = 0.7210978\dots$  (Tabor 1989, p. 225). For a function of the form

$$f(x) = 1 - a|x|^n \quad (10)$$

with  $a$  and  $n$  constant and  $n$  an INTEGER, the Feigenbaum constant for various  $n$  is given in the following table (Briggs 1991, Briggs *et al.* 1991), which updates the values in Tabor (1989, p. 225).

$n$	$\delta$
2	5.9679
4	7.2846
6	8.3494
8	9.2962

An additional constant  $\alpha$ , defined as the separation of adjacent elements of PERIOD DOUBLED ATTRACTORS from one double to the next, has a value

$$\lim_{n \rightarrow \infty} \frac{d_n}{d_{n+1}} \equiv -\alpha = -2.502907875\dots \quad (11)$$

for “universal” maps (Rasband 1990, p. 37). This value may be approximated from functional group renormalization theory to the zeroth order by

$$1 - \alpha^{-1} = \frac{1 - \alpha^{-2}}{[1 - \alpha^{-2}(1 - \alpha^{-1})]^2}, \quad (12)$$

which, when the QUINTIC EQUATION is numerically solved, gives  $\alpha = -2.48634\dots$ , only 0.7% off from the actual value (Feigenbaum 1988).

**Feigenbaum Function**

Consider an arbitrary 1-D MAP

$$x_{n+1} = F(x_n) \quad (1)$$

at the onset of CHAOS. After a suitable rescaling, the Feigenbaum function

$$g(x) = \lim_{n \rightarrow \infty} \frac{1}{F^{(2^n)}(0)} F^{(2^n)}(x F^{(2^n)}(0)) \quad (2)$$

is obtained. This function satisfies

$$g(g(x)) = -\frac{1}{\alpha} g(\alpha x), \quad (3)$$

with  $\alpha = 2.50290\dots$ , a quantity related to the FEIGENBAUM CONSTANT.

Szegő, G. *Orthogonal Polynomials*, 4th ed. Providence, RI: Amer. Math. Soc., p. 12, 1975.

**Fejes Tóth's Problem**

How can  $n$  points be distributed on a UNIT SPHERE such that they maximize the minimum distance between any pair of points? In 1943, Fejes Tóth proved that for  $N$  points, there always exist two points whose distance  $d$  is

$$d \leq \sqrt{4 - \csc^2 \left[ \frac{\pi N}{6(N-2)} \right]},$$

and that the limit is exact for  $N = 3, 4, 6$ , and 12.

For two points, the points should be at opposite ends of a DIAMETER. For four points, they should be placed at the VERTICES of an inscribed TETRAHEDRON. There is no best solution for five points since the distance cannot be reduced below that for six points. For six points, they should be placed at the VERTICES of an inscribed OCTAHEDRON. For seven points, the best solution is four equilateral spherical triangles with angles of  $80^\circ$ . For eight points, the best dispersal is *not* the VERTICES of the inscribed CUBE, but of a square ANTIPRISM with equal EDGES. The solution for nine points is eight equilateral spherical triangles with angles of  $\cos^{-1}(1/4)$ . For 12 points, the solution is an inscribed ICOSAEDRON.

The general problem has not been solved.

**Feller's Coin-Tossing Constants**

see COIN TOSSING

**Feller-Lévy Condition**

Given a sequence of independent random variates  $X_1, X_2, \dots$ , if  $\sigma_k^2 = \text{var}(X_k)$  and

$$\rho_n^2 \equiv \max_{k \leq n} \left( \frac{\sigma_k^2}{s_n^2} \right),$$

then

$$\lim_{n \rightarrow \infty} \rho_n^2 = 0.$$

This means that if the LINDBERG CONDITION holds for the sequence of variates  $X_1, \dots$ , then the VARIANCE of an individual term in the sum  $S_n$  of  $X_k$  is asymptotically negligible. For such sequences, the LINDBERG CONDITION is NECESSARY as well as SUFFICIENT for the LINDBERG-FELLER CENTRAL LIMIT THEOREM to hold.

**Ferguson-Forcade Algorithm**

A practical algorithm for determining if there exist integers  $a_i$  for given real numbers  $x_i$  such that

$$a_1x_1 + a_2x_2 + \dots + a_nx_n = 0,$$

or else establish bounds within which no such INTEGER RELATION can exist (Ferguson and Forcade 1979). A nonrecursive variant of the original algorithm was subsequently devised by Ferguson (1987). The Ferguson-Forcade algorithm has shown that there are no algebraic equations of degree  $\leq 8$  with integer coefficients having Euclidean norms below certain bounds for  $e/\pi$ ,  $e + \pi$ ,  $\ln \pi$ ,  $\gamma$ ,  $e^\gamma$ ,  $\gamma/e$ ,  $\gamma/\pi$ , and  $\ln \gamma$ , where  $e$  is the base for the NATURAL LOGARITHM,  $\pi$  is PI, and  $\gamma$  is the EULER-MASCHERONI CONSTANT (Bailey 1988).

Constant	Bound
$e/\pi$	$6.1030 \times 10^{14}$
$e + \pi$	$2.2753 \times 10^{18}$
$\ln \pi$	$8.7697 \times 10^9$
$\gamma$	$3.5739 \times 10^9$
$e^\gamma$	$1.6176 \times 10^{17}$
$\gamma/e$	$1.8440 \times 10^{11}$
$\gamma/\pi$	$6.5403 \times 10^9$
$\ln \gamma$	$2.6881 \times 10^{10}$

### Fermat's Factorization Method

Given a number  $n$ , look for INTEGERS  $x$  and  $y$  such that  $n = x^2 - y^2$ . Then

$$n = (x - y)(x + y) \quad (1)$$

and  $n$  is factored. Any ODD NUMBER can be represented in this form since then  $n = ab$ ,  $a$  and  $b$  are ODD, and

$$a = x + y \quad (2)$$

$$b = x - y. \quad (3)$$

Adding and subtracting,

$$a + b = 2x \quad (4)$$

$$a - b = 2y, \quad (5)$$

so solving for  $x$  and  $y$  gives

$$x = \frac{1}{2}(a + b) \quad (6)$$

$$y = \frac{1}{2}(a - b). \quad (7)$$

Therefore,

$$x^2 - y^2 = \frac{1}{4}[(a + b)^2 - (a - b)^2] = ab. \quad (8)$$

As the first trial for  $x$ , try  $x_1 \lceil \sqrt{n} \rceil$ , where  $\lceil x \rceil$  is the CEILING FUNCTION. Then check if

$$\Delta x_1 = x_1^2 - n \quad (9)$$

is a SQUARE NUMBER. There are only 22 combinations of the last two digits which a SQUARE NUMBER can assume, so most combinations can be eliminated. If  $\Delta x_1$  is not a SQUARE NUMBER, then try

$$x_2 = x_1 + 1, \quad (10)$$

so

$$\begin{aligned} \Delta x_2 &= x_2^2 - n = (x_1 + 1)^2 - n = x_1^2 + 2x_1 + 1 - n \\ &= \Delta x_1 + 2x_1 + 1. \end{aligned} \quad (11)$$

Continue with

$$\begin{aligned} \Delta x_3 &= x_3^2 - n = (x_2 + 1)^2 - n = x_2^2 + 2x_2 + 1 - n \\ &= \Delta x_2 + 2x_2 + 1 = \Delta x_1 + 2x_1 + 3, \end{aligned} \quad (12)$$

so subsequent differences are obtained simply by adding two.

Maurice Kraitchik sped up the ALGORITHM by looking for  $x$  and  $y$  satisfying

$$x^2 \equiv y^2 \pmod{n}, \quad (13)$$

i.e.,  $n|(x^2 - y^2)$ . This congruence has uninteresting solutions  $x \equiv \pm y \pmod{n}$  and interesting solutions

$x \not\equiv \pm y \pmod{n}$ . It turns out that if  $n$  is ODD and DIVISIBLE by at least two different PRIMES, then at least half of the solutions to  $x^2 \equiv y^2 \pmod{n}$  with  $xy$  CO-PRIME to  $n$  are interesting. For such solutions,  $(n, x - y)$  is neither  $n$  nor 1 and is therefore a nontrivial factor of  $n$  (Pomerance 1996). This ALGORITHM can be used to prove primality, but is not practical. In 1931, Lehmer and Powers discovered how to search for such pairs using CONTINUED FRACTIONS. This method was improved by Morrison and Brillhart (1975) into the CONTINUED FRACTION FACTORIZATION ALGORITHM, which was the fastest ALGORITHM in use before the QUADRATIC SIEVE FACTORIZATION METHOD was developed.

### Fermat's Last Theorem

A theorem first proposed by Fermat in the form of a note scribbled in the margin of his copy of the ancient Greek text *Arithmetica* by Diophantus. The scribbled note was discovered posthumously, and the original is now lost. However, a copy was preserved in a book published by Fermat's son. In the note, Fermat claimed to have discovered a proof that the DIOPHANTINE EQUATION  $x^n + y^n = z^n$  has no INTEGER solutions for  $n > 2$ .

The full text of Fermat's statement, written in Latin, reads "Cubum autem in duos cubos, aut quadratoquadratum in duos quadratoquadratos & generaliter nullam in infinitum ultra quadratum potestatem in duos eiusdem nominis fas est diuidere cuius rei demonstrationem mirabilem sane detexi. Hanc marginis exiguitas non caperet." In translation, "It is impossible for a cube to be the sum of two cubes, a fourth power to be the sum of two fourth powers, or in general for any number that is a power greater than the second to be the sum of two like powers. I have discovered a truly marvelous demonstration of this proposition that this margin is too narrow to contain."

As a result of Fermat's marginal note, the proposition that the DIOPHANTINE EQUATION

$$x^n + y^n = z^n, \quad (1)$$

where  $x, y, z$ , and  $n$  are INTEGERS, has no NONZERO solutions for  $n > 2$  has come to be known as Fermat's Last Theorem. It was called a "THEOREM" on the strength of Fermat's statement, despite the fact that no other mathematician was able to prove it for hundreds of years.

Note that the restriction  $n > 2$  is obviously necessary since there are a number of elementary formulas for generating an infinite number of PYTHAGOREAN TRIPLES  $(x, y, z)$  satisfying the equation for  $n = 2$ ,

$$x^2 + y^2 = z^2. \quad (2)$$

A first attempt to solve the equation can be made by attempting to factor the equation, giving

$$(z^{n/2} + y^{n/2})(z^{n/2} - y^{n/2}) = x^n. \quad (3)$$

Since the product is an exact POWER,

$$\begin{cases} z^{n/2} + y^{n/2} = 2^{n-1}p^n \\ z^{n/2} - y^{n/2} = 2q^n \end{cases} \quad \text{or} \quad \begin{cases} z^{n/2} + y^{n/2} = 2p^n \\ z^{n/2} - y^{n/2} = 2^{n-1}q^n. \end{cases} \quad (4)$$

Solving for  $y$  and  $z$  gives

$$\begin{cases} z^{n/2} = 2^{n-2}p^n + q^n \\ y^{n/2} = 2^{n-2}p^n - q^n \end{cases} \quad \text{or} \quad \begin{cases} z^{n/2} = p^n + 2^{n-2}q^n \\ y^{n/2} = p^n - 2^{n-2}q^n, \end{cases} \quad (5)$$

which give

$$\begin{cases} z = (2^{n-2}p^n + q^n)^{2/n} \\ y = (2^{n-2}p^n - q^n)^{2/n} \end{cases} \quad \text{or} \quad \begin{cases} z = (p^n + 2^{n-2}q^n)^{2/n} \\ y = (p^n - 2^{n-2}q^n)^{2/n}. \end{cases} \quad (6)$$

However, since solutions to these equations in RATIONAL NUMBERS are no easier to find than solutions to the original equation, this approach unfortunately does not provide any additional insight.

It is sufficient to prove Fermat's Last Theorem by considering PRIME POWERS only, since the arguments can otherwise be written

$$(x^m)^p + (y^m)^p = (z^m)^p, \quad (7)$$

so redefining the arguments gives

$$x^p + y^p = z^p. \quad (8)$$

The so-called "first case" of the theorem is for exponents which are RELATIVELY PRIME to  $x$ ,  $y$ , and  $z$  ( $p \nmid x, y, z$ ) and was considered by Wieferich. Sophie Germain proved the first case of Fermat's Last Theorem for any ODD PRIME  $p$  when  $2p + 1$  is also a PRIME. Legendre subsequently proved that if  $p$  is a PRIME such that  $4p + 1$ ,  $8p + 1$ ,  $10p + 1$ ,  $14p + 1$ , or  $16p + 1$  is also a PRIME, then the first case of Fermat's Last Theorem holds for  $p$ . This established Fermat's Last Theorem for  $p < 100$ . In 1849, Kummer proved it for all REGULAR PRIMES and COMPOSITE NUMBERS of which they are factors (Vandiver 1929, Ball and Coxeter 1987).

Kummer's attack led to the theory of IDEALS, and Vandiver developed VANDIVER'S CRITERIA for deciding if

a given IRREGULAR PRIME satisfies the theorem. Genocchi (1852) proved that the first case is true for  $p$  if  $(p, p - 3)$  is not an IRREGULAR PAIR. In 1858, Kummer showed that the first case is true if either  $(p, p - 3)$  or  $(p, p - 5)$  is an IRREGULAR PAIR, which was subsequently extended to include  $(p, p - 7)$  and  $(p, p - 9)$  by Mirimanoff (1905). Wieferich (1909) proved that if the equation is solved in integers RELATIVELY PRIME to an ODD PRIME  $p$ , then

$$2^{p-1} \equiv 1 \pmod{p^2}. \quad (9)$$

(Ball and Coxeter 1987). Such numbers are called WIEFERICH PRIMES. Mirimanoff (1909) subsequently showed that

$$3^{p-1} \equiv 1 \pmod{p^2} \quad (10)$$

must also hold for solutions RELATIVELY PRIME to an ODD PRIME  $p$ , which excludes the first two WIEFERICH PRIMES 1093 and 3511. Vandiver (1914) showed

$$5^{p-1} \equiv 1 \pmod{p^2}, \quad (11)$$

and Frobenius extended this to

$$11^{p-1}, 17^{p-1} \equiv 1 \pmod{p^2}. \quad (12)$$

It has also been shown that if  $p$  were a PRIME of the form  $6x - 1$ , then

$$7^{p-1}, 13^{p-1}, 19^{p-1} \equiv 1 \pmod{p^2}, \quad (13)$$

which raised the smallest possible  $p$  in the "first case" to 253,747,889 by 1941 (Rosser 1941). Granville and Monagan (1988) showed if there exists a PRIME  $p$  satisfying Fermat's Last Theorem, then

$$q^{p-1} \equiv 1 \pmod{p^2} \quad (14)$$

for  $q = 5, 7, 11, \dots, 71$ . This establishes that the first case is true for all PRIME exponents up to 714,591,416,091,398 (Vardi 1991).

The "second case" of Fermat's Last Theorem (for  $p \mid x, y, z$ ) proved harder than the first case.

Euler proved the general case of the theorem for  $n = 3$ , Fermat  $n = 4$ , Dirichlet and Lagrange  $n = 5$ . In 1832, Dirichlet established the case  $n = 14$ . The  $n = 7$  case was proved by Lamé (1839), using the identity

$$\begin{aligned} (X + Y + Z)^7 - (X^7 + Y^7 + Z^7) \\ = 7(X + Y)(X + Z)(Y + Z) \\ \times [(X^2 + Y^2 + Z^2 + XY + XZ + YZ)^2 \\ + XYZ(X + Y + Z)]. \end{aligned} \quad (15)$$

Although some errors were present in this proof, these were subsequently fixed by Lebesgue (1840). Much additional progress was made over the next 150 years, but

no completely general result had been obtained. Buoyed by false confidence after his proof that  $P_1$  is TRANSCENDENTAL, the mathematician Lindemann proceeded to publish several proofs of Fermat's Last Theorem, all of them invalid (Bell 1937, pp. 464–465). A prize of 100,000 German marks (known as the Wolfskel Prize) was also offered for the first valid proof (Ball and Coxeter 1987, p. 72).

A recent false alarm for a general proof was raised by Y. Miyaoka (Cipra 1988) whose proof, however, turned out to be flawed. Other attempted proofs among both professional and amateur mathematicians are discussed by vos Savant (1993), although vos Savant erroneously claims that work on the problem by Wiles (discussed below) is invalid. By the time 1993 rolled around, the general case of Fermat's Last Theorem had been shown to be true for all exponents up to  $4 \times 10^6$  (Cipra 1993). However, given that a proof of Fermat's Last Theorem requires truth for *all* exponents, proof for any finite number of exponents does not constitute any significant progress towards a proof of the general theorem (although the fact that no counterexamples were found for this many cases is highly suggestive).

In 1993, a bombshell was dropped. In that year, the general theorem was partially proven by Andrew Wiles (Cipra 1993, Stewart 1993) by proving the SEMISTABLE case of the TANIYAMA-SHIMURA CONJECTURE. Unfortunately, several holes were discovered in the proof shortly thereafter when Wiles' approach via the TANIYAMA-SHIMURA CONJECTURE became hung up on properties of the SELMER GROUP using a tool called an "Euler system." However, the difficulty was circumvented by Wiles and R. Taylor in late 1994 (Cipra 1994, 1995ab) and published in Taylor and Wiles (1995) and Wiles (1995). Wiles' proof succeeds by (1) replacing ELLIPTIC CURVES with Galois representations, (2) reducing the problem to a CLASS NUMBER FORMULA, (3) proving that FORMULA, and (4) tying up loose ends that arise because the formalisms fail in the simplest degenerate cases (Cipra 1995a).

The proof of Fermat's Last Theorem marks the end of a mathematical era. Since virtually all of the tools which were eventually brought to bear on the problem had yet to be invented in the time of Fermat, it is interesting to speculate about whether he actually was in possession of an elementary proof of the theorem. Judging by the temerity with which the problem resisted attack for so long, Fermat's alleged proof seems likely to have been illusionary.

### Fermat's Lesser Theorem

see FERMAT'S LITTLE THEOREM

### Fermat's Little Theorem

If  $p$  is a PRIME number and  $a$  a NATURAL NUMBER, then

$$a^p \equiv a \pmod{p}. \quad (1)$$

Furthermore, if  $p \nmid a$  ( $p$  does not divide  $a$ ), then there exists some smallest exponent  $d$  such that

$$a^d - 1 \equiv 0 \pmod{p} \quad (2)$$

and  $d$  divides  $p - 1$ . Hence,

$$a^{p-1} - 1 \equiv 0 \pmod{p}. \quad (3)$$

This is a generalization of the CHINESE HYPOTHESIS and a special case of EULER'S THEOREM. It is sometimes called FERMAT'S PRIMALITY TEST and is a NECESSARY but not SUFFICIENT test for primality. Although it was presumably proved (but suppressed) by Fermat, the first proof was published by Euler in 1749.

The theorem is easily proved using mathematical INDUCTION. Suppose  $p \nmid a^p - a$ . Then examine

$$(a + 1)^p - (a + 1). \quad (4)$$

From the BINOMIAL THEOREM,

$$(a+1)^p = a^p + \binom{p}{1}a^{p-1} + \binom{p}{2}a^{p-2} + \dots + \binom{p}{p-1}a + 1. \quad (5)$$

Rewriting,

$$(a+1)^p - a^p - 1 = \binom{p}{1}a^{p-1} + \binom{p}{2}a^{p-2} + \dots + \binom{p}{p-1}a. \quad (6)$$

But  $p$  divides the right side, so it also divides the left side. Combining with the induction hypothesis gives that  $p$  divides the sum

$$[(a+1)^p - a^p - 1] + (a^p - a) = (a+1)^p - (a+1), \quad (7)$$

as assumed, so the hypothesis is true for any  $a$ . The theorem is sometimes called FERMAT'S SIMPLE THEOREM. WILSON'S THEOREM follows as a COROLLARY of Fermat's Little Theorem.

Fermat's little theorem shows that, if  $p$  is PRIME, there does not exist a base  $a < p$  with  $(a, p) = 1$  such that  $a^{p-1} - 1$  possesses a nonzero residue modulo  $p$ . If such base  $a$  exists,  $p$  is therefore guaranteed to be composite. However, the lack of a nonzero residue in Fermat's little theorem does *not* guarantee that  $p$  is PRIME. The property of unambiguously certifying composite numbers while passing some PRIMES make Fermat's little theorem a COMPOSITENESS TEST which is sometimes called the FERMAT COMPOSITENESS TEST. COMPOSITE NUMBERS known as FERMAT PSEUDOPRIMES (or sometimes simply "PSEUDOPRIMES") have zero residue for some  $a$ s and so are not identified as composite. Worse still, there exist numbers known as CARMICHAEL NUMBERS (the smallest of which is 561) which give zero residue for *any* choice of the base  $a$  RELATIVELY PRIME to  $p$ . However, FERMAT'S LITTLE THEOREM CONVERSE provides a criterion for certifying the primality of a number.

A number satisfying Fermat's little theorem for some nontrivial base and which is not known to be composite is called a PROBABLE PRIME. A table of the smallest PSEUDOPRIMES  $P$  for the first 100 bases  $a$  follows (Sloane's A007535).

<i>a</i>	<i>P</i>	<i>a</i>	<i>P</i>	<i>a</i>	<i>P</i>	<i>a</i>	<i>P</i>	<i>a</i>	<i>P</i>

#### Fermat's Little Theorem Converse

The converse of FERMAT'S LITTLE THEOREM is also known as LEHMER'S THEOREM. It states that, if an INTEGER  $x$  is PRIME to  $m$  and  $x^{m-1} \equiv 1 \pmod{m}$  and there is no INTEGER  $e < m-1$  for which  $x^e \equiv 1 \pmod{m}$ , then  $m$  is PRIME. Here,  $x$  is called a WITNESS to the primality of  $m$ . This theorem is the basis for the PRATT PRIMALITY CERTIFICATE.

#### Fermat-Lucas Number

A number of the form  $2^n + 1$  obtained by setting  $x = 1$  in a FERMAT-LUCAS POLYNOMIAL. The first few are 3, 5, 9, 17, 33, ... (Sloane's A000051).

see also FERMAT NUMBER (LUCAS)

#### References

- Sloane, N. J. A. Sequence A000051/M0717 in "An On-Line Version of the Encyclopedia of Integer Sequences."

#### Fermat Number

A BINOMIAL NUMBER of the form  $F_n = 2^{2^n} + 1$ . The first few for  $n = 0, 1, 2, \dots$  are 3, 5, 17, 257, 65537, 4294967297, ... (Sloane's A000215). The number of DIGITS for a Fermat number is

$$D(n) = \lfloor \log(2^{2^n} + 1) \rfloor + 1 \approx \lfloor \log(2^{2^n}) \rfloor + 1 \\ = \lfloor 2^n \log 2 + 1 \rfloor. \quad (1)$$

Being a Fermat number is the NECESSARY (but not SUFFICIENT) form a number

$$N_n \equiv 2^n + 1 \quad (2)$$

must have in order to be PRIME. This can be seen by noting that if  $N_n = 2^n + 1$  is to be PRIME, then  $n$  cannot have any ODD factors  $b$  or else  $N_n$  would be a factorable number of the form

$$2^n + 1 = (2^a)^b + 1 \\ = (2^a + 1)[2^{a(b-1)} - 2^{a(b-2)} + 2^{a(b-3)} - \dots + 1]. \quad (3)$$

Therefore, for a PRIME  $N_n$ ,  $n$  must be a POWER of 2.

Fermat conjectured in 1650 that every Fermat number is PRIME, but only COMPOSITE Fermat numbers  $F_n$  are known for  $n \geq 5$ . Eisenstein (1844) proposed as a problem the proof that there are an infinite number of Fermat primes (Ribenoim 1996, p. 88), but this has not yet been achieved. An anonymous writer proposed that numbers of the form  $2^2 + 1$ ,  $2^{2^2} + 1$ ,  $2^{2^{2^2}} + 1$  were PRIME. However, this conjecture was refuted when Selfridge (1953) showed that

$$F_{16} = 2^{2^{16}} + 1 = 2^{2^{2^{2^2}}} + 1 \quad (4)$$

is COMPOSITE (Ribenoim 1996, p. 88). Numbers of the form  $a^{2^n} + b^{2^n}$  are called generalized Fermat numbers (Ribenoim 1996, pp. 359–360).

Fermat numbers satisfy the RECURRENCE RELATION

$$F_m = F_0 F_1 \cdots F_{m-1} + 2. \quad (5)$$

$F_n$  can be shown to be PRIME iff it satisfies PÉPIN'S TEST

$$3^{(F_n-1)/2} \equiv -1 \pmod{F_n}. \quad (6)$$

## PÉPIN'S THEOREM

$$3^{2^{2^n-1}} \equiv -1 \pmod{F_n} \quad (7)$$

is also NECESSARY and SUFFICIENT.

In 1770, Euler showed that any FACTOR of  $F_n$  must have the form

$$2^{n+1}K + 1, \quad (8)$$

where  $K$  is a POSITIVE INTEGER. In 1878, Lucas increased the exponent of 2 by one, showing that FACTORS of Fermat numbers must be of the form

$$2^{n+2}L + 1. \quad (9)$$

If

$$F = p_1 p_2 \cdots p_r \quad (10)$$

is the factored part of  $F_n = FC$  (where  $C$  is the cofactor to be tested for primality), compute

$$A \equiv 3^{F_n-1} \pmod{F_n} \quad (11)$$

$$B \equiv 3^{F-1} \pmod{F_n} \quad (12)$$

$$R \equiv A - B \pmod{C}. \quad (13)$$

Then if  $R \equiv 0$ , the cofactor is a PROBABLE PRIME to the base  $3^F$ ; otherwise  $C$  is COMPOSITE.

In order for a POLYGON to be circumscribed about a CIRCLE (i.e., a CONSTRUCTIBLE POLYGON), it must have a number of sides  $N$  given by

$$N = 2^k F_0 \cdots F_n, \quad (14)$$

where the  $F_n$  are *distinct* Fermat primes. This is equivalent to the statement that the trigonometric functions  $\sin(k\pi/N)$ ,  $\cos(k\pi/N)$ , etc., can be computed in terms of finite numbers of additions, multiplications, and square root extractions iff  $N$  is of the above form. The only known Fermat PRIMES are

$$F_0 = 3$$

$$F_1 = 5$$

$$F_2 = 17$$

$$F_3 = 257$$

$$F_4 = 65537$$

and it seems unlikely that any more exist.

Factoring Fermat numbers is extremely difficult as a result of their large size. In fact, only  $F_5$  to  $F_{11}$  have been

complete factored, as summarized in the following table. Written out explicitly, the complete factorizations are

$$F_5 = 641 \cdot 6700417$$

$$F_6 = 274177 \cdot 67280421310721$$

$$F_7 = 59649589127497217 \cdot 5704689200685129054721$$

$$F_8 = 1238926361552897 \cdot 93461639715357977769163 \cdots \\ \cdots 558199606896584051237541638188580280321$$

$$F_9 = 2424833 \cdot 74556028256478842083373957362004 \cdots \\ \cdots 54918783366342657 \cdot P99$$

$$F_{10} = 45592577 \cdot 6487031809 \cdot 46597757852200185 \cdots \\ \cdots 43264560743076778192897 \cdot P252$$

$$F_{11} = 319489 \cdot 974849 \cdot 167988556341760475137 \\ \cdot 3560841906445833920513 \cdot P564.$$

Here, the final large PRIME is not explicitly given since it can be computed by dividing  $F_n$  by the other given factors.

$F_n$	Digits	Facts.	Digits	Reference
5	10	2	3, 7	Euler 1732
6	20	2	6, 14	Landry 1880
7	39	2	7, 22	Morrison and Brillhart 1975
8	78	2	16, 62	Brent and Pollard 1981
9	155	3	7, 49, 99	Manasse and Lenstra (In Cipra 1993)
10	309	4	8, 10, 40, 252	Brent 1995
11	617	5	6, 6, 21, 22, 564	Brent 1988

Tables of known factors of Fermat numbers are given by Keller (1983), Brillhart *et al.* (1988), Young and Buell (1988), Riesel (1994), and Pomerance (1996). Young and Buell (1988) discovered that  $F_{20}$  is COMPOSITE, and Crandall *et al.* (1995) that  $F_{22}$  is COMPOSITE. A current list of the known factors of Fermat numbers is maintained by Keller, and reproduced in the form of a *Mathematica*® notebook by Weisstein. In these tables, since all factors are of the form  $k2^n + 1$ , the known factors are expressed in the concise form  $(k, n)$ . The number of factors for Fermat numbers  $F_n$  for  $n = 0, 1, 2, \dots$  are 1, 1, 1, 1, 1, 2, 2, 2, 2, 3, 4, 5,  $\dots$

### Fermat Number (Lucas)

A number of the form  $2^n - 1$  obtained by setting  $x = 1$  in a FERMAT POLYNOMIAL is called a MERSENNE NUMBER.

see also FERMAT-LUCAS NUMBER, MERSENNE NUMBER

### Fermat Point

Also known as the first ISOGONIC CENTER and the TORRICELLI POINT. In a given ACUTE TRIANGLE  $\triangle ABC$ , the Fermat point is the point  $X$  which minimizes the sum of distances from  $A$ ,  $B$ , and  $C$ ,

$$|AX| + |BX| + |CX|. \quad (1)$$

This problem is called FERMAT'S PROBLEM or STEINER'S PROBLEM (Courant and Robbins 1941) and was proposed by Fermat to Torricelli. Torricelli's solution was published by his pupil Viviani in 1659 (Johnson 1929).

If all ANGLES of the TRIANGLE are less than  $120^\circ$  ( $2\pi/3$ ), then the Fermat point is the interior point  $X$  from which each side subtends an ANGLE of  $120^\circ$ , i.e.,

$$\angle BXC = \angle CXA = \angle AXB = 120^\circ. \quad (2)$$

The Fermat point can also be constructed by drawing EQUILATERAL TRIANGLES on the outside of the given TRIANGLE and connecting opposite VERTICES. The

three diagonals in the figure then intersect in the Fermat point. The TRIANGLE CENTER FUNCTION of the Fermat point is

$$\alpha = \csc(A + \tfrac{1}{3}\pi) \quad (3)$$

$$= bc[c^2a^2 + (c^2 + a^2 - b^2)^2][a^2b^2 - (a^2 + b^2 - c^2)^2] \\ \times [4\Delta - \sqrt{3}(b^2 + c^2 - a^2)]. \quad (4)$$

The ANTIPEDAL TRIANGLE is EQUILATERAL and has AREA

$$\Delta' = 2\Delta \left[ 1 + \cot \omega \cot \left( \frac{\pi}{3} \right) \right], \quad (5)$$

where  $\omega$  is the BROCARD ANGLE.

Given three POSITIVE REAL NUMBERS  $l, m, n$ , the "generalized" Fermat point is the point  $P$  of a given ACUTE TRIANGLE  $\triangle ABC$  such that

$$l \cdot PA + m \cdot PB + n \cdot PC \quad (6)$$

is a minimum (Greenberg and Robertello 1965, van de Lindt 1966, Tong and Chua 1995)

#### Fermat's Polygonal Number Theorem

In 1638, Fermat proposed that every POSITIVE INTEGER is a sum of *at most* three TRIANGULAR NUMBERS, four SQUARE NUMBERS, five PENTAGONAL NUMBERS, and  $n$   $n$ -POLYGONAL NUMBERS. Fermat claimed to have a proof of this result, although Fermat's proof has never been found. Gauss proved the triangular case, and noted the event in his diary on July 10, 1796, with the notation

$$**EYRHKA \quad num = \Delta + \Delta + \Delta.$$

This case is equivalent to the statement that every number of the form  $8m + 3$  is a sum of three ODD SQUARES (Duke 1997). More specifically, a number is a sum of three SQUARES IFF it is not of the form  $4^b(8m + 7)$  for  $b \geq 0$ , as first proved by Legendre in 1798.

Euler was unable to prove the square case of Fermat's theorem, but he left partial results which were subsequently used by Lagrange. The square case was finally proved by Jacobi and independently by Lagrange in 1772. It is therefore sometimes known as LAGRANGE'S FOUR-SQUARE THEOREM. In 1813, Cauchy proved the proposition in its entirety.

#### Fermat Polynomial

The POLYNOMIALS obtained by setting  $p(x) = 3x$  and  $q(x) = -2$  in the LUCAS POLYNOMIAL SEQUENCES. The first few Fermat polynomials are

$$\begin{aligned} \mathcal{F}_1(x) &= 1 \\ \mathcal{F}_2(x) &= 3x \\ \mathcal{F}_3(x) &= 9x^2 - 2 \\ \mathcal{F}_4(x) &= 27x^3 - 12x \\ \mathcal{F}_5(x) &= 81x^4 - 54x^2 + 4, \end{aligned}$$

and the first few Fermat-Lucas polynomials are

$$\begin{aligned} f_1(x) &= 3x \\ f_2(x) &= 9x^2 - 4 \\ f_3(x) &= 27x^3 - 18x \\ f_4(x) &= 81x^4 - 72x^2 + 8 \\ f_5(x) &= 243x^5 - 270x^3 + 60x. \end{aligned}$$

Fermat and Fermat-Lucas POLYNOMIALS satisfy

$$\mathcal{F}_n(1) = \mathcal{F}_n$$

$$f_n(1) = f_n$$

where  $\mathcal{F}_n$  are FERMAT NUMBERS and  $f_n$  are FERMAT-LUCAS NUMBERS.

**Fermat's Primality Test**

see FERMAT'S LITTLE THEOREM

**Fermat Prime**

A FERMAT NUMBER  $F_n = 2^{2^n} + 1$  which is PRIME.

see also CONSTRUCTIBLE POLYGON, FERMAT NUMBER

**Fermat's Problem**

In a given ACUTE TRIANGLE  $\triangle ABC$ , locate a point whose distances from  $A$ ,  $B$ , and  $C$  have the smallest possible sum. The solution is the point from which each side subtends an angle of  $120^\circ$ , known as the FERMAT POINT.

see also ACUTE TRIANGLE, FERMAT POINT

**Fermat Pseudoprime**

A Fermat pseudoprime to a base  $a$ , written  $\text{psp}(a)$ , is a COMPOSITE NUMBER  $n$  such that  $a^{n-1} \equiv 1 \pmod{n}$  (i.e., it satisfies FERMAT'S LITTLE THEOREM, sometimes with the requirement that  $n$  must be ODD; Pomerance *et al.* 1980).  $\text{psp}(2)$ s are called POULET NUMBERS or, less commonly, SARRUS NUMBERS or FERMATIANS (Shanks 1993). The first few EVEN  $\text{psp}(2)$ s (including the PRIME 2 as a pseudoprime) are 2, 161038, 215326, ... (Sloane's A006935).

If base 3 is used in addition to base 2 to weed out potential COMPOSITE NUMBERS, only 4709 COMPOSITE NUMBERS remain  $< 25 \times 10^9$ . Adding base 5 leaves 2552, and base 7 leaves only 1770 COMPOSITE NUMBERS.

see also FERMAT'S LITTLE THEOREM, POULET NUMBER, PSEUDOPRIME

**Fermat Quotient**

The Fermat quotient for a number  $a$  and a PRIME base  $p$  is defined as

$$q_p(a) \equiv \frac{a^{p-1} - 1}{p}. \quad (1)$$

If  $p \nmid ab$ , then

$$q_p(ab) = q_p(a) + q_p(b) \quad (2)$$

$$q_p(p \pm 1) = \mp 1 \quad (3)$$

$$q_p(2) = \frac{1}{p} \left( 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots - \frac{1}{p-1} \right), \quad (4)$$

all  $\pmod{p}$ . The quantity  $q_p(2) = (2^{p-1} - 1)/p$  is known to be SQUARE for only two PRIMES: the so-called

WIEFERICH PRIMES 1093 and 3511 (Lehmer 1981, Crandall 1986).

**Fermat's Simple Theorem**

see FERMAT'S LITTLE THEOREM

**Fermat's Spiral**

An ARCHIMEDEAN SPIRAL with  $m = 2$  having polar equation

$$r = a\theta^{1/2},$$

discussed by Fermat in 1636 (MacTutor Archive). It is also known as the PARABOLIC SPIRAL. For any given POSITIVE value of  $\theta$ , there are two corresponding values of  $r$  of opposite signs. The resulting spiral is therefore symmetrical about the line  $y = -x$ . The CURVATURE is

$$\kappa(\theta) = \frac{\frac{3a^2}{4\theta} + a^2\theta}{\left(\frac{a^2}{4\theta} + a^2\theta\right)^{3/2}}.$$

### Fermat Sum Theorem

The only whole number solution to the DIOPHANTINE EQUATION

$$y^3 = x^2 + 2$$

is  $y = 3$ ,  $x = \pm 5$ . This theorem was offered as a problem by Fermat, who suppressed his own proof.

### Fermat's Theorem

A PRIME  $p$  can be represented in an essentially unique manner in the form  $x^2 + y^2$  for integral  $x$  and  $y$  IFF  $p \equiv 1 \pmod{4}$  or  $p = 2$ . It can be restated by letting

$$Q(x, y) \equiv x^2 + y^2,$$

then all RELATIVELY PRIME solutions  $(x, y)$  to the problem of representing  $Q(x, y) = m$  for  $m$  any INTEGER are achieved by means of successive applications of the GENUS THEOREM and COMPOSITION THEOREM. There is an analog of this theorem for EISENSTEIN INTEGERS. *see also* EISENSTEIN INTEGER, SQUARE NUMBER

## FFT

see FAST FOURIER TRANSFORM

## Fiber

A quantity  $F$  corresponding to a FIBER BUNDLE, where the FIBER BUNDLE is a MAP  $f : E \rightarrow B$ , with  $E$  the TOTAL SPACE of the FIBER BUNDLE and  $B$  the BASE SPACE of the FIBER BUNDLE.

see also FIBER BUNDLE, WHITNEY SUM

## Fiber Bundle

A fiber bundle (also called simply a BUNDLE) with FIBER  $F$  is a MAP  $f : E \rightarrow B$  where  $E$  is called the TOTAL SPACE of the fiber bundle and  $B$  the BASE SPACE of the fiber bundle. The main condition for the MAP to be a fiber bundle is that every point in the BASE SPACE  $b \in B$  has a NEIGHBORHOOD  $U$  such that  $f^{-1}(U)$  is HOMEOMORPHIC to  $U \times F$  in a special way. Namely, if

$$h : f^{-1}(U) \rightarrow U \times F$$

is the HOMEOMORPHISM, then

$$\text{proj}_U \circ h = f|_{f^{-1}(U)},$$

where the MAP  $\text{proj}_U$  means projection onto the  $U$  component. The homeomorphisms  $h$  which "commute with projection" are called local TRIVIALIZATIONS for the fiber bundle  $f$ . In other words,  $E$  looks like the product  $B \times F$  (at least locally), except that the fibers  $f^{-1}(x)$  for  $x \in B$  may be a bit "twisted."

Examples of fiber bundles include any product  $B \times F \rightarrow B$  (which is a bundle over  $B$  with FIBER  $F$ ), the MÖBIUS STRIP (which is a fiber bundle over the CIRCLE with FIBER given by the unit interval  $[0,1]$ ; i.e., the BASE SPACE is the CIRCLE), and  $S^3$  (which is a bundle over  $S^2$  with fiber  $S^1$ ). A special class of fiber bundle is the VECTOR BUNDLE, in which the FIBER is a VECTOR SPACE.

see also BUNDLE, FIBER SPACE, FIBRATION

## Fiber Space

A fiber space, depending on context, means either a FIBER BUNDLE or a FIBRATION.

see also FIBER BUNDLE, FIBRATION

**Fibonacci Dual Theorem**

Let  $F_n$  be the  $n$ th FIBONACCI NUMBER. Then the sequence  $\{F_n\}_{n=2}^{\infty} = \{1, 2, 3, 5, 8, \dots\}$  is COMPLETE, even if one is restricted to subsequences in which no two consecutive terms are both passed over (until the desired total is reached; Brown 1965, Honsberger 1985).

see also COMPLETE SEQUENCE, FIBONACCI NUMBER.

**Fibonacci Hyperbolic Cosine**

Let

$$\psi \equiv 1 + \phi = \frac{1}{2}(3 + \sqrt{5}) \approx 2.618034 \quad (1)$$

where  $\phi$  is the GOLDEN RATIO, and

$$\alpha = \ln \phi \approx 0.4812118. \quad (2)$$

Then define

$$\text{cFh}(x) \equiv \frac{\psi^{x+1/2} + \psi^{-(x+1/2)}}{\sqrt{5}} \quad (3)$$

$$= \frac{\phi^{(2x+1)} + \phi^{-(2x+1)}}{\sqrt{5}} \quad (4)$$

$$= \frac{2}{\sqrt{5}} \cosh[(2x+1)\alpha]. \quad (5)$$

This function satisfies

$$\text{cFh}(-x) = \text{cFh}(x-1). \quad (6)$$

For  $n \in \mathbb{Z}$ ,  $\text{cFh}(n) = F_{2n+1}$  where  $F_n$  is a FIBONACCI NUMBER.

**Fibonacci Hyperbolic Tangent**

$$\text{tFh}(x) \equiv \frac{\text{sFh}(x)}{\text{cFh}(x)},$$

where  $\text{sFh}(x)$  is the FIBONACCI HYPERBOLIC SINE and  $\text{cFh}(x)$  is the FIBONACCI HYPERBOLIC COSINE.

References

Trzaska, Z. W. "On Fibonacci Hyperbolic Trigonometry and Modified Numerical Triangles." *Fib. Quart.* **34**, 129-138, 1996.

**Fibonacci Identity**

Since

$$|(a+ib)(c+id)| = |a+ib||c+di| \quad (1)$$

$$|(ac-bd) + i(bc+ad)| = \sqrt{a^2+b^2}\sqrt{c^2+d^2}, \quad (2)$$

it follows that

$$(a^2+b^2)(c^2+d^2) = (ac-bd)^2 + (bc+ad)^2 \equiv e^2 + f^2. \quad (3)$$

This identity implies the 2-D CAUCHY-SCHWARZ SUM INEQUALITY.

see also CAUCHY-SCHWARZ SUM INEQUALITY, EULER FOUR-SQUARE IDENTITY

References

Petkovšek, M.; Wilf, H. S.; and Zeilberger, D. *A=B*. Wellesley, MA: A. K. Peters, p. 9, 1996.

**Fibonacci Matrix**

A SQUARE MATRIX related to the FIBONACCI NUMBERS. The simplest is the FIBONACCI  $Q$ -MATRIX.

**Fibonacci  $n$ -Step Number**

An  $n$ -step Fibonacci sequence is given by defining  $F_k = 0$  for  $k \leq 0$ ,  $F_1 = F_2 = 1$ ,  $F_3 = 2$ , and

$$F_k = \sum_{i=1}^n F_{k-i} \quad (1)$$

for  $k > 3$ . The case  $n = 1$  corresponds to the degenerate 1, 1, 2, 2, 2, 2, ...,  $n = 2$  to the usual FIBONACCI NUMBERS 1, 1, 2, 3, 5, 8, ... (Sloane's A000045),  $n = 3$  to the TRIBONACCI NUMBERS 1, 1, 2, 4, 7, 13, 24, 44, 81, ... (Sloane's A000073),  $n = 4$  to the TETRANACCI NUMBERS 1, 1, 2, 4, 8, 15, 29, 56, 108, ... (Sloane's A000078), etc.

The limit  $\lim_{k \rightarrow \infty} F_k/F_{k-1}$  is given by solving

$$x^n(2-x) = 1 \quad (2)$$

for  $x$  and taking the REAL ROOT  $x > 1$ . If  $n = 2$ , the equation reduces to

$$x^2(2-x) = 1 \quad (3)$$

$$x^3 - 2x^2 + 1 = (x-1)(x^2 - x - 1) = 0, \quad (4)$$

giving solutions

$$x = 1, \frac{1}{2}(1 \pm \sqrt{5}). \quad (5)$$

The ratio is therefore

$$x = \frac{1}{2}(1 + \sqrt{5}) = \phi = 1.618\dots, \quad (6)$$

which is the GOLDEN RATIO, as expected. Solutions for  $n = 1, 2, \dots$  are given numerically by 1, 1.61803, 1.83929, 1.92756, 1.96595, ..., approaching 2 as  $n \rightarrow \infty$ . see also FIBONACCI NUMBER, TRIBONACCI NUMBER

**References**

Sloane, N. J. A. Sequences A000045/M0692, A000073/M1074, and A000078/M1108 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Fibonacci Number**

The sequence of numbers defined by the  $U_n$  in the LUCAS SEQUENCE. They are companions to the LUCAS NUMBERS and satisfy the same RECURRENCE RELATION,

$$F_n = F_{n-2} + F_{n-1} \quad (1)$$

for  $n = 3, 4, \dots$ , with  $F_1 = F_2 = 1$ . The first few Fibonacci numbers are 1, 1, 2, 3, 5, 8, 13, 21, ... (Sloane's A000045). The Fibonacci numbers give the number of pairs of rabbits  $n$  months after a single pair begins breeding (and newly born bunnies are assumed to begin breeding when they are two months old).

The ratios of alternate Fibonacci numbers are given by the convergents to  $\phi^{-2}$ , where  $\phi$  is the GOLDEN RATIO,

and are said to measure the fraction of a turn between successive leaves on the stalk of a plant (PHYLLOTAXIS): 1/2 for elm and linden, 1/3 for beech and hazel, 2/5 for oak and apple, 3/8 for poplar and rose, 5/13 for willow and almond, etc. (Coxeter 1969, Ball and Coxeter 1987). The Fibonacci numbers are sometimes called PINE CONE NUMBERS (Pappas 1989, p. 224)

Another RECURRENCE RELATION for the Fibonacci numbers is

$$F_{n+1} = \left\lfloor \frac{F_n(1 + \sqrt{5}) + 1}{2} \right\rfloor = \left\lfloor \phi F_n + \frac{1}{2} \right\rfloor, \quad (2)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $\phi$  is the GOLDEN RATIO. This expression follows from the more general RECURRENCE RELATION that

$$\begin{vmatrix} F_n & F_{n+1} & \cdots & F_{n+k} \\ F_{n+k+1} & F_{n+k+2} & \cdots & F_{n+2k} \\ \vdots & \vdots & \ddots & \vdots \\ F_{n+k(k-1)+1} & F_{n+k(k-1)+2} & \cdots & F_{n+k^2} \end{vmatrix} = 0. \quad (3)$$

The GENERATING FUNCTION for the Fibonacci numbers is

$$g(x) = \sum_{n=0}^{\infty} F_n x^n = \frac{1}{1-x-x^2}. \quad (4)$$

Yuri Matijasevič (1970) proved that the equation  $n = F_{2m}$  is a DIOPHANTINE EQUATION. This led to the proof of the impossibility of the tenth of HILBERT'S PROBLEMS (does there exist a general method for solving DIOPHANTINE EQUATIONS?) by Julia Robinson and Martin Davis in 1970.

The Fibonacci number  $F_{n+1}$  gives the number of ways for  $2 \times 1$  DOMINOES to cover a  $2 \times n$  CHECKERBOARD, as illustrated in the following diagrams (Dickau).

The number of ways of picking a SET (including the EMPTY SET) from the numbers 1, 2, ...,  $n$  without picking two consecutive numbers is  $F_{n+2}$ . The number of ways of picking a set (including the EMPTY SET) from the numbers 1, 2, ...,  $n$  without picking two consecutive numbers (where 1 and  $n$  are now consecutive) is  $L_n = F_{n+1} + F_{n-1}$ , where  $L_n$  is a LUCAS NUMBER. The probability of not getting two heads in a row in  $n$  tosses of a COIN is  $F_{n+2}/2^n$  (Honsberger 1985, pp. 120–122). Fibonacci numbers are also related to the number of ways in which  $n$  COIN TOSSES can be made such that there are not three consecutive heads or tails. The number of ideals of an  $n$ -element FENCE POSET is the Fibonacci number  $F_n$ .

Sum identities are

$$\sum_{k=1}^n F_k = F_{n+2} - 1. \quad (5)$$

$$F_1 + F_3 + F_5 + \dots + F_{2k+1} = F_{2k+2} \quad (6)$$

$$1 + F_2 + F_4 + F_6 + \dots + F_{2k} = F_{2k+1} \quad (7)$$

$$\sum_{k=1}^n F_k^2 = F_n F_{n+1} \quad (8)$$

$$F_{2n} = F_{n+1}^2 - F_{n-1}^2 \quad (9)$$

$$F_{3n} = F_{n+1}^3 + F_n^3 + F_{n-1}^3. \quad (10)$$

Additional RECURRENCE RELATIONS are CASSINI'S IDENTITY

$$F_{n-1}F_{n+1} - F_n^2 = (-1)^n \quad (11)$$

and the relations

$$F_{2n+1} = 1 + F_2 + F_4 + \dots + F_{2n} \quad (12)$$

$$F_{n+1}^2 = 4F_n F_{n-1} + F_{n-2}^2 \quad (13)$$

(Brousseau 1972),

$$F_{n+m} = F_{n-1}F_m + F_n F_{m+1} \quad (14)$$

$$F_{(k+1)n} = F_{n-1}F_{kn} + F_n F_{k+1n} \quad (15)$$

(Honsberger 1985, p. 107),

$$F_n = F_l F_{n-l+1} + F_{l-1} F_{n-l}, \quad (16)$$

so if  $l = n - l + 1$ , then  $2l = n + 1$  and  $l = (n + 1)/2$

$$F_n = F_{(n+1)/2}^2 + F_{(n-1)/2}^2. \quad (17)$$

Letting  $k \equiv (n - 1)/2$ ,

$$F_{2k+1} = F_{k+1}^2 + F_k^2 \quad (18)$$

$$F_{n+2}^2 - F_{n+1}^2 = F_n F_{n+3} \quad (19)$$

$$F_n^2 = F_{n-1}^2 + 3F_{n-2}^2 + 2F_{n-2}F_{n-3}. \quad (20)$$

Sum FORMULAS for  $F_n$  include

$$F_n = \frac{1}{2^{n-1}} \left[ \binom{n}{1} + 5 \binom{n}{3} + 5^2 \binom{n}{5} + \dots \right] \quad (21)$$

$$F_{n+1} = \binom{n}{0} + \binom{n-1}{1} + \binom{n-2}{2} + \dots \quad (22)$$

Cesàro derived the FORMULAS

$$\sum_{k=0}^n \binom{n}{k} F_k = F_{2n} \quad (23)$$

$$\sum_{k=0}^n \binom{n}{k} 2^k F_k = F_{3n} \quad (24)$$

(Honsberger 1985, pp. 109–110). Additional identities can be found throughout the *Fibonacci Quarterly* journal. A list of 47 generalized identities are given by Halton (1965).

In terms of the LUCAS NUMBER  $L_n$ ,

$$F_{2n} = F_n L_n \quad (25)$$

$$F_{2n}(L_{2n}^2 - 1) = F_{6n} \quad (26)$$

$$F_{m+p} + (-1)^{p+1} F_{m-p} = F_p L_m \quad (27)$$

$$\sum_{k=a+1}^{a+4n} F_k = F_{a+4n+2} - F_{a+2} = F_{2n} L_{a+2n+2} \quad (28)$$

(Honsberger 1985, pp. 111–113). A remarkable identity is

$$\exp(L_1 x + \frac{1}{2} L_2 x^2 + \frac{1}{3} L_3 x^3 + \dots) = F_1 + F_2 x + F_3 x^2 + \dots \quad (29)$$

(Honsberger 1985, pp. 118–119). It is also true that

$$5F_n^2 = L_n^2 - 4(-1)^n \quad (30)$$

and

$$\frac{L_n^2 - (-1)^a L_{n+a}^2}{F_n^2 - (-1)^a F_{n+a}^2} = 5 \quad (31)$$

for  $a$  ODD, and

$$\frac{L_n^2 + L_{n+a}^2 - 8(-1)^n}{F_n^2 + F_{n+a}^2} = 5 \quad (32)$$

for  $a$  EVEN (Freitag 1996).

The equation (1) is a LINEAR RECURRENCE SEQUENCE

$$x_n = Ax_{n-1} + Bx_{n-2} \quad n \geq 3, \quad (33)$$

so the closed form for  $F_n$  is given by

$$F_n = \frac{\alpha^n - \beta^n}{\alpha - \beta}, \quad (34)$$

so

$$\frac{F_{n+r}}{F_n} = \alpha^r. \quad (50)$$

$$S' = \sum_{n=1}^{\infty} \frac{F_n}{F_{n+1}F_{n+2}} = 1 \quad (51)$$

(Honsberger 1985, pp. 138 and 242–243). The MILLIN SERIES has sum

$$S'' = \sum_{n=0}^{\infty} \frac{1}{F_{2n}} = \frac{1}{2}(7 - \sqrt{5}) \quad (52)$$

(Honsberger 1985, pp. 135–137).

The Fibonacci numbers are COMPLETE. In fact, dropping one number still leaves a COMPLETE SEQUENCE, although dropping two numbers does not (Honsberger 1985, pp. 123 and 126). Dropping two terms from the Fibonacci numbers produces a sequence which is not even WEAKLY COMPLETE (Honsberger 1985, p. 128). However, the sequence

$$F'_n \equiv F_n - (-1)^n \quad (53)$$

is WEAKLY COMPLETE, even with any finite subsequence deleted (Graham 1964).  $\{F_n^2\}$  is not COMPLETE, but  $\{F_n^2\} + \{F_n^2\}$  are.  $2^{N-1}$  copies of  $\{F_n^N\}$  are COMPLETE.

For a discussion of SQUARE Fibonacci numbers, see Cohn (1964), who proved that the only SQUARE NUMBER Fibonacci numbers are 1 and  $F_{12} = 144$  (Cohn 1964, Guy 1994). Ming (1989) proved that the only TRIANGULAR Fibonacci numbers are 1, 3, 21, and 55. The Fibonacci and LUCAS NUMBERS have no common terms except 1 and 3. The only CUBIC Fibonacci numbers are 1 and 8.

$$(F_n F_{n+3}, 2F_{n+1} F_{n+2}, F_{2n+3} = F_{n+1}^2 + F_{n+2}^2) \quad (54)$$

is a PYTHAGOREAN TRIPLE.

$$F_{4n}^2 + 8F_{2n}(F_{2n} + F_{6n}) = (3F_{4n})^2 \quad (55)$$

is always a SQUARE NUMBER (Honsberger 1985, p. 243).

In 1975, James P. Jones showed that the Fibonacci numbers are the POSITIVE INTEGER values of the POLYNOMIAL

$$P(x, y) = -y^5 + 2y^4x + y^3x^2 - 2y^2x^3 - y(x^4 - 2) \quad (56)$$

for GAUSSIAN INTEGERS  $x$  and  $y$  (Le Lionnais 1983). If  $n$  and  $k$  are two POSITIVE INTEGERS, then between  $n^k$  and  $n^{k+1}$ , there can never occur more than  $n$  Fibonacci numbers (Honsberger 1985, pp. 104–105).

Every  $F_n$  that is PRIME has a PRIME  $n$ , but the converse is not necessarily true. The first few PRIME Fibonacci numbers are for  $n = 3, 4, 5, 7, 11, 13, 17, 23, 29, 43,$

47, 83, 131, 137, 359, 431, 433, 449, 509, 569, 571, ... (Sloane's A001605; Dubner and Keller 1998). Gardner's statement that  $F_{531}$  is prime is incorrect, especially since 531 is not even PRIME (Gardner 1979, p. 161). It is not known if there are an INFINITE number of Fibonacci primes.

The Fibonacci numbers  $F_n$ , are SQUAREFUL for  $n = 6, 12, 18, 24, 25, 30, 36, 42, 48, 50, 54, 56, 60, 66, \dots, 300, 306, 312, 324, 325, 330, 336, \dots$  (Sloane's A037917) and SQUAREFREE for  $n = 1, 2, 3, 4, 5, 7, 8, 9, 10, 11, 13, \dots$  (Sloane's A037918). The largest known SQUAREFUL Fibonacci number is  $F_{336}$ , and no SQUAREFUL Fibonacci numbers  $F_p$  are known with  $p$  PRIME.

## Fibonacci Polynomial

The  $W$  POLYNOMIALS obtained by setting  $p(x) = x$  and  $q(x) = 1$  in the LUCAS POLYNOMIAL SEQUENCE. (The

corresponding  $w$  POLYNOMIALS are called LUCAS POLYNOMIALS.) The Fibonacci polynomials are defined by the RECURRENCE RELATION

$$F_{n+1}(x) = xF_n(x) + F_{n-1}(x), \quad (1)$$

with  $F_1(x) = 1$  and  $F_2(x) = x$ . They are also given by the explicit sum formula

$$F_n(x) = \sum_{j=0}^{\lfloor (n-1)/2 \rfloor} \binom{n-j-1}{j} x^{n-2j-1}, \quad (2)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT. The first few Fibonacci polynomials are

$$\begin{aligned} F_1(x) &= 1 \\ F_2(x) &= x \\ F_3(x) &= x^2 + 1 \\ F_4(x) &= x^3 + 2x \\ F_5(x) &= x^4 + 3x^2 + 1. \end{aligned}$$

The Fibonacci polynomials are normalized so that

$$F_n(1) = F_n, \quad (3)$$

where the  $F_n$ s are FIBONACCI NUMBERS.

The Fibonacci polynomials are related to the MORGAN-VOYCE POLYNOMIALS by

$$F_{2n+1}(x) = b_n(x^2) \quad (4)$$

$$F_{2n+2}(x) = xB_n(x^2) \quad (5)$$

(Swamy 1968).

## Fibonacci Pseudoprime

Consider a LUCAS SEQUENCE with  $P > 0$  and  $Q = \pm 1$ . A Fibonacci pseudoprime is a COMPOSITE NUMBER  $n$  such that

$$V_n \equiv P \pmod{n}.$$

There exist no EVEN Fibonacci pseudoprimes with parameters  $P = 1$  and  $Q = -1$  (Di Porto 1993) or  $P = Q = 1$  (André-Jeannin 1996). André-Jeannin (1996) also proved that if  $(P, Q) \neq (1, -1)$  and  $(P, Q) \neq (1, 1)$ , then there exists at least one EVEN Fibonacci pseudoprime with parameters  $P$  and  $Q$ .

see also PSEUDOPRIME

**Fibonacci Q-Matrix**

A FIBONACCI MATRIX of the form

$$M = \begin{bmatrix} m & 1 \\ 1 & 0 \end{bmatrix}. \quad (1)$$

If  $U$  and  $V$  are defined as BINET FORMS

$$U_n = mU_{n-1} + U_{n-2} \quad (U_0 = 0, U_1 = 1) \quad (2)$$

$$V_n = mV_{n-1} + V_{n-2} \quad (V_0 = 2, V_1 = m), \quad (3)$$

then

$$M = \begin{bmatrix} U_{n+1} & U_n \\ U_n & U_{n-1} \end{bmatrix} \quad (4)$$

$$M^{-1} = M - mI = \begin{bmatrix} 0 & 1 \\ 1 & -m \end{bmatrix}. \quad (5)$$

Defining

$$Q \equiv \begin{bmatrix} F_2 & F_1 \\ F_1 & F_0 \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix}, \quad (6)$$

then

$$Q^n = \begin{bmatrix} F_{n+1} & F_n \\ F_n & F_{n-1} \end{bmatrix} \quad (7)$$

(Honsberger 1985, pp. 106–107).

**Fibonacci Sequence**

see FIBONACCI NUMBER

**Fibration**

If  $f : E \rightarrow B$  is a FIBER BUNDLE with  $B$  a PARACOMPACT TOPOLOGICAL SPACE, then  $f$  satisfies the HOMOTOPY LIFTING PROPERTY with respect to all TOPOLOGICAL SPACES. In other words, if  $g : [0, 1] \times X \rightarrow B$  is a HOMOTOPY from  $g_0$  to  $g_1$ , and if  $g'_0$  is a LIFT of the MAP  $g_0$  with respect to  $f$ , then  $g$  has a LIFT to a MAP  $g'$  with respect to  $f$ . Therefore, if you have a HOMOTOPY of a MAP into  $B$ , and if the beginning of it has a LIFT, then that LIFT can be extended to a LIFT of the HOMOTOPY itself.

A fibration is a MAP between TOPOLOGICAL SPACES  $f : E \rightarrow B$  such that it satisfies the HOMOTOPY LIFTING PROPERTY.

see also FIBER BUNDLE, FIBER SPACE

**Field**

A field is any set of elements which satisfy the FIELD AXIOMS for both addition and multiplication and is a commutative DIVISION ALGEBRA. An archaic word for a field is RATIONAL DOMAIN. A field with a finite number of members is known as a FINITE FIELD or GALOIS FIELD.

Because the identity condition must be different for addition and multiplication, every field must have at least two elements. Examples include the COMPLEX NUMBERS ( $\mathbb{C}$ ), RATIONAL NUMBERS ( $\mathbb{Q}$ ), and REAL NUMBERS ( $\mathbb{R}$ ), but *not* the INTEGERS ( $\mathbb{Z}$ ), which form a RING. It has been proven by Hilbert and Weierstraß that all generalizations of the field concept to triplets of elements are equivalent to the field of COMPLEX NUMBERS.

see also ADJUNCTION, ALGEBRAIC NUMBER FIELD, COEFFICIENT FIELD, CYCLOTOMIC FIELD, FIELD AXIOMS, FIELD EXTENSION, FUNCTION FIELD, GALOIS FIELD, MAC LANE'S THEOREM, MODULE, NUMBER FIELD, QUADRATIC FIELD, RING, SKEW FIELD, VECTOR FIELD

**Field Axioms**

The field axioms are generally written in additive and multiplicative pairs.

Name	Addition	Multiplication
Commutativity	$a + b = b + a$	$ab = ba$
Associativity	$(a + b) + c = a + (b + c)$	$(ab)c = a(bc)$
Distributivity	$a(b + c) = ab + ac$	$(a + b)c = ac + bc$
Identity	$a + 0 = a = 0 + a$	$a \cdot 1 = a = 1 \cdot a$
Inverses	$a + (-a) = 0 = (-a) + a$	$aa^{-1} = 1 = a^{-1}a$ if $a \neq 0$

see also ALGEBRA, FIELD

**Field Extension**

A FIELD  $L$  is said to be a field extension of field  $K$  if  $K$  is a SUBFIELD of  $L$ . This is denoted  $L/K$  (note that this NOTATION conflicts with that of a QUOTIENT GROUP). The COMPLEX NUMBERS are a field extension of the REAL NUMBERS, and the REAL NUMBERS are a field extension of the RATIONAL NUMBERS.

see also FIELD

**Fields Medal**

The mathematical equivalent of the Nobel Prize (there is no Nobel Prize in mathematics) which is awarded by the International Mathematical Union every four years to one or more outstanding researchers, usually under 40 years of age. The first Fields Medal was awarded in 1936.

## Fifteen Theorem

A theorem due to Conway *et al.* (1997) which states that, if a POSITIVE definite QUADRATIC FORM with integral matrix entries represents all natural numbers up to 15, then it represents all natural numbers. This theorem contains LAGRANGE'S FOUR-SQUARE THEOREM, since every number up to 15 is the sum of at most four SQUARES.

see also INTEGER-MATRIX FORM, LAGRANGE'S FOUR-SQUARE THEOREM, QUADRATIC FORM

## Figurate Number

A number which can be represented by a regular geometrical arrangement of equally spaced points. If the arrangement forms a REGULAR POLYGON, the number is called a POLYGONAL NUMBER. The polygonal numbers illustrated above are called triangular, square, pentagonal, and hexagon numbers, respectively. Figurate numbers can also form other shapes such as centered polygons, L-shapes, 3-dimensional solids, etc. The following table lists the most common types of figurate numbers.

Name	Formula
biquadratic	$n^4$
centered cube	$(2n - 1)(n^2 - n + 1)$
centered pentagonal	$\frac{1}{2}(5n^2 - 5n + 2)$
centered square	$n^2 + (n - 1)^2$
centered triangular	$\frac{1}{2}(3n^2 - 3n + 2)$
cubic	$n^3$
decagonal	$4n^2 - 3n$
gnomic	$2n - 1$
heptagonal	$\frac{1}{2}n(5n - 3)$
heptagonal pyramidal	$\frac{1}{6}n(n + 1)(5n - 2)$
hex	$3n^2 - 3n + 1$
hexagonal	$n(2n - 1)$
hexagonal pyramidal	$\frac{1}{6}n(n + 1)(4n - 1)$
octagonal	$n(3n - 2)$
octahedral	$\frac{1}{3}n(2n^2 + 1)$
pentagonal	$\frac{1}{2}n(3n - 1)$
pentagonal pyramidal	$\frac{1}{2}n^2(n + 1)$
pentatope	$\frac{1}{24}n(n + 1)(n + 2)(n + 3)$
pronic number	$n(n + 1)$
rhombic dodecahedral	$(2n - 1)(2n^2 - 2n + 1)$
square	$n^2$
stella octangula	$n(2n^2 - 1)$
tetrahedral	$\frac{1}{6}n(n + 1)(n + 2)$
triangular	$\frac{1}{2}n(n + 1)$
truncated octahedral	$16n^3 - 33n^2 + 24n - 6$
truncated tetrahedral	$\frac{1}{6}n(23n^2 - 27n + 10)$

An  $n$ -D FIGURATE NUMBER can be defined by

$$f_{m,s}^r = \frac{(rs + m - s)(r + m - 2)}{m!(r - 1)!}.$$

### Figurate Number Triangle

A PASCAL'S TRIANGLE written in a square grid and padded with zeroes, as written by Jakob Bernoulli (Smith 1984). The figurate number triangle therefore has entries

$$a_{ij} = \binom{i}{j},$$

where  $i$  is the row number,  $j$  the column number, and  $\binom{i}{j}$  a BINOMIAL COEFFICIENT. Written out explicitly (beginning each row with  $j = 0$ ),

$$\begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 1 & 0 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 2 & 1 & 0 & 0 & 0 & 0 & \cdots \\ 1 & 3 & 3 & 1 & 0 & 0 & 0 & \cdots \\ 1 & 4 & 6 & 4 & 1 & 0 & 0 & \cdots \\ 1 & 5 & 10 & 10 & 5 & 1 & 0 & \cdots \\ 1 & 6 & 15 & 20 & 15 & 6 & 1 & \cdots \\ 1 & 7 & 21 & 35 & 35 & 21 & 7 & \ddots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

Then we have the sum identities

$$\begin{aligned} \sum_{j=0}^i a_{ij} &= 2^i \\ \sum_{j=1}^i a_{ij} &= 2^i - 1 \\ \sum_{i=0}^n a_{ij} &= a_{(n+1),(j+1)} = \frac{n+1}{j+1} a_{nj}. \end{aligned}$$

### Figure Eight Knot

see FIGURE-OF-EIGHT KNOT

### Figure Eight Surface

see EIGHT SURFACE

### Figure-of-Eight Knot

The knot 04<sub>001</sub>, which is the unique PRIME KNOT of four crossings, and which is a 2-EMBEDDABLE KNOT. It is AMPHICHIRAL. It is also known as the HEILICH KNOT and SAVOY KNOT, and it has BRAID WORD  $\sigma_1 \sigma_2^{-1} \sigma_1 \sigma_2^{-1}$ .

#### References

Owen, P. *Knots*. Philadelphia, PA: Courage, p. 16, 1993.

### Figures

A number  $x$  is said to have " $n$  figures" if it takes  $n$  DIGITS to express it. The number of figures is therefore equal to one more than the POWER of 10 in the SCIENTIFIC NOTATION representation of the number. The word is most frequently used in reference to monetary amounts, e.g., a "six-figure salary" would fall in the range of \$100,000 to \$999,999.

see also DIGIT, SCIENTIFIC NOTATION, SIGNIFICANT FIGURES

### Filon's Integration Formula

A formula for NUMERICAL INTEGRATION,

$$\begin{aligned} \int_{x_0}^{x_n} f(x) \cos(tx) dx \\ = h \{ \alpha(th) [f_{2n} \sin(tx_{2n}) - f_0 \sin(tx_0)] \\ + \beta(th) C_{2n} + \gamma(th) C_{2n-1} + \frac{2}{45} th^4 S'_{2n-1} \} - R_n, \end{aligned} \quad (1)$$

where

$$C_{2n} = \sum_{i=0}^n f_{2i} \cos(tx_{2i}) - \frac{1}{2} [f_{2n} \cos(tx_{2n}) + f_0 \cos(tx_0)] \quad (2)$$

$$C_{2n-1} = \sum_{i=1}^n f_{2i-1} \cos(tx_{2i-1}) \quad (3)$$

$$S'_{2n-1} = \sum_{i=1}^n f_{2i-1}^{(3)} \sin(tx_{2i-1}) \quad (4)$$

$$\alpha(\theta) = \frac{1}{\theta} + \frac{\sin(2\theta)}{2\theta^2} - \frac{2\sin^2\theta}{\theta^3} \quad (5)$$

$$\beta(\theta) = 2 \left[ \frac{1 + \cos^2\theta}{\theta^2} - \frac{\sin(2\theta)}{\theta^3} \right] \quad (6)$$

$$\gamma(\theta) = 4 \left( \frac{\sin\theta}{\theta^3} - \frac{\cos\theta}{\theta^2} \right), \quad (7)$$

and the remainder term is

$$R_n = \frac{1}{90} nh^5 f^{(4)}(\xi) + \mathcal{O}(th^7). \quad (8)$$

## Filter

Formally, a filter is defined in terms of a SET  $X$  and a SET  $\Phi$  of SUBSETS of  $X$ . Then  $\Phi$  is called a filter if

1.  $X \in \Phi$ ,
2. the EMPTY SET  $\emptyset \notin \Phi$ ,
3.  $A \subset B \subset X$  and  $A \in \Phi$  IMPLIES  $B \in \Phi$ ,
4. and  $A, B \in \Phi$  IMPLIES  $A \cup B \in \Phi$ .

Informally, a filter is a function or procedure which removes unwanted parts of a signal. The concept of filtering and filter functions is particularly useful in engineering. One particularly elegant method of filtering FOURIER TRANSFORMS a signal into frequency space, performs the filtering operation there, then transforms back into the original space (Press *et al.* 1992).

## Fine's Equation

$$\prod_{n=1}^{\infty} \frac{(1-q^{2n})(1-q^{3n})(1-q^{8n})(1-q^{12n})}{(1-q^n)(1-q^{24n})} = 1 + \sum_{N=1}^{\infty} E_{1,5,7,11}(N; 24)q^N,$$

where  $E$  is the sum of the DIVISORS of  $N$  CONGRUENT to 1, 5, 7, and 11 (mod 24) minus the sum of DIVISORS of  $N$  CONGRUENT to -1, -5, -7, and -11 (mod 24).

see also  $q$ -SERIES

## Finite

A SET which contains a NONNEGATIVE integral number of elements is said to be finite. A SET which is not finite is said to be INFINITE. A finite or COUNTABLY INFINITE SET is said to be COUNTABLE. While the meaning of the term "finite" is fairly clear in common usage, precise definitions of FINITE and INFINITE are needed in technical mathematics and especially in SET THEORY.

see also COUNTABLE SET, COUNTABLY INFINITE SET, INFINITE, SET THEORY, UNCOUNTABLY INFINITE SET

## Finite Difference

The finite difference is the discrete analog of the DERIVATIVE. The finite FORWARD DIFFERENCE of a function  $f_p$  is defined as

$$\Delta f_p \equiv f_{p+1} - f_p, \quad (1)$$

and the finite BACKWARD DIFFERENCE as

$$\nabla f_p \equiv f_p - f_{p-1}. \quad (2)$$

If the values are tabulated at spacings  $h$ , then the notation

$$f_p \equiv f(x_0 + ph) \equiv f(x) \quad (3)$$

is used. The  $k$ th FORWARD DIFFERENCE would then be written as  $\Delta^k f_p$ , and similarly, the  $k$ th BACKWARD DIFFERENCE as  $\nabla^k f_p$ .

However, when  $f_p$  is viewed as a discretization of the continuous function  $f(x)$ , then the finite difference is sometimes written

$$\Delta f(x) \equiv f(x + \frac{1}{2}) - f(x - \frac{1}{2}) = 2 I_1(x) * f(x), \quad (4)$$

where  $*$  denotes CONVOLUTION and  $I_1(x)$  is the odd IMPULSE PAIR. The finite difference operator can therefore be written

$$\tilde{\Delta} = 2 I_1 *. \quad (5)$$

An  $n$ th POWER has a constant  $n$ th finite difference. For example, take  $n = 3$  and make a DIFFERENCE TABLE,

$$\begin{array}{ccccccc} x & x^3 & & & & & \\ 1 & 1 & \Delta & \Delta^2 & & & \\ 2 & 8 & 7 & 12 & \Delta^3 & \Delta^4 & \\ 3 & 27 & 19 & 18 & 6 & 0 & \\ 4 & 64 & 37 & 24 & 6 & & \\ 5 & 125 & 61 & 24 & & & \end{array} \quad (6)$$

The  $\Delta^3$  column is the constant 6.

Finite difference formulas can be very useful for extrapolating a finite amount of data in an attempt to find the general term. Specifically, if a function  $f(n)$  is known at only a few discrete values  $n = 0, 1, 2, \dots$  and it is desired to determine the analytical form of  $f$ , the following procedure can be used if  $f$  is assumed to be a POLYNOMIAL function. Denote the  $n$ th value in the SEQUENCE of interest by  $a_n$ . Then define  $b_n$  as the FORWARD DIFFERENCE  $\Delta_n \equiv a_{n+1} - a_n$ ,  $c_n$  as the second FORWARD DIFFERENCE  $\Delta_n^2 \equiv b_{n+1} - b_n$ , etc., constructing a table as follows

$$\begin{array}{ccccccc} a_0 \equiv f(0) & a_1 \equiv f(1) & a_2 \equiv f(2) & \dots & a_p \equiv f(p) \\ b_0 \equiv a_1 - a_0 & b_1 \equiv a_2 - a_1 & \dots & b_{p-1} \equiv a_p - a_{p-1} \\ c_0 \equiv b_1 - b_0 & \dots & \dots & & \\ \vdots & & & & \end{array} \quad (7)$$

Continue computing  $d_0$ ,  $e_0$ , etc., until a 0 value is obtained. Then the POLYNOMIAL function giving the values  $a_n$  is given by

$$f(n) = \sum_{k=0}^p \alpha_k \binom{n}{k} \quad (8)$$

$$= a_0 + b_0 n + \frac{c_0 n(n-1)}{2} + \frac{d_0 n(n-1)(n-2)}{2 \cdot 3} + \dots \quad (9)$$

When the notation  $\Delta_0 \equiv a_0$ ,  $\Delta_0^2 \equiv b_0$ , etc., is used, this beautiful equation is called NEWTON'S FORWARD DIFFERENCE FORMULA. To see a particular example, consider a SEQUENCE with first few values of 1, 19, 143, 607, 1789, 4211, and 8539. The difference table is then given by

1	19	143	607	1789	4211	8539
18	124	464	1182	2422	4328	
106	340	718	1240	1906		
234	378	522	666			
144	144	144				
0	0					

Reading off the first number in each row gives  $a_0 = 1$ ,  $b_0 = 18$ ,  $c_0 = 106$ ,  $d_0 = 234$ ,  $e_0 = 144$ . Plugging these in gives the equation

$$f(n) = 1 + 18n + 53n(n-1) + 39n(n-1)(n-2) + 6n(n-1)(n-2)(n-3), \quad (10)$$

which simplifies to  $f(n) = 6n^4 + 3n^3 + 2n^2 + 7n + 1$ , and indeed fits the original data exactly!

Beyer (1987) gives formulas for the derivatives

$$h^n \frac{d^n f(x_0 + ph)}{dx^n} \equiv h^n \frac{d^n f_p}{dx^n} \equiv \frac{d^n f_p}{dp^n} \quad (11)$$

(Beyer 1987, pp. 449–451) and integrals

$$\int_{x_0}^{x_n} f(x) dx = h \int_0^n f_p dp \quad (12)$$

(Beyer 1987, pp. 455–456) of finite differences.

Finite differences lead to DIFFERENCE EQUATIONS, finite analogs of DIFFERENTIAL EQUATIONS. In fact, UMBRAL CALCULUS displays many elegant analogs of well-known identities for continuous functions. Common finite difference schemes for PARTIAL DIFFERENTIAL EQUATIONS include the so-called Crank-Nicholson, Du Fort-Frankel, and Laasonen methods.

#### Finite Field

A finite field is a FIELD with a finite ORDER (number of elements), also called a GALOIS FIELD. The order of a finite field is always a PRIME or a POWER of a PRIME (Birkhoff and Mac Lane 1965). For each PRIME POWER, there exists exactly one (up to an ISOMORPHISM) finite field  $\text{GF}(p^n)$ , often written as  $\mathbb{F}_{p^n}$  in current usage.  $\text{GF}(p)$  is called the PRIME FIELD of order  $p$ , and is the FIELD of RESIDUE CLASSES modulo  $p$ , where the  $p$  elements are denoted  $0, 1, \dots, p-1$ .  $a = b$  in  $\text{GF}(p)$  means the same as  $a \equiv b \pmod{p}$ . Note, however, that  $2 \times 2 \equiv 0 \pmod{4}$  in the RING of residues modulo 4, so 2 has no reciprocal, and the RING of residues modulo 4 is distinct from the finite field with four elements. Finite fields are therefore denoted  $\text{GF}(p^n)$ , instead of  $\text{GF}(p_1 \cdots p_n)$  for clarity.

The finite field  $\text{GF}(2)$  consists of elements 0 and 1 which satisfy the following addition and multiplications tables.

+	0	1
0	0	1
1	1	0

×	0	1
0	0	0
1	0	1

If a subset  $S$  of the elements of a finite field  $F$  satisfies the above AXIOMS with the same operators of  $F$ , then  $S$

is called a SUBFIELD. Finite fields are used extensively in the study of ERROR-CORRECTING CODES.

When  $n > 1$ ,  $\text{GF}(p^n)$  can be represented as the FIELD of EQUIVALENCE CLASSES of POLYNOMIALS whose COEFFICIENTS belong to  $\text{GF}(p)$ . Any IRREDUCIBLE POLYNOMIAL of degree  $n$  yields the same FIELD up to an ISOMORPHISM. For example, for  $\text{GF}(2^3)$ , the modulus can be taken as  $x^3 + x^2 + 1 = 0$ ,  $x^3 + x + 1$ , or any other IRREDUCIBLE POLYNOMIAL of degree 3. Using the modulus  $x^3 + x + 1$ , the elements of  $\text{GF}(2^3)$ —written  $0, x^0, x^1, \dots$ —can be represented as POLYNOMIALS with degree less than 3. For instance,

$$\begin{aligned} x^3 &\equiv -x - 1 \equiv x + 1 \\ x^4 &\equiv x(x^3) \equiv x(x + 1) \equiv x^2 + x \\ x^5 &\equiv x(x^2 + x) \equiv x^3 + x^2 \equiv x^2 - x - 1 \equiv x^2 + x + 1 \\ x^6 &\equiv x(x^2 + x + 1) \equiv x^3 + x^2 + x \equiv x^2 - 1 \equiv x^2 + 1 \\ x^7 &\equiv x(x^2 + 1) \equiv x^3 + x \equiv -1 \equiv 1 \equiv x_0. \end{aligned}$$

Now consider the following table which contains several different representations of the elements of a finite field. The columns are the power, polynomial representation, triples of polynomial representation COEFFICIENTS (the vector representation), and the binary INTEGER corresponding to the vector representation (the regular representation).

Power	Representation		
	Polynomial	Vector	Regular
0	0	(000)	0
$x^0$	1	(001)	1
$x^1$	$x$	(010)	2
$x^2$	$x^2$	(100)	4
$x^3$	$x + 1$	(011)	3
$x^4$	$x^2 + x$	(110)	6
$x^5$	$x^2 + x + 1$	(111)	7
$x^6$	$x^2 + 1$	(101)	5

The set of POLYNOMIALS in the second column is closed under ADDITION and MULTIPLICATION modulo  $x^3 + x + 1$ , and these operations on the set satisfy the AXIOMS of finite field. This particular finite field is said to be an extension field of degree 3 of  $\text{GF}(2)$ , written  $\text{GF}(2^3)$ , and the field  $\text{GF}(2)$  is called the base field of  $\text{GF}(2^3)$ . If an IRREDUCIBLE POLYNOMIAL generates all elements in this way, it is called a PRIMITIVE IRREDUCIBLE POLYNOMIAL. For any PRIME or PRIME POWER  $q$  and any POSITIVE INTEGER  $n$ , there exists a PRIMITIVE IRREDUCIBLE POLYNOMIAL of degree  $n$  over  $\text{GF}(q)$ .

For any element  $c$  of  $\text{GF}(q)$ ,  $c^q = c$ , and for any NON-ZERO element  $d$  of  $\text{GF}(q)$ ,  $d^{q-1} = 1$ . There is a smallest POSITIVE INTEGER  $n$  satisfying the sum condition  $n \cdot 1 = 0$  in  $\text{GF}(q)$ , which is called the characteristic of the finite field  $\text{GF}(q)$ . The characteristic is a PRIME NUMBER for every finite field, and it is true that

$$(x + y)^p = x^p + y^p$$

over a finite field with characteristic  $p$ .

# Finite Group

A GROUP of finite ORDER. Examples of finite groups are the MODULO MULTIPLICATION GROUPS and the POINT GROUPS. The CLASSIFICATION THEOREM of finite SIMPLE GROUPS states that the finite SIMPLE GROUPS can be classified completely into one of five types.

There is no known FORMULA to give the number of possible finite groups as a function of the ORDER  $h$ . It is possible, however, to determine the number of ABELIAN GROUPS using the KRONECKER DECOMPOSITION THEOREM, and there is at least one ABELIAN GROUP for every finite order  $h$ .

The following table gives the numbers and names of the first few groups of ORDER  $h$ . In the table,  $N_{NA}$  denotes the number of non-Abelian groups,  $N_A$  denotes the number of ABELIAN GROUPS, and  $N$  the total number of groups. In addition,  $Z_n$  denotes an CYCLIC GROUP of ORDER  $n$ ,  $A_n$  an ALTERNATING GROUP,  $D_n$  a DIHEDRAL GROUP,  $Q_8$  the group of the QUATERNIONS,  $T$  the cubic group, and  $\otimes$  a DIRECT PRODUCT.

$h$	Name	$N_{NA}$	$N_A$	$N$
1	$\langle e \rangle$	1	0	1
2	$Z_2$	1	0	1
3	$Z_3$	1	0	1
4	$Z_2 \otimes Z_2, Z_4$	2	0	2
5	$Z_5$	1	0	1
6	$Z_6, D_3$	1	1	2
7	$Z_7$	1	0	1
8	$Z_2 \otimes Z_2 \otimes Z_2, Z_2 \otimes Z_4, Z_8, Q_8, D_4$	3	2	5
9	$Z_3 \otimes Z_3, Z_9$	2	0	2
10	$Z_{10}, D_5$	1	1	2
11	$Z_{11}$	1	0	1
12	$Z_2 \otimes Z_6, Z_{12}, A_4, D_6, T$	2	3	5
13	$Z_{13}$	1	0	1
14	$Z_{14}, D_7$	1	1	2
15	$Z_{15}$	1	0	1

Miller (1930) gave the number of groups for orders 1–100, including an erroneous 297 as the number of groups of ORDER 64. Senior and Lunn (1934, 1935) subsequently completed the list up to 215, but omitted 128 and 192. The number of groups of ORDER 64 was corrected in Hall and Senior (1964). James *et al.* (1990) found 2328 groups in 115 ISOCINISM families of ORDER 128, correcting previous work, and O'Brien (1991) found the number of groups of ORDER 256. The number of groups is known for orders up to 1000, with the possible exception of 512 and 768. Besche and Eick (1998) have determined the number of finite groups of orders less than 1000 which are not powers of 2 or 3. These numbers appear in the *Magma*<sup>®</sup> database. The numbers of nonisomorphic finite groups  $N$  of each ORDER  $h$  for the first few hundred orders are given in the following table (Sloane's A000001—the very first sequence).

The number of ABELIAN GROUPS of ORDER  $h$  is denoted  $N_A$  (Sloane's A000688). The smallest order for which there exist  $n = 1, 2, \dots$  nonisomorphic groups are 1, 4, 75, 28, 8, 42, ... (Sloane's A046057). The incrementally largest number of nonisomorphic finite groups are 1, 2, 5, 14, 15, 51, 52, 267, 2328, ... (Sloane's A046058), which occur for orders 1, 4, 8, 16, 24, 32, 48, 64, 128, ... (Sloane's A046059).

### Finite Group— $D_3$

The DIHEDRAL GROUP  $D_3$  is one of the two groups of ORDER 6. It is the non-Abelian group of smallest ORDER. Examples of  $D_3$  include the POINT GROUPS known as  $C_{3h}$ ,  $C_{3v}$ ,  $S_3$ ,  $D_3$ , the symmetry group of the EQUILATERAL TRIANGLE, and the group of permutation of three

objects. Its elements  $A_i$  satisfy  $A_i^3 = 1$ , and four of its elements satisfy  $A_i^2 = 1$ , where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$D_3$	1	A	B	C	D	E
1	1	A	B	C	D	E
A	A	1	D	E	B	C
B	B	E	1	D	C	A
C	C	D	E	1	A	B
D	D	C	A	B	E	1
E	E	B	C	A	1	D

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A, B, C\}$

$$A^{-1}AA = A \quad (1)$$

$$B^{-1}AB = C \quad (2)$$

$$C^{-1}AC = B \quad (3)$$

$$D^{-1}AD = C \quad (4)$$

$$E^{-1}AE = B, \quad (5)$$

and  $\{D, E\}$ ,

$$DA^{-1}D = E \quad (6)$$

$$B^{-1}DB = D. \quad (7)$$

A reducible 2-D representation using REAL MATRICES can be found by performing the spatial rotations corresponding to the symmetry elements of  $C_{3v}$ . Take the z-AXIS along the  $C_3$  axis.

$$I = R_z(0) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (8)$$

$$A = R_z\left(\frac{2}{3}\pi\right) = \begin{bmatrix} \cos\left(\frac{2}{3}\pi\right) & \sin\left(\frac{2}{3}\pi\right) \\ -\sin\left(\frac{2}{3}\pi\right) & \cos\left(\frac{2}{3}\pi\right) \end{bmatrix} \\ = \begin{bmatrix} -\frac{1}{2} & -\frac{1}{2}\sqrt{3} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (9)$$

$$B = R_z\left(\frac{4}{3}\pi\right) = \begin{bmatrix} -\frac{1}{2} & \frac{1}{2}\sqrt{3} \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (10)$$

$$C = R_C(\pi) = \begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} \quad (11)$$

$$D = R_D(\pi) = CB = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2}\sqrt{3} \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix} \quad (12)$$

$$E = R_E(\pi) = CA = \begin{bmatrix} \frac{1}{2} & \frac{1}{2}\sqrt{3} \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} \end{bmatrix}. \quad (13)$$

To find the irreducible representation, note that there are three CONJUGACY CLASSES. Rule 5 requires that there be three irreducible representations satisfying

$$h = l_1^2 + l_2^2 + l_3^2 = 6, \quad (14)$$

so it must be true that

$$l_1 = l_2 = 1, l_3 = 2. \quad (15)$$

By rule 6, we can let the first representation have all 1s.

$D_3$	1	A	B	C	D	E
$\Gamma_1$	1	1	1	1	1	1

To find representation orthogonal to the totally symmetric representation, we must have three +1 and three -1 CHARACTERS. We can also add the constraint that the components of the IDENTITY ELEMENT 1 be positive. The three CONJUGACY CLASSES have 1, 2, and 3 elements. Since we need a total of three +1s and we have required that a +1 occur for the CONJUGACY CLASS of ORDER 1, the remaining +1s must be used for the elements of the CONJUGACY CLASS of ORDER 2, i.e., A and B.

$D_3$	1	A	B	C	D	E
$\Gamma_1$	1	1	1	1	1	1
$\Gamma_2$	1	1	1	-1	-1	-1

Using the rule 1, we see that

$$1^2 + 1^2 + \chi_3^2(1) = 6, \quad (16)$$

so the final representation for 1 has CHARACTER 2. Orthogonality with the first two representations (rule 3) then yields the following constraints:

$$1 \cdot 1 \cdot 2 + 1 \cdot 2 \cdot \chi_2 + 1 \cdot 3 \cdot \chi_3 = 2 + 2\chi_2 + 3\chi_3 = 0 \quad (17)$$

$$1 \cdot 1 \cdot 2 + 1 \cdot 2 \cdot \chi_2 + (-1) \cdot 3 \cdot \chi_3 = 2 + 2\chi_2 - 3\chi_3 = 0. \quad (18)$$

Solving these simultaneous equations by adding and subtracting (18) from (17), we obtain  $\chi_2 = -1$ ,  $\chi_3 = 0$ . The full CHARACTER TABLE is then

$D_3$	1	A	B	C	D	E
$\Gamma_1$	1	1	1	1	1	1
$\Gamma_2$	1	1	1	-1	-1	-1
$\Gamma_3$	2	-1	-1	0	0	0

Since there are only three CONJUGACY CLASSES, this table is conventionally written simply as

$D_3$	1	A = B	C = D = E
$\Gamma_1$	1	1	1
$\Gamma_2$	1	1	-1
$\Gamma_3$	2	-1	0

Writing the irreducible representations in matrix form then yields

$$1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (19)$$

$$A = \begin{bmatrix} -\frac{1}{2} & -\frac{1}{2}\sqrt{3} & 0 & 0 \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (20)$$

$$B = \begin{bmatrix} -\frac{1}{2} & \frac{1}{2}\sqrt{3} & 0 & 0 \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (21)$$

$$C = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (22)$$

$$D = \begin{bmatrix} \frac{1}{2} & -\frac{1}{2}\sqrt{3} & 0 & 0 \\ -\frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (23)$$

$$E = \begin{bmatrix} \frac{1}{2} & \frac{1}{2}\sqrt{3} & 0 & 0 \\ \frac{1}{2}\sqrt{3} & -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}. \quad (24)$$

see also DIHEDRAL GROUP, FINITE GROUP— $D_4$ , FINITE GROUP— $Z_6$

### Finite Group— $D_4$

The DIHEDRAL GROUP  $D_4$  is one of the two non-Abelian groups of the five groups total of ORDER 8. It is sometimes called the octic group. Examples of  $D_4$  include the symmetry group of the SQUARE. The CYCLE GRAPH is shown above.

see also DIHEDRAL GROUP, FINITE GROUP— $D_3$ , FINITE GROUP— $Z_8$ , FINITE GROUP— $Z_2 \otimes Z_2 \otimes Z_2$ , FINITE GROUP— $Z_2 \otimes Z_4$ , FINITE GROUP— $Z_8$ ,

### Finite Group— $\langle e \rangle$

The unique (and trivial) group of ORDER 1 is denoted  $\langle e \rangle$ . It is (trivially) ABELIAN and CYCLIC. Examples include the POINT GROUP  $C_1$  and the integers modulo 1 under addition.

$$\begin{array}{c|c} \langle e \rangle & 1 \\ \hline 1 & 1 \end{array}$$

The only class is  $\{1\}$ .

### Finite Group— $Q_8$

One of the three Abelian groups of the five groups total of ORDER 8. The group  $Q_8$  has the MULTIPLICATION TABLE of  $\pm 1, i, j, k$ , where 1,  $i$ ,  $j$ , and  $k$  are the QUATERNIONS. The CYCLE GRAPH is shown above.

see also FINITE GROUP— $D_4$ , FINITE GROUP— $Z_2 \otimes Z_2 \otimes Z_2$ , FINITE GROUP— $Z_2 \otimes Z_4$ , FINITE GROUP— $Z_8$ , QUATERNION

### Finite Group— $Z_2$

The unique group of ORDER 2.  $Z_2$  is both ABELIAN and CYCLIC. Examples include the POINT GROUPS  $C_s$ ,  $C_i$ , and  $C_2$ , the integers modulo 2 under addition, and the MODULO MULTIPLICATION GROUPS  $M_3$ ,  $M_4$ , and  $M_6$ . The elements  $A_i$  satisfy  $A_i^2 = 1$ , where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$Z_2$	1	A
1	1	A
A	A	1

The CONJUGACY CLASSES are  $\{1\}$  and  $\{A\}$ . The irreducible representation for the  $C_2$  group is  $\{1, -1\}$ .

### Finite Group— $Z_2 \otimes Z_2$

One of the two groups of ORDER 4. The name of this group derives from the fact that it is a DIRECT PRODUCT of two  $Z_2$  SUBGROUPS. Like the group  $Z_4$ ,  $Z_2 \otimes Z_2$  is an ABELIAN GROUP. Unlike  $Z_4$ , however, it is not CYCLIC. In addition to satisfying  $A_i^4 = 1$  for each element  $A_i$ , it also satisfies  $A_i^2 = 1$ , where 1 is the IDENTITY ELEMENT. Examples of the  $Z_2 \otimes Z_2$  group include the VIERGRUPPE, POINT GROUPS  $D_2$ ,  $C_{2h}$ , and  $C_{2v}$ , and the MODULO MULTIPLICATION GROUPS  $M_8$  and  $M_{12}$ . That  $M_8$ , the RESIDUE CLASSES prime to 8 given by  $\{1, 3, 5, 7\}$ , are a group of type  $Z_2 \otimes Z_2$  can be shown by verifying that

$$\begin{aligned} 1^2 = 1 \quad 3^2 = 9 \equiv 1 \quad 5^2 = 25 \equiv 1 \quad 7^2 \\ = 49 \equiv 1 \pmod{8} \end{aligned} \quad (1)$$

and

$$\begin{aligned} 3 \cdot 5 = 15 \equiv 7 \quad 3 \cdot 7 = 21 \equiv 5 \quad 5 \cdot 7 = 35 \equiv 3 \pmod{8}. \end{aligned} \quad (2)$$

$Z_2 \otimes Z_2$  is therefore a MODULO MULTIPLICATION GROUP.

The CYCLE GRAPH is shown above, and the multiplication table for the  $Z_2 \otimes Z_2$  group is given below.

$Z_2 \otimes Z_2$	1	A	B	C
1	1	A	B	C
A	A	1	C	B
B	B	C	1	A
C	C	B	A	1

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A\}$ ,

$$A^{-1}AA = A \quad (3)$$

$$B^{-1}AB = A \quad (4)$$

$$C^{-1}AC = A, \quad (5)$$

$\{B\}$ ,

$$A^{-1}BA = B \quad (6)$$

$$C^{-1}BC = B, \quad (7)$$

and  $\{C\}$ .

Now explicitly consider the elements of the  $C_{2v}$  POINT GROUP.

$C_{2v}$	E	$C_2$	$\sigma_v$	$\sigma'_v$
E	E	$C_2$	$\sigma_v$	$\sigma'_v$
$C_2$	$C_2$	E	$\sigma'_v$	$\sigma_v$
$\sigma_v$	$\sigma_v$	$\sigma'_v$	E	$C_2$
$\sigma'_v$	$\sigma'_v$	$\sigma_v$	$C_2$	E

In terms of the VIERGRUPPE elements

V	I	$V_1$	$V_2$	$V_3$
I	I	$V_1$	$V_2$	$V_3$
$V_1$	$V_1$	I	$V_3$	$V_2$
$V_2$	$V_2$	$V_3$	I	$V_1$
$V_3$	$V_3$	$V_2$	$V_1$	I

A reducible representation using 2-D REAL MATRICES is

$$1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (8)$$

$$A = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \quad (9)$$

$$B = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \quad (10)$$

$$C = \begin{bmatrix} 0 & -1 \\ -1 & 0 \end{bmatrix}. \quad (11)$$

Another reducible representation using 3-D REAL MATRICES can be obtained from the symmetry elements of the  $D_2$  group ( $1$ ,  $C_2(z)$ ,  $C_2(y)$ , and  $C_2(x)$ ) or  $C_{2v}$  group

( $1$ ,  $C_2$ ,  $\sigma_v$ , and  $\sigma'_v$ ). Place the  $C_2$  axis along the  $z$ -axis,  $\sigma_v$  in the  $x$ - $y$  plane, and  $\sigma'_v$  in the  $y$ - $z$  plane.

$$1 = E = E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (12)$$

$$A = R_x(\pi) = \sigma_v = \begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (13)$$

$$C = R_z(\pi) = C_2 = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (14)$$

$$B = R_y(\pi) = \sigma'_v = \begin{bmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (15)$$

In order to find the irreducible representations, note that the traces are given by  $\chi(1) = 3$ ,  $\chi(C_2) = -1$ , and  $\chi(\sigma_v) = \chi(\sigma'_v) = 1$ . Therefore, there are at least three distinct CONJUGACY CLASSES. However, we see from the MULTIPLICATION TABLE that there are actually four CONJUGACY CLASSES, so group rule 5 requires that there must be four irreducible representations. By rule 1, we are looking for POSITIVE INTEGERS which satisfy

$$l_1^2 + l_2^2 + l_3^2 + l_4^2 = 4. \quad (16)$$

The only combination which will work is

$$l_1 = l_2 = l_3 = l_4 = 1, \quad (17)$$

so there are four one-dimensional representations. Rule 2 requires that the sum of the squares equal the ORDER  $h = 4$ , so each 1-D representation must have CHARACTER  $\pm 1$ . Rule 6 requires that a totally symmetric representation always exists, so we are free to start off with the first representation having all 1s. We then use orthogonality (rule 3) to build up the other representations. The simplest solution is then given by

$C_{2v}$	1	$C_2$	$\sigma_v$	$\sigma'_v$
$\Gamma_1$	1	1	1	1
$\Gamma_2$	1	-1	-1	1
$\Gamma_3$	1	-1	1	-1
$\Gamma_4$	1	1	-1	-1

These can be put into a more familiar form by switching  $\Gamma_1$  and  $\Gamma_3$ , giving the CHARACTER TABLE

$C_{2v}$	1	$C_2$	$\sigma_v$	$\sigma'_v$
$\Gamma_3$	1	-1	1	-1
$\Gamma_2$	1	-1	-1	1
$\Gamma_1$	1	1	1	1
$\Gamma_4$	1	1	-1	-1

The matrices corresponding to this representation are now

$$1 = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (18)$$

$$C_2 = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (19)$$

$$\sigma_v = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \quad (20)$$

$$\sigma'_v = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}, \quad (21)$$

which consist of the previous representation with an additional component. These matrices are now orthogonal, and the order equals the matrix dimension. As before,  $\chi(\sigma_v) = \chi(\sigma'_v)$ .

see also FINITE GROUP— $Z_4$

#### Finite Group— $Z_2 \otimes Z_2 \otimes Z_2$

One of the three Abelian groups of the five groups total of ORDER 8. Examples include the MODULO MULTIPLICATION GROUP  $M_{24}$ . The elements  $A_i$  of this group satisfy  $A_i^2 = 1$ , where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above.

see also FINITE GROUP— $D_4$ , FINITE GROUP— $Q_8$ , FINITE GROUP— $Z_2 \otimes Z_4$ , FINITE GROUP— $Z_8$

#### Finite Group— $Z_2 \otimes Z_4$

One of the three Abelian groups of the five groups total of ORDER 8. Examples include the MODULO MULTIPLICATION GROUPS  $M_{15}$ ,  $M_{16}$ ,  $M_{20}$ , and  $M_{30}$ . The elements  $A_i$  of this group satisfy  $A_i^4 = 1$ , where 1 is the IDENTITY ELEMENT, and four of the elements satisfy  $A_i^2 = 1$ . The CYCLE GRAPH is shown above.

see also FINITE GROUP— $D_4$ , FINITE GROUP— $Q_8$ , FINITE GROUP— $Z_2 \otimes Z_2 \otimes Z_2$ , FINITE GROUP— $Z_8$

#### Finite Group— $Z_3$

The unique group of ORDER 3. It is both ABELIAN and CYCLIC. Examples include the POINT GROUPS  $C_3$  and  $D_3$  and the integer modulo 3. The elements  $A_i$  of the group satisfy  $A_i^3 = 1$  where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$Z_3$	1	A	B
1	1	A	B
A	A	B	1
B	B	1	A

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A\}$ ,

$$A^{-1}AA = A$$

$$B^{-1}AB = A,$$

and  $\{B\}$ ,

$$A^{-1}BA = B$$

$$B^{-1}BB = B.$$

The irreducible representation (CHARACTER TABLE) is therefore

$\Gamma$	1	A	B
$\Gamma_1$	1	1	1
$\Gamma_2$	1	1	-1
$\Gamma_3$	1	-1	1

#### Finite Group— $Z_4$

One of the two groups of ORDER 4. Like  $Z_2 \otimes Z_2$ , it is ABELIAN, but unlike  $Z_2 \otimes Z_2$ , it is a CYCLIC. Examples include the POINT GROUPS  $C_4$  and  $S_4$  and the MODULO MULTIPLICATION GROUPS  $M_5$  and  $M_{10}$ . Elements  $A_i$  of the group satisfy  $A_i^4 = 1$ , where 1 is the IDENTITY ELEMENT, and two of the elements satisfy  $A_i^2 = 1$ .

The CYCLE GRAPH is shown above. The MULTIPLICATION TABLE for this group may be written in three equivalent ways—denoted here by  $Z_4^{(1)}$ ,  $Z_4^{(2)}$ , and  $Z_4^{(3)}$ —by permuting the symbols used for the group elements.

$Z_4^{(1)}$	1	A	B	C
1	1	A	B	C
A	A	B	C	1
B	B	C	1	A
C	C	1	A	B

The MULTIPLICATION TABLE for  $Z_4^{(2)}$  is obtained from  $Z_4^{(1)}$  by interchanging  $A$  and  $B$ .

$Z_4^{(2)}$	1	A	B	C
1	1	A	B	C
A	A	1	C	B
B	B	C	A	1
C	C	B	1	A

The MULTIPLICATION TABLE for  $Z_4^{(3)}$  is obtained from  $Z_4^{(1)}$  by interchanging  $A$  and  $C$ .

$Z_4^{(3)}$	1	A	B	C
1	1	A	B	C
A	A	C	1	B
B	B	1	C	A
C	C	B	A	1

The CONJUGACY CLASSES of  $Z_4$  are  $\{1\}$ ,  $\{A\}$ ,

$$A^{-1}AA = A \quad (1)$$

$$B^{-1}AB = A \quad (2)$$

$$C^{-1}AC = A, \quad (3)$$

$\{B\}$ ,

$$A^{-1}BA = B \quad (4)$$

$$B^{-1}BB = B \quad (5)$$

$$C^{-1}BC = B, \quad (6)$$

and  $\{C\}$ .

The group may be given a reducible representation using COMPLEX NUMBERS

$$1 = 1 \quad (7)$$

$$A = i \quad (8)$$

$$B = -1 \quad (9)$$

$$C = -i, \quad (10)$$

or REAL MATRICES

$$1 = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad (11)$$

$$A = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \quad (12)$$

$$B = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix} \quad (13)$$

$$C = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}. \quad (14)$$

see also FINITE GROUP— $Z_2 \otimes Z_2$

**Finite Group— $Z_5$** 

The unique GROUP of ORDER 5, which is ABELIAN. Examples include the POINT GROUP  $C_5$  and the integers mod 5 under addition. The elements  $A_i$  satisfy  $A_i^5 = 1$ , where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is illustrated below.

$Z_5$	1	A	B	C	D
1	1	A	B	C	D
A	A	B	C	D	1
B	B	C	D	1	A
C	C	D	1	A	B
D	D	1	A	B	C

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A\}$ ,  $\{B\}$ ,  $\{C\}$ , and  $\{D\}$ .

**Finite Group— $Z_6$** 

One of the two groups of ORDER 6 which, unlike  $D_3$ , is ABELIAN. It is also a CYCLIC. It is isomorphic to  $Z_2 \otimes Z_3$ . Examples include the POINT GROUPS  $C_6$  and  $S_6$ , the integers modulo 6 under addition, and the MODULO MULTIPLICATION GROUPS  $M_7$ ,  $M_9$ , and  $M_{14}$ . The elements  $A_i$  of the group satisfy  $A_i^6 = 1$ , where 1 is the IDENTITY ELEMENT, three elements satisfy  $A_i^3 = 1$ , and two elements satisfy  $A_i^2 = 1$ . The CYCLE GRAPH is shown above, and the MULTIPLICATION TABLE is given below.

$Z_6$	1	A	B	C	D	E
1	1	A	B	C	D	E
A	A	1	E	D	B	C
B	B	E	1	A	C	D
C	C	D	A	1	E	B
D	D	B	C	E	1	A
E	E	C	D	B	A	1

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A\}$ ,  $\{B\}$ ,  $\{C\}$ ,  $\{D\}$ , and  $\{E\}$ .

see also FINITE GROUP— $D_3$

Finite Group— $Z_7$ 

The unique GROUP of ORDER 7. It is ABELIAN and CYCLIC. Examples include the POINT GROUP  $C_7$  and the integers modulo 7 under addition. The elements  $A_i$  of the group satisfy  $A_i^7 = 1$ , where 1 is the IDENTITY ELEMENT. The CYCLE GRAPH is shown above.

$Z_7$	1	A	B	C	D	E	F
1	1	A	B	C	D	E	F
A	A	B	C	D	E	F	1
B	B	C	D	E	F	1	A
C	C	D	E	F	1	A	B
D	D	E	F	1	A	B	C
E	E	F	1	A	B	C	D
F	F	1	A	B	C	D	E

The CONJUGACY CLASSES are  $\{1\}$ ,  $\{A\}$ ,  $\{B\}$ ,  $\{C\}$ ,  $\{D\}$ ,  $\{E\}$ , and  $\{F\}$ .

Finite Group— $Z_8$ 

One of the three Abelian groups of the five groups total of ORDER 8. An example is the residue classes modulo 17 which QUADRATIC RESIDUES, i.e.,  $\{1, 2, 4, 8, 9, 13, 15, 16\}$  under multiplication modulo 17. The elements  $A_i$  satisfy  $A_i^8 = 1$ , four of them satisfy  $A_i^4 = 1$ , and two satisfy  $A_i^2 = 1$ . The CYCLE GRAPH is shown above.

see also FINITE GROUP— $D_4$ , FINITE GROUP— $Q_8$ , FINITE GROUP— $Z_2 \otimes Z_4$ , FINITE GROUP— $Z_2 \otimes Z_2 \otimes Z_2$

## Finite Mathematics

The branch of mathematics which does not involve infinite sets, limits, or continuity.

see also COMBINATORICS, DISCRETE MATHEMATICS

## Finite Simple Group

see SIMPLE GROUP

## Finite Simple Group Classification Theorem

see CLASSIFICATION THEOREM

## Finite-to-One Factor

A MAP  $\psi : M \rightarrow M$ , where  $M$  is a MANIFOLD, is a finite-to-one factor of a MAP  $\Psi : X \rightarrow X$  if there exists a continuous ONTO MAP  $\pi : X \rightarrow M$  such that  $\psi \circ \pi = \pi \circ \Psi$  and  $\pi^{-1}(x) \subset X$  is finite for each  $x \in M$ .

## Finsler Geometry

The geometry of FINSLER SPACE.

## Finsler Manifold

see FINSLER SPACE

## Finsler Metric

A continuous real function  $L(x, y)$  defined on the TANGENT BUNDLE  $T(M)$  of an  $n$ -D DIFFERENTIABLE MANIFOLD  $M$  is said to be a Finsler metric if

1.  $L(x, y)$  is DIFFERENTIABLE at  $x \neq y$ ,
2.  $L(x, \lambda y) = |\lambda|L(x, y)$  for any element  $(x, y) \in T(M)$  and any REAL NUMBER  $\lambda$ ,
3. Denoting the METRIC

$$g_{ij}(x, y) = \frac{1}{2} \frac{\partial^2 [L(x, y)]^2}{\partial y^i \partial y^j},$$

then  $g_{ij}$  is a POSITIVE DEFINITE MATRIX.

A DIFFERENTIABLE MANIFOLD  $M$  with a Finsler metric is called a FINSLER SPACE.

see also DIFFERENTIABLE MANIFOLD, FINSLER SPACE, TANGENT BUNDLE

## Finsler Space

A general space based on the LINE ELEMENT

$$ds = F(x^1, \dots, x^n; dx^1, \dots, dx^n),$$

with  $F(x, y) > 0$  for  $y \neq 0$  a function on the TANGENT BUNDLE  $T(M)$ , and homogeneous of degree 1 in  $y$ . Formally, a Finsler space is a DIFFERENTIABLE MANIFOLD possessing a FINSLER METRIC. Finsler geometry is RIEMANNIAN GEOMETRY *without* the restriction that the LINE ELEMENT be quadratic of the form

$$F^2 = g_{ij}(x) dx^i dx^j.$$

A compact boundaryless Finsler space is locally Minkowskian IFF it has 0 "flag curvature."

see also FINSLER METRIC, HODGE'S THEOREM, RIEMANNIAN GEOMETRY, TANGENT BUNDLE

### Finsler-Hadwiger Theorem

Let the SQUARES  $\square ABCD$  and  $\square AB'C'D'$  share a common VERTEX  $A$ . The midpoints  $Q$  and  $S$  of the segments  $B'D$  and  $BD'$  together with the centers of the original squares  $R$  and  $T$  then form another square  $\square QRST$ . This theorem is a special case of the FUNDAMENTAL THEOREM OF DIRECTLY SIMILAR FIGURES (Detemple and Harold 1996).

see also FUNDAMENTAL THEOREM OF DIRECTLY SIMILAR FIGURES, SQUARE

### First-Countable Space

A TOPOLOGICAL SPACE in which every point has a countable BASE for its neighborhood system.

### First Curvature

see CURVATURE

### First Derivative Test

Suppose  $f(x)$  is CONTINUOUS at a STATIONARY POINT  $x_0$ .

1. If  $f'(x) > 0$  on an OPEN INTERVAL extending left from  $x_0$  and  $f'(x) < 0$  on an OPEN INTERVAL extending right from  $x_0$ , then  $f$  has a RELATIVE MAXIMUM (possibly a GLOBAL MAXIMUM) at  $x_0$ .
2. If  $f'(x) < 0$  on an OPEN INTERVAL extending left from  $x_0$  and  $f'(x) > 0$  on an OPEN INTERVAL extending right from  $x_0$ , then  $f$  has a RELATIVE MINIMUM (possibly a GLOBAL MINIMUM) at  $x_0$ .
3. If  $f'(x)$  has the same sign on an OPEN INTERVAL extending left from  $x_0$  and on an OPEN INTERVAL extending right from  $x_0$ , then  $f$  does not have a RELATIVE EXTREMUM at  $x_0$ .

### First Multiplier Theorem

Let  $D$  be a planar Abelian DIFFERENCE SET and  $t$  be any DIVISOR of  $n$ . Then  $t$  is a numerical multiplier of  $D$ , where a multiplier is defined as an automorphism  $\alpha$  of  $G$  which takes  $D$  to a translation  $g + D$  of itself for some  $g \in G$ . If  $\alpha$  is of the form  $\alpha : x \rightarrow tx$  for  $t \in \mathbb{Z}$  relatively prime to the order of  $G$ , then  $\alpha$  is called a numerical multiplier.

**Fisher's Estimator Inequality**

Given  $T$  an UNBIASED ESTIMATOR of  $\theta$  so that  $\langle T \rangle = \theta$ . Then

$$\text{var}(T) \geq \frac{1}{N \int_{-\infty}^{\infty} \left[ \frac{\partial(\ln f)}{\partial \theta} \right]^2 f dx},$$

where var is the VARIANCE.

**Fisher's Exact Test**

A STATISTICAL TEST used to determine if there are non-random associations between two CATEGORICAL VARIABLES. Let there exist two such variables  $X$  and  $Y$ , with  $m$  and  $n$  observed states, respectively. Now form an  $n \times m$  MATRIX in which the entries  $a_{ij}$  represent the number of observations in which  $x = i$  and  $y = j$ . Calculate the row and column sums  $R_i$  and  $C_j$ , respectively, and the total sum

$$N = \sum_i R_i = \sum_j C_j$$

of the MATRIX. Then calculate the conditional LIKELIHOOD ( $P$ -VALUE) of getting the actual matrix given the particular row and column sums, given by

$$P_{\text{crit}} = \frac{(R_1! R_2! \cdots R_m!)(C_1! C_2! \cdots C_n!)}{N! \prod_{i,j} a_{ij}!}$$

(which is a HYPERGEOMETRIC DISTRIBUTION). Now find all possible MATRICES of NONNEGATIVE INTEGERS consistent with the row and column sums  $R_i$  and  $C_j$ . For each one, calculate the associated  $P$ -VALUE using (0) (where the sum of these probabilities must be 1). Then the  $P$ -VALUE of the test is given by the sum of all  $P$ -VALUES which are  $\leq P_{\text{crit}}$ .

The test is most commonly applied to a  $2 \times 2$  MATRICES, and is computationally unwieldy for large  $m$  or  $n$ .

As an example application of the test, let  $X$  be a journal, say either *Mathematics Magazine* or *Science*, and let  $Y$  be the number of articles on the topics of mathematics and biology appearing in a given issue of one of these journals. If *Mathematics Magazine* has five articles on math and one on biology, and *Science* has none on math and four on biology, then the relevant matrix would be

	<i>Math. Mag.</i>	<i>Science</i>	
math	5	0	$R_1 = 5$
biology	1	4	$R_2 = 5$
	$C_1 = 6$	$C_2 = 4$	$N = 10$ .

Computing  $P_{\text{crit}}$  gives

$$P_{\text{crit}} = \frac{5!26!4!}{10!(5!0!1!4!)} = 0.0238,$$

and the other possible matrices and their  $P$ s are

$$\begin{array}{ll} \begin{bmatrix} 4 & 1 \\ 2 & 3 \end{bmatrix} & P = 0.2381 \\ \begin{bmatrix} 3 & 2 \\ 3 & 2 \end{bmatrix} & P = 0.4762 \\ \begin{bmatrix} 2 & 3 \\ 4 & 1 \end{bmatrix} & P = 0.2381 \\ \begin{bmatrix} 1 & 4 \\ 5 & 0 \end{bmatrix} & P = 0.0238, \end{array}$$

which indeed sum to 1, as required. The sum of  $P$ -values less than or equal to  $P_{\text{crit}} = 0.0238$  is then 0.0476 which, because it is less than 0.05, is SIGNIFICANT. Therefore, in this case, there would be a statistically significant association between the journal and type of article appearing.

**Fisher Index**

The statistical INDEX

$$P_B = \sqrt{P_L P_P},$$

where  $P_L$  is LASPEYRES' INDEX and  $P_P$  is PAASCHE'S INDEX.

see also INDEX

**References**

- Kenney, J. F. and Keeping, E. S. *Mathematics of Statistics, Pt. 1, 3rd ed.* Princeton, NJ: Van Nostrand, p. 66, 1962.

**Fisher Kurtosis**

$$\gamma_2 \equiv b_2 \equiv \frac{\mu_4}{\mu_2^2} - 3 = \frac{\mu_4}{\sigma^4} - 3,$$

where  $\mu_i$  is the  $i$ th MOMENT about the MEAN and  $\sigma = \sqrt{\mu_2}$  is the STANDARD DEVIATION.

see also FISHER SKEWNESS, KURTOSIS, PEARSON KURTOSIS

**Fisher Sign Test**

A robust nonparametric test which is an alternative to the PAIRED  $t$ -TEST. This test makes the basic assumption that there is information only in the signs of the differences between paired observations, not in their sizes. Take the paired observations, calculate the differences, and count the number of +s  $n_+$  and -s  $n_-$ , where

$$N \equiv n_+ + n_-$$

is the sample size. Calculate the BINOMIAL COEFFICIENT

$$B \equiv \binom{N}{n_+}.$$

Then  $B/2^N$  gives the probability of getting exactly this many +s and -s if POSITIVE and NEGATIVE values are equally likely. Finally, to obtain the  $P$ -VALUE for the test, sum all the COEFFICIENTS that are  $\leq B$  and divide by  $2^N$ .

see also HYPOTHESIS TESTING

**Fisher Skewness**

$$\gamma_1 = \frac{\mu_3}{\mu_2^{3/2}} = \frac{\mu_3}{\sigma^3},$$

where  $\mu_i$  is the  $i$  MOMENT about the MEAN, and  $\sigma = \sqrt{\mu_2}$  is the STANDARD DEVIATION.

see also FISHER KURTOSIS, MOMENT, SKEWNESS, STANDARD DEVIATION

**Fisher's Theorem**

Let  $A$  be a sum of squares of  $n$  independent normal standardized variates  $x_i$ , and suppose  $A = B + C$  where  $B$  is a quadratic form in the  $x_i$ , distributed as CHI-SQUARED with  $h$  DEGREES OF FREEDOM. Then  $C$  is distributed as  $\chi^2$  with  $n - h$  DEGREES OF FREEDOM and is independent of  $B$ . The converse of this theorem is known as COCHRAN'S THEOREM.

see also CHI-SQUARED DISTRIBUTION, COCHRAN'S THEOREM

**Fisher-Tippett Distribution**

Also called the EXTREME VALUE DISTRIBUTION and LOG-WEIBULL DISTRIBUTION. It is the limiting distribution for the smallest or largest values in a large sample drawn from a variety of distributions.

$$P(x) = \frac{e^{(a-x)/b - e^{(a-x)/b}}}{b} \quad (1)$$

$$D(x) = e^{-e^{(a-x)/b}}. \quad (2)$$

These can be computed directly by defining

$$z \equiv \exp\left(\frac{a-x}{b}\right) \quad (3)$$

$$x = a - b \ln z \quad (4)$$

$$dz = -\frac{1}{b} \exp\left(\frac{a-x}{b}\right) dx. \quad (5)$$

Then the MOMENTS are

$$\begin{aligned} \mu_n &\equiv \int_{-\infty}^{\infty} x^n P(x) dx \\ &= \frac{1}{b} \int_{-\infty}^{\infty} x^n \exp\left(\frac{a}{x-b}\right) \exp[-e^{(a-x)/b}] dx \\ &= - \int_{\infty}^0 (a - b \ln z)^n e^{-z} dz \\ &= \int_0^{\infty} (a - b \ln z)^n e^{-z} dz \\ &= \sum_{k=0}^n \binom{n}{k} (-1)^k a^{n-k} b^k \int_0^{\infty} (\ln z)^k e^{-z} dz \\ &= \sum_{k=0}^n \binom{n}{k} a^{n-k} b^k I(k), \end{aligned} \quad (6)$$

where  $I(k)$  are EULER-MASCHERONI INTEGRALS. Plugging in the EULER-MASCHERONI INTEGRALS  $I(k)$  gives

$$\mu_0 = 1 \quad (7)$$

$$\mu_1 = a + b\gamma \quad (8)$$

$$\mu_2 = a^2 + 2ab\gamma + b^2(\gamma^2 + \frac{1}{6}\pi^2) \quad (9)$$

$$\begin{aligned} \mu_3 &= a^3 + 3a^2b\gamma + 3ab^2(\gamma^2 + \frac{1}{6}\pi^2) \\ &\quad + b^3[\gamma^3 + \frac{1}{2}\gamma\pi^2 + 2\zeta(3)] \end{aligned} \quad (10)$$

$$\begin{aligned} \mu_4 &= a^4 + 4a^3b\gamma + 6a^2b^2(\gamma^2 + \frac{1}{6}\pi^2) \\ &\quad + 4ab^3[\gamma^3 + \frac{1}{2}\gamma\pi^2 + 2\zeta(3)] \\ &\quad + b^4[\gamma^4 + \gamma^2\pi^2 + \frac{3}{20}\pi^4 + 8\gamma\zeta(3)], \end{aligned} \quad (11)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\zeta(3)$  is APÉRY'S CONSTANT. The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are therefore

$$\mu = a + b\gamma \quad (12)$$

$$\sigma^2 = \mu_2 - \mu_1^2 = \frac{1}{6}\pi^2 b^2 \quad (13)$$

$$\begin{aligned} \gamma_1 &= \frac{\mu_3}{\sigma^3} \\ &= \frac{6\sqrt{6}}{b^3\pi^3} \left\{ a^3 + 3a^2b\gamma + 3ab^2(\gamma^2 + \frac{1}{6}\pi^2) \right. \\ &\quad \left. + b^3[\gamma^3 + \frac{1}{2}\gamma\pi^2 + 2\zeta(3)] \right\} \end{aligned} \quad (14)$$

$$\begin{aligned} \gamma_2 &= \frac{\mu_4}{\sigma^4} - 3 \\ &= \frac{36}{b^4\pi^4} \left\{ a^4 + 4a^3b\gamma + a^2b^2(6\gamma^2 + \pi^2) \right. \\ &\quad \left. + 4ab^3[\gamma^3 + \frac{1}{2}\gamma\pi^2 + 2\zeta(3)] \right. \\ &\quad \left. + b^4[\gamma^4 + \gamma^2\pi^2 + \frac{3}{20}\pi^4 + 8\gamma\zeta(3)] \right\}. \end{aligned} \quad (15)$$

The CHARACTERISTIC FUNCTION is

$$\phi(t) = \Gamma(1 - i\beta t)e^{iat}, \quad (16)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION. The special case of the Fisher-Tippett distribution with  $a = 0$ ,  $b = 1$  is called GUMBEL'S DISTRIBUTION.

see also EULER-MASCHERONI INTEGRALS, GUMBEL'S DISTRIBUTION

### Fisher's $z$ -Distribution

$$g(z) = \frac{2n_1^{n_1/2} n_2^{n_2/2}}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)} \frac{e^{n_1 z}}{(n_1 e^{2z} + n_2)^{(n_1+n_1)/2}} \quad (1)$$

(Kenney and Keeping 1951). This general distribution includes the CHI-SQUARED DISTRIBUTION and STUDENT'S  $t$ -DISTRIBUTION as special cases. Let  $u^2$  and  $v^2$  be INDEPENDENT UNBIASED ESTIMATORS of the VARIANCE of a NORMALLY DISTRIBUTED variate. Define

$$z \equiv \ln\left(\frac{u}{v}\right) = \frac{1}{2} \ln\left(\frac{u^2}{v^2}\right). \quad (2)$$

Then let

$$F \equiv \frac{u^2}{v^2} = \frac{Ns_1^2}{Ns_2^2} \quad (3)$$

so that  $n_1 F / n_2$  is a ratio of CHI-SQUARED variates

$$\frac{n_1 F}{n_2} = \frac{\chi^2(n_1)}{\chi^2(n_2)}, \quad (4)$$

which makes it a ratio of GAMMA DISTRIBUTION variates, which is itself a BETA PRIME DISTRIBUTION variate,

$$\frac{\gamma\left(\frac{n_1}{2}\right)}{\gamma\left(\frac{n_2}{2}\right)} = \beta' \left(\frac{n_1}{2}, \frac{n_2}{2}\right), \quad (5)$$

giving

$$f(F) = \frac{\left(\frac{n_1 F}{n_2}\right)^{n_1/2-1} \left(1 + \frac{n_1 F}{n_2}\right)^{-(n_1+n_2)/2} \frac{n_1}{n_2}}{B\left(\frac{n_1}{2}, \frac{n_2}{2}\right)}. \quad (6)$$

The MEAN is

$$\langle F \rangle = \frac{n_2}{n_2 - 2}, \quad (7)$$

and the MODE is

$$\frac{n_2}{n_2 + 2} \frac{n_1 - 2}{n_1}. \quad (8)$$

see also BETA DISTRIBUTION, BETA PRIME DISTRIBUTION, CHI-SQUARED DISTRIBUTION, GAMMA DISTRIBUTION, NORMAL DISTRIBUTION, STUDENT'S  $t$ -DISTRIBUTION

### Fisher's $z'$ -Transformation

Let  $r$  be the CORRELATION COEFFICIENT. Then defining

$$z' \equiv \tanh^{-1} r \quad (1)$$

$$\zeta \equiv \tanh^{-1} \rho, \quad (2)$$

gives

$$\sigma_{z'} = (N - 3)^{-1/2} \quad (3)$$

$$\text{var}(z') = \frac{1}{n} + \frac{4 - \rho^2}{2n^2} + \dots \quad (4)$$

$$\gamma_1 = \frac{\rho \left| \rho^2 - \frac{9}{16} \right|}{n^{3/2}} \quad (5)$$

$$\gamma_2 = \frac{32 - 3\rho^4}{16N}, \quad (6)$$

where  $n \equiv N - 1$ .

see also CORRELATION COEFFICIENT

### Fitting Subgroup

The unique smallest NORMAL NILPOTENT SUBGROUP of  $H$ , denoted  $F(H)$ . The generalized fitting subgroup is defined by  $F^*(H) = F(H)E(H)$ , where  $E(H)$  is the commuting product of all components of  $H$ , and  $F$  is the fitting subgroup of  $H$ .

### Five Cubes

see CUBE 5-COMPOUND

**Five Disks Problem**

Given five *equal* DISKS placed *symmetrically* about a given center, what is the smallest RADIUS  $r$  for which the RADIUS of the circular AREA covered by the five disks is 1? The answer is  $r = \phi - 1 = 1/\phi = 0.6180340\dots$ , where  $\phi$  is the GOLDEN RATIO, and the centers  $c_i$  of the disks  $i = 1, \dots, 5$  are located at

$$c_i = \left[ \begin{array}{c} \frac{1}{\phi} \cos \left( \frac{2\pi i}{5} \right) \\ \frac{1}{\phi} \sin \left( \frac{2\pi i}{5} \right) \end{array} \right].$$

The GOLDEN RATIO enters here through its connection with the regular PENTAGON. If the requirement that the disks be symmetrically placed is dropped (the general DISK COVERING PROBLEM), then the RADIUS for  $n = 5$  disks can be reduced slightly to 0.609383... (Neville 1915).

see also ARC, DISK COVERING PROBLEM, FLOWER OF LIFE, SEED OF LIFE

**Five Tetrahedra Compound**

see TETRAHEDRON 5-COMPOUND

**Fixed**

When referring to a planar object, "fixed" means that the object is regarded as fixed in the plane so that it may not be picked up and flipped. As a result, MIRROR IMAGES are not necessarily equivalent for fixed objects.

see also FREE, MIRROR IMAGE

**Fixed Element**

see FIXED POINT (MAP)

**Fixed Point**

A point which does not change upon application of a MAP, system of DIFFERENTIAL EQUATIONS, etc.

see also FIXED POINT (DIFFERENTIAL EQUATIONS), FIXED POINT (MAP), FIXED POINT THEOREM

**References**

- Shashkin, Yu. A. *Fixed Points*. Providence, RI: Amer. Math. Soc., 1991.

**Fixed Point (Differential Equations)**

Points of an AUTONOMOUS system of ordinary differential equations at which

$$\begin{cases} \frac{dx_1}{dt} = f_1(x_1, \dots, x_n) = 0 \\ \vdots \\ \frac{dx_n}{dt} = f_n(x_1, \dots, x_n) = 0. \end{cases}$$

If a variable is slightly displaced from a FIXED POINT, it may (1) move back to the fixed point ("asymptotically stable" or "superstable"), (2) move away ("unstable"), or (3) move in a neighborhood of the fixed point but not approach it ("stable" but not "asymptotically stable"). Fixed points are also called CRITICAL POINTS or EQUILIBRIUM POINTS. If a variable starts at a point that is not a CRITICAL POINT, it cannot reach a critical point in a finite amount of time. Also, a trajectory passing through at least one point that is not a CRITICAL POINT cannot cross itself unless it is a CLOSED CURVE, in which case it corresponds to a periodic solution.

A fixed point can be classified into one of several classes using LINEAR STABILITY analysis and the resulting STABILITY MATRIX.

see also ELLIPTIC FIXED POINT (DIFFERENTIAL EQUATIONS), HYPERBOLIC FIXED POINT (DIFFERENTIAL EQUATIONS), STABLE IMPROPER NODE, STABLE NODE, STABLE SPIRAL POINT, STABLE STAR, UNSTABLE IMPROPER NODE, UNSTABLE NODE, UNSTABLE SPIRAL POINT, UNSTABLE STAR

**Fixed Point (Map)**

A point  $x^*$  which is mapped to itself under a MAP  $G$ , so that  $x^* = G(x^*)$ . Such points are sometimes also called INVARIANT POINTS, or FIXED ELEMENTS (Woods 1961). Stable fixed points are called elliptical. Unstable fixed points, corresponding to an intersection of a stable and unstable invariant MANIFOLD, are called HYPERBOLIC (or SADDLE). Points may also be called asymptotically stable (a.k.a. superstable).

see also CRITICAL POINT, INVOLUNTARY

### Flexible Polyhedron

The RIGIDITY THEOREM states that if the faces of a convex POLYHEDRON are made of metal plates and the EDGES are replaced by hinges, the POLYHEDRON would be RIGID. The theorem was stated by Cauchy (1813), although a mistake in this paper went unnoticed for more than 50 years. Concave polyhedra need not be RIGID, and such nonrigid polyhedra are called flexible polyhedra. Connelly (1978) found the first example of a reflexible polyhedron, consisting of 18 triangular faces. A flexible polyhedron with only 14 triangular faces and 9 vertices (shown above), believed to be the simplest possible composed of only triangles, was subsequently found by Steffen (Mackenzie 1998). There also exists a six-vertex eight-face flexible polyhedron (Wunderlich and Schwabe 1986, Cromwell 1997).

Connelly *et al.* (1997) proved that a flexible polyhedron must keep its VOLUME constant (Mackenzie 1998).

### Flexatube

A FLEXAGON-like structure created by connecting the ends of a strip of four squares after folding along 45° diagonals. Using a number of folding movements, it is possible to flip the flexatube inside out so that the faces originally facing inward face outward. Gardner (1961) illustrated one possible solution, and Steinhaus (1983) gives a second.

### Flip Bifurcation

Let  $f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$  be a one-parameter family of  $C^3$  maps satisfying

$$f(0, 0) = 0$$

$$\left[ \frac{\partial f}{\partial x} \right]_{\mu=0, x=0} = -1$$

$$\left[ \frac{\partial^2 f}{\partial x^2} \right]_{\mu=0, x=0} < 0$$

$$\left[ \frac{\partial^3 f}{\partial x^3} \right]_{\mu=0, x=0} < 0.$$

Then there are intervals  $(\mu_1, 0)$ ,  $(0, \mu_2)$ , and  $\epsilon > 0$  such that

1. If  $\mu \in (0, \mu_2)$ , then  $f_\mu(x)$  has one unstable fixed point and one stable orbit of period two for  $x \in (-\epsilon, \epsilon)$ , and
2. If  $\mu \in (\mu_1, 0)$ , then  $f_\mu(x)$  has a single stable fixed point for  $x \in (-\epsilon, \epsilon)$ .

This type of BIFURCATION is known as a flip bifurcation. An example of an equation displaying a flip bifurcation is

$$f(x) = \mu - x - x^2.$$

see also BIFURCATION

#### Floor Function

The function  $[x]$  is the largest INTEGER  $\leq x$ , shown as the dashed curve in the above plot, and also called the GREATEST INTEGER FUNCTION. In many computer languages, the floor function is called the INTEGER PART function and is denoted  $\text{int}(x)$ . The name and symbol for the floor function were coined by K. E. Iverson (Graham *et al.* 1990).

Unfortunately, in many older and current works (e.g., Shanks 1993, Ribenboim 1996), the symbol  $[x]$  is used instead of  $\lfloor x \rfloor$ . Because of the elegant symmetry of the floor function and CEILING FUNCTION symbols  $\lfloor x \rfloor$  and  $\lceil x \rceil$ , and because  $[x]$  is such a useful symbol when interpreted as an IVERSON BRACKET, the use of  $[x]$  to denote the floor function should be deprecated. In this work, the symbol  $\lfloor x \rfloor$  is used to denote the nearest integer NINT function since it naturally falls between the  $\lfloor x \rfloor$  and  $\lceil x \rceil$  symbols.

see also CEILING FUNCTION, FRACTIONAL PART, INT, IVERSON BRACKET, NINT

#### Floquet Analysis

Given a system of periodic ORDINARY DIFFERENTIAL EQUATIONS of the form

$$\frac{d}{dt} \begin{bmatrix} x \\ y \\ v_x \\ v_y \end{bmatrix} = - \begin{bmatrix} 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \\ \Phi_{xx} & \Phi_{xy} & 0 & 0 \\ \Phi_{yx} & \Phi_{yy} & 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ v_x \\ v_y \end{bmatrix}, \quad (1)$$

the solution can be written as a linear combination of functions of the form

$$\begin{bmatrix} x(t) \\ y(t) \\ v_x(t) \\ v_y(t) \end{bmatrix} = \begin{bmatrix} x_0 \\ y_0 \\ v_{x0} \\ v_{y0} \end{bmatrix} e^{\mu t} P_\mu(t), \quad (2)$$

where  $P_\mu(t)$  is a function periodic with the same period  $T$  as the equations themselves. Given an ORDINARY DIFFERENTIAL EQUATION of the form

$$\ddot{x} + g(t)x = 0, \quad (3)$$

where  $g(t)$  is periodic with period  $T$ , the ODE has a pair of independent solutions given by the REAL and IMAGINARY PARTS of

$$x(t) = w(t)e^{i\psi(t)} \quad (4)$$

$$\dot{x} = (\dot{w} + i w \dot{\psi})e^{i\psi} \quad (5)$$

$$\ddot{x} = [\ddot{w} + i \dot{w} \dot{\psi} + i(\dot{w} \dot{\psi} + w \ddot{\psi} + i w \dot{\psi}^2)]e^{i\psi} = [(\ddot{w} - w \dot{\psi}^2) + i(2\dot{w} \dot{\psi} + w \ddot{\psi})]e^{i\psi}. \quad (6)$$

Plugging these into (3) gives

$$\ddot{w} + 2i \dot{w} \dot{\psi} + w(g + i \ddot{\psi} - \dot{\psi}^2) = 0, \quad (7)$$

so the REAL and IMAGINARY PARTS are

$$\ddot{w} + w(g - \dot{\psi}^2) = 0 \quad (8)$$

$$2\dot{w} \dot{\psi} + w \ddot{\psi} = 0. \quad (9)$$

From (9),

$$\begin{aligned} \frac{2\dot{w}}{w} + \frac{\ddot{\psi}}{\dot{\psi}} &= 2 \frac{d}{dt}(\ln w) + \frac{d}{dt}[\ln(\dot{\psi})] \\ &= \frac{d}{dt} \ln(\dot{\psi} w^2) = 0. \end{aligned} \quad (10)$$

Integrating gives

$$\dot{\psi} = \frac{C}{w^2}, \quad (11)$$

where  $C$  is a constant which must equal 1, so  $\psi$  is given by

$$\psi = \int_{t_0}^t \frac{dt}{w^2}. \quad (12)$$

The REAL solution is then

$$x(t) = w(t) \cos[\psi(t)], \quad (13)$$

so

$$\begin{aligned} \dot{x} &= \dot{w} \cos \psi - w \dot{\psi} \sin \psi = \dot{w} \frac{x}{w} - w \dot{\psi} \sin \psi \\ &= \dot{w} \frac{x}{w} - w \frac{1}{w^2} \sin \psi = \dot{w} \frac{x}{w} - \frac{1}{w} \sin \psi \end{aligned} \quad (14)$$

and

$$\begin{aligned} 1 &= \cos^2 \psi + \sin^2 \psi = x^2 w^{-2} + \left[ w \left( \dot{w} \frac{x}{w} - \frac{1}{w} \right) \right]^2 \\ &= x^2 w^{-2} + (\dot{w} x - w)^2 \equiv I(x, \dot{x}, t), \end{aligned} \quad (15)$$

which is an integral of motion. Therefore, although  $w(t)$  is not explicitly known, an integral  $I$  always exists. Plugging (10) into (8) gives

$$\ddot{w} + g(t)w - \frac{1}{w^3} = 0, \quad (16)$$

which, however, is not any easier to solve than (3).

## Flying Conjecture

Also called the TAIT FLYPING CONJECTURE. Given two reduced alternating projections of the same knot, they are equivalent on the SPHERE IFF they are related by a series of FLYPES. It was proved by Menasco and Thistlethwaite (1991). It allows all possible REDUCED alternating projections of a given ALTERNATING KNOT to be drawn.

## Fold Bifurcation

Let  $f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$  be a one-parameter family of  $C^2$  MAP satisfying

$$\begin{aligned} f(0, 0) &= 0 \\ \left[ \frac{\partial f}{\partial x} \right]_{\mu=0, x=0} &= 1 \\ \left[ \frac{\partial^2 f}{\partial x^2} \right]_{\mu=0, x=0} &> 0 \\ \left[ \frac{\partial f}{\partial \mu} \right]_{\mu=0, x=0} &> 0, \end{aligned}$$

then there exist intervals  $(\mu_1, 0)$ ,  $(0, \mu_2)$  and  $\epsilon > 0$  such that

1. If  $\mu \in (\mu_1, 0)$ , then  $f_\mu(x)$  has two fixed points in  $(-\epsilon, \epsilon)$  with the positive one being unstable and the negative one stable, and
2. If  $\mu \in (0, \mu_2)$ , then  $f_\mu(x)$  has no fixed points in  $(-\epsilon, \epsilon)$ .

This type of BIFURCATION is known as a fold bifurcation, sometimes also called a SADDLE-NODE BIFURCATION or TANGENT BIFURCATION. An example of an equation displaying a fold bifurcation is

$$\dot{x} = \mu - x^2$$

(Guckenheimer and Holmes 1997, p. 145).

see also BIFURCATION

## Fold Catastrophe

A CATASTROPHE which can occur for one control factor and one behavior axis.

## Folding

The points accessible from  $c$  by a single fold which leaves  $a_1, \dots, a_n$  fixed are exactly those points interior to or on the boundary of the intersection of the CIRCLES through  $c$  with centers at  $a_i$ , for  $i = 1, \dots, n$ . Given any three points in the plane  $a, b$ , and  $c$ , there is an EQUILATERAL TRIANGLE with VERTICES  $x, y$ , and  $z$  for which  $a, b$ , and  $c$  are the images of  $x, y$ , and  $z$  under a single fold. Given any four points in the plane  $a, b, c$ , and  $d$ , there is some SQUARE with VERTICES  $x, y, z$ , and  $w$  for which  $a, b, c$ , and  $d$  are the images of  $x, y, z$ , and  $w$  under a sequence of at most three folds. Also, any four collinear points are the images of the VERTICES of a suitable SQUARE under at most two folds. Every five (six) points are the images of the VERTICES of suitable regular PENTAGON (HEXAGON) under at most five (six) folds. The least number of folds required for  $n \geq 4$  is not known, but some bounds are. In particular, every set of  $n$  points is the image of a suitable REGULAR  $n$ -gon under at most  $F(n)$  folds, where

$$F(n) \leq \begin{cases} \frac{1}{2}(3n-2) & \text{for } n \text{ even} \\ \frac{1}{2}(3n-3) & \text{for } n \text{ odd.} \end{cases}$$

The first few values are 0, 2, 3, 5, 6, 8, 9, 11, 12, 14, 15, 17, 18, 20, 21, ... (Sloane's A007494).

## Foliation

Let  $M^n$  be an  $n$ -MANIFOLD and let  $F = \{F_\alpha\}$  denote a PARTITION of  $M$  into DISJOINT path-connected SUBSETS. Then  $F$  is called a foliation of  $M$  of codimension  $c$  (with  $0 < c < n$ ) if there EXISTS a COVER of  $M$  by OPEN SETS  $U$ , each equipped with a HOMEOMORPHISM  $h : U \rightarrow \mathbb{R}^n$  or  $h : U \rightarrow \mathbb{R}_+^n$  which throws each nonempty component of  $F_\alpha \cap U$  onto a parallel translation of the standard HYPERPLANE  $\mathbb{R}^{n-c}$  in  $\mathbb{R}^n$ . Each  $F_\alpha$  is then called a LEAF and is not necessarily closed or compact.

**Folium**

The word "folium" means leaf-shaped. The polar equation is

$$r = \cos \theta (4a \sin^2 \theta - b).$$

If  $b \geq 4a$ , it is a single folium. If  $b = 0$ , it is a BIFOLIUM. If  $0 < b < 4a$ , it is a TRIFOLIUM. The simple folium is the PEDAL CURVE of the DELTOID where the PEDAL POINT is one of the CUSPS.

see also BIFOLIUM, FOLIUM OF DESCARTES, KEPLER'S FOLIUM, QUADRIFOLIUM, ROSE, TRIFOLIUM

**References**

MacTutor History of Mathematics Archive. "Folium." <http://www-groups.dcs.st-and.ac.uk/~history/Curves/Folium.html>.

**Folium of Descartes**

A plane curve proposed by Descartes to challenge Fermat's extremum-finding techniques. In parametric form,

$$x = \frac{3at}{1+t^3} \quad (1)$$

$$y = \frac{3at^2}{1+t^3}. \quad (2)$$

The curve has a discontinuity at  $t = -1$ . The left wing is generated as  $t$  runs from  $-1$  to  $0$ , the loop as  $t$  runs from  $0$  to  $\infty$ , and the right wing as  $t$  runs from  $-\infty$  to  $-1$ .

The CURVATURE and TANGENTIAL ANGLE of the folium of Descartes, illustrated above, are

$$\kappa(t) = \frac{2(1+t^3)^4}{3(1+4t^2-4t^3-4t^5+4t^6+t^8)^{3/2}} \quad (3)$$

$$\phi(t) = \frac{1}{2} \left[ \pi + \tan^{-1} \left( \frac{1-2t^3}{t^4-2t} \right) - \tan^{-1} \left( \frac{2t^3-1}{t^4-2t} \right) \right]. \quad (4)$$

Converting the parametric equations to POLAR COORDINATES gives

$$r^2 = \frac{(3at)^2(1+t^2)}{(1+t^3)^2} \quad (5)$$

$$\theta = \tan^{-1} \left( \frac{y}{x} \right) = \tan^{-1} t, \quad (6)$$

so

$$d\theta = \frac{dt}{1+t^2}. \quad (7)$$

The AREA enclosed by the curve is

$$\begin{aligned} A &= \frac{1}{2} \int r^2 d\theta = \frac{1}{2} \int_0^\infty \frac{(3at)^2(1+t^2)}{(1+t^3)^2} \frac{dt}{1+t^2} \\ &= \frac{3}{2} a^2 \int_0^\infty \frac{3t^2 dt}{(1+t^3)^2}. \end{aligned} \quad (8)$$

Now let  $u \equiv 1+t^3$  so  $du = 3t^2 dt$

$$A = \frac{3}{2} a^2 \int_1^\infty \frac{du}{u^2} = \frac{3}{2} a^2 \left[ -\frac{1}{u} \right]_1^\infty = \frac{3}{2} a^2 (-0+1) = \frac{3}{2} a^2. \quad (9)$$

In CARTESIAN COORDINATES,

$$x^3 + y^3 = \frac{(3at)^3(1+t^3)}{(1+t^3)^3} = \frac{(3at)^3}{(1+t^3)^2} = 3axy \quad (10)$$

(MacTutor Archive). The equation of the ASYMPTOTE is

$$y = -a - x. \quad (11)$$

**Fontené Theorems**

1. If the sides of the PEDAL TRIANGLE of a point  $P$  meet the corresponding sides of a TRIANGLE  $\triangle O_1O_2O_3$  at  $X_1$ ,  $X_2$ , and  $X_3$ , respectively, then  $P_1X_1$ ,  $P_2X_2$ ,  $P_3X_3$  meet at a point  $L$  common to the CIRCLES  $O_1O_2O_3$  and  $P_1P_2P_3$ . In other words,  $L$  is one of the intersections of the NINE-POINT CIRCLE of  $A_1A_2A_3$  and the PEDAL CIRCLE of  $P$ .
2. If a point moves on a fixed line through the CIRCUMCENTER, then its PEDAL CIRCLE passes through a fixed point on the NINE-POINT CIRCLE.

3. The PEDAL CIRCLE of a point is tangent to the NINE-POINT CIRCLE IFF the point and its ISOGONAL CONJUGATE lie on a LINE through the ORTHOCENTER. FEUERBACH'S THEOREM is a special case of this theorem.

#### Ford Circle

Pick any two INTEGERS  $h$  and  $k$ , then the CIRCLE of RADIUS  $1/(2k^2)$  centered at  $(h/k, 1/(2k^2))$  is known as a Ford circle. No matter what and how many  $h$ s and  $k$ s are picked, none of the Ford circles intersect (and all are tangent to the  $x$ -AXIS). This can be seen by examining the squared distance between the centers of the circles with  $(h, k)$  and  $(h', k')$ ,

$$d^2 = \left( \frac{h'}{k'} - \frac{h}{k} \right)^2 + \left( \frac{1}{2k'^2} - \frac{1}{2k^2} \right)^2. \quad (1)$$

Let  $s$  be the sum of the radii

$$s = r_1 + r_2 = \frac{1}{2k^2} + \frac{1}{2k'^2}, \quad (2)$$

then

$$d^2 - s^2 = \frac{(h'k - hk')^2 - 1}{k^2 k'^2}. \quad (3)$$

But  $(h'k - k'h)^2 \geq 1$ , so  $d^2 - s^2 \geq 0$  and the distance between circle centers is  $\geq$  the sum of the CIRCLE RADII, with equality (and therefore tangency) IFF  $|h'k - k'h| = 1$ . Ford circles are related to the FAREY SEQUENCE (Conway and Guy 1996).

#### Ford's Theorem

Let  $a$ ,  $b$ , and  $k$  be INTEGERS with  $k \geq 1$ . For  $j = 0, 1, 2$ , let

$$S_j \equiv \sum_{\substack{i=0 \\ i \equiv j \pmod{3}}}^k (-1)^j \binom{k}{i} a^{k-i} b^i.$$

Then

$$2(a^2 + ab + b^2)^{2k} = (S_0 - S_1)^4 + (S_1 - S_2)^4 + (S_2 - S_0)^4.$$

**Fortunate Prime**

Let

$$X_k \equiv 1 + p_k\#,$$

where  $p_k$  is the  $k$ th PRIME and  $p\#$  is the PRIMORIAL, and let  $q_k$  be the NEXT PRIME (i.e., the smallest PRIME greater than  $X_k$ ),

$$q_k = p_{1+\pi(X_k)} = p_{1+\pi(1+p_k\#)},$$

where  $\pi(n)$  is the PRIME COUNTING FUNCTION. Then R. F. Fortune conjectured that  $F_k \equiv q_k - X_k + 1$  is PRIME for all  $k$ . The first values of  $F_k$  are 3, 5, 7, 13, 23, 17, 19, 23, ... (Sloane's A005235), and all known values of  $F_k$  are indeed PRIME (Guy 1994). The indices of these primes are 2, 3, 4, 6, 9, 7, 8, 9, 12, 18, .... In numerical order with duplicates removed, the Fortunate primes are 3, 5, 7, 13, 17, 19, 23, 37, 47, 59, 61, 67, 71, 79, 89, ... (Sloane's A046066).

### Forward Difference

The forward difference is a FINITE DIFFERENCE defined by

$$\Delta f_p \equiv f_{p+1} - f_p. \quad (1)$$

Higher order differences are obtained by repeated operations of the forward difference operator, so

$$\begin{aligned} \Delta^2 f_p &= \Delta_p^2 = \Delta(\Delta_p) = \Delta(f_{p+1} - f_p) \\ &= \Delta_{p+1} - \Delta_p = f_{p+2} - 2f_{p+1} + f_p. \end{aligned} \quad (2)$$

In general,

$$\Delta_p^k \equiv \Delta^k f_p \equiv \sum_{m=0}^k (-1)^m \binom{k}{m} f_{p+k-m}, \quad (3)$$

where  $\binom{k}{m}$  is a BINOMIAL COEFFICIENT.

NEWTON'S FORWARD DIFFERENCE FORMULA expresses  $f_p$  as the sum of the  $n$ th forward differences

$$f_p = f_0 + p\Delta_0 + \frac{1}{2!}p(p+1)\Delta_0^2 + \frac{1}{3!}p(p+1)(p+2)\Delta_0^3 + \dots \quad (4)$$

where  $\Delta_0^n$  is the first  $n$ th difference computed from the difference table.

### Four-Color Theorem

The four-color theorem states that any map in a PLANE can be colored using four-colors in such a way that regions sharing a common boundary (other than a single point) do not share the same color. This problem is sometimes also called GUTHRIE'S PROBLEM after F. Guthrie, who first conjectured the theorem in 1853. The CONJECTURE was then communicated to de Morgan and thence into the general community. In 1878, Cayley wrote the first paper on the conjecture.

Fallacious proofs were given independently by Kempe (1879) and Tait (1880). Kempe's proof was accepted for a decade until Heawood showed an error using a map with 18 faces (although a map with nine faces suffices to show the fallacy). The HEAWOOD CONJECTURE provided a very general result for map coloring, showing that in a GENUS 0 SPACE (i.e., either the SPHERE or PLANE), six colors suffice. This number can easily be reduced to five, but reducing the number of colors all the way to four proved very difficult.

Finally, Appel and Haken (1977) announced a computer-assisted proof that four colors were SUFFICIENT. However, because part of the proof consisted of an exhaustive analysis of many discrete cases by a computer, some mathematicians do not accept it. However, no flaws have yet been found, so the proof appears valid. A potentially independent proof has recently been constructed by N. Robertson, D. P. Sanders, P. D. Seymour, and R. Thomas.

Martin Gardner (1975) played an April Fool's joke by (incorrectly) claiming that the map of 110 regions illustrated below requires five colors and constitutes a counterexample to the four-color theorem.

#### Four Travelers Problem

Let four LINES in a PLANE represent four roads in GENERAL POSITION, and let one traveler  $T_i$  be walking along each road at a constant (but not necessarily equal to any other traveler's) speed. Say that two travelers  $T_i$  and  $T_j$  have "met" if they were simultaneously at the intersection of their two roads. Then if  $T_1$  has met all other three travelers ( $T_2$ ,  $T_3$ , and  $T_4$ ) and  $T_2$ , in addition to meeting  $T_1$ , has met  $T_3$  and  $T_4$ , then  $T_3$  and  $T_4$  have also met!

#### References

#### Four-Vector

A four-element vector

$$a^\mu = \begin{bmatrix} a^0 \\ a^1 \\ a^2 \\ a^3 \end{bmatrix}, \quad (1)$$

which transforms under a LORENTZ TRANSFORMATION like the POSITION FOUR-VECTOR. This means it obeys

$$a'^\mu = \Lambda_\nu^\mu a^\nu \quad (2)$$

$$a_\mu \cdot b_\mu \equiv a_\mu b^\mu \quad (3)$$

$$a_\mu \cdot b^\mu = a'_\mu b'^\mu, \quad (4)$$

where  $\Lambda_\mu^\mu$  is the LORENTZ TENSOR. Multiplication of two four-vectors with the METRIC  $g_{\mu\nu}$  gives products of the form

$$g_{\mu\nu} x^\mu x^\nu = (x^0)^2 - (x^1)^2 - (x^2)^2 - (x^3)^2. \quad (5)$$

In the case of the POSITION FOUR-VECTOR,  $x^0 = ct$  (where  $c$  is the speed of light) and this product is an invariant known as the spacetime interval.

The  $n \times n$  SQUARE MATRIX  $F_n$  with entries given by

$$F_{jk} = e^{2\pi ijk/n} \quad (1)$$

for  $j, k = 1, 2, \dots, n$ , and normalized by  $1/\sqrt{n}$  to make it a UNITARY. The Fourier matrix  $F_2$  is given by

$$F_2 = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & i^2 \end{bmatrix}, \quad (2)$$

and the  $F_4$  matrix by

$$\begin{aligned} F_4 &= \frac{1}{\sqrt{4}} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & i & i^2 & i^3 \\ 1 & i^2 & i^4 & i^6 \\ 1 & i^3 & i^6 & i^9 \end{bmatrix} \\ &= \frac{1}{2} \begin{bmatrix} 1 & 1 & 1 & 1 \\ 1 & i & -1 & -i \\ 1 & -1 & 1 & i \\ 1 & i & -1 & -i \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & i^2 \\ 1 & 1 \\ 1 & i^2 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 1 & 1 \\ 1 & 1 \\ 1 & 1 \end{bmatrix}. \end{aligned} \quad (3)$$

In general,

$$F_{2n} = \begin{bmatrix} I_n & D_n \\ I_n & -D_n \end{bmatrix} \begin{bmatrix} F_n & \\ & F_n \end{bmatrix} \begin{bmatrix} \text{even-odd} \\ \text{shuffle} \end{bmatrix}, \quad (4)$$

with

$$\begin{aligned} \begin{bmatrix} F_n & \\ & F_n \end{bmatrix} &= \begin{bmatrix} I_{n/2} & D_{n/2} \\ I_{n/2} & -D_{n/2} \end{bmatrix} \begin{bmatrix} I_{n/2} & D_{n/2} \\ I_{n/2} & -D_{n/2} \end{bmatrix} \\ &\times \begin{bmatrix} F_{n/2} & & & \\ & F_{n/2} & & \\ & & F_{n/2} & \\ & & & F_{n/2} \end{bmatrix} \begin{bmatrix} \text{even-odd} \\ 0, 2 \pmod{4} \\ \text{even-odd} \\ 1, 3 \pmod{4} \end{bmatrix}, \end{aligned} \quad (5)$$

where  $I_n$  is the  $n \times n$  IDENTITY MATRIX. Note that the factorization (which is the basis of the FAST FOURIER TRANSFORM) has two copies of  $F_2$  in the center factor MATRIX.

### Fourier-Mellin Integral

The inverse of the LAPLACE TRANSFORM

$$F(t) = \mathcal{L}^{-1}[f(s)] = \frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} e^{st} f(s) ds$$

$$f(s) = \mathcal{L}[F(t)] = \int_0^{\infty} F(t) e^{-st} dt.$$

see also BROWICH INTEGRAL, LAPLACE TRANSFORM

**Fourier Series**

Fourier series are expansions of PERIODIC FUNCTIONS  $f(x)$  in terms of an infinite sum of SINES and COSINES

$$f(x) = \sum_{n=0}^{\infty} a_n \cos(nx) + \sum_{n=0}^{\infty} b_n \sin(nx). \quad (1)$$

Fourier series make use of the ORTHOGONALITY relationships of the SINE and COSINE functions, which can be used to calculate the coefficients  $a_n$  and  $b_n$  in the sum. The computation and study of Fourier series is known as HARMONIC ANALYSIS.

To compute a Fourier series, use the integral identities

$$\int_{-\pi}^{\pi} \sin(mx) \sin(nx) dx = \pi \delta_{mn} \quad \text{for } n, m \neq 0 \quad (2)$$

$$\int_{-\pi}^{\pi} \cos(mx) \cos(nx) dx = \pi \delta_{mn} \quad \text{for } n, m \neq 0 \quad (3)$$

$$\int_{-\pi}^{\pi} \sin(mx) \cos(nx) dx = 0 \quad (4)$$

$$\int_{-\pi}^{\pi} \sin(mx) dx = 0 \quad (5)$$

$$\int_{-\pi}^{\pi} \cos(mx) dx = 0, \quad (6)$$

where  $\delta_{mn}$  is the KRONECKER DELTA. Now, expand your function  $f(x)$  as an infinite series of the form

$$\begin{aligned} f(x) &= \sum_{n=0}^{\infty} a'_n \cos(nx) + \sum_{n=0}^{\infty} b_n \sin(nx) \\ &= \frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx), \quad (7) \end{aligned}$$

where we have relabeled the  $a_0 = 2a'_0$  term for future convenience but left  $a_n = a'_n$ . Assume the function is periodic in the interval  $[-\pi, \pi]$ . Now use the orthogonality conditions to obtain

$$\begin{aligned} \int_{-\pi}^{\pi} f(x) dx &= \int_{-\pi}^{\pi} \left[ \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0 \right] dx \\ &= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) + b_n \sin(nx)] dx + \frac{1}{2}a_0 \int_{-\pi}^{\pi} dx \\ &= \sum_{n=1}^{\infty} (0 + 0) + \pi a_0 = \pi a_0 \quad (8) \end{aligned}$$

and

$$\begin{aligned} \int_{-\pi}^{\pi} f(x) \sin(mx) dx &= \int_{-\pi}^{\pi} \left[ \sum_{n=1}^{\infty} a_n \cos(nx) + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0 \right] \\ &\quad \times \sin(mx) dx \\ &= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) \sin(mx) + b_n \sin(nx) \sin(mx)] dx \\ &\quad + \frac{1}{2}a_0 \int_{-\pi}^{\pi} \sin(mx) dx \\ &= \sum_{n=1}^{\infty} (0 + b_n \pi \delta_{mn}) + 0 = \pi b_n, \quad (9) \end{aligned}$$

so

$$\begin{aligned} \int_{-\pi}^{\pi} f(x) \cos(mx) dx &= \int_{-\pi}^{\pi} \left[ \sum_{n=1}^{\infty} a_n \cos(nx) \right. \\ &\quad \left. + \sum_{n=1}^{\infty} b_n \sin(nx) + \frac{1}{2}a_0 \right] \cos(mx) dx \\ &= \sum_{n=1}^{\infty} \int_{-\pi}^{\pi} [a_n \cos(nx) \cos(mx) \\ &\quad + b_n \sin(nx) \cos(mx)] dx + \frac{1}{2}a_0 \int_{-\pi}^{\pi} \cos(mx) dx \\ &= \sum_{n=1}^{\infty} (a_n \pi \delta_{mn} + 0) + 0 = \pi a_n. \quad (10) \end{aligned}$$

Plugging back into the original series then gives

$$a_0 = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) dx \quad (11)$$

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \cos(nx) dx \quad (12)$$

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx) dx \quad (13)$$

for  $n = 1, 2, 3, \dots$ . The series expansion converges to the function  $\bar{f}$  (equal to the original function at points of continuity or to the average of the two limits at points of discontinuity)

$$\bar{f} \equiv \begin{cases} \frac{1}{2} [\lim_{x \rightarrow x_0^-} f(x) + \lim_{x \rightarrow x_0^+} f(x)] \\ \text{for } -\pi < x_0 < \pi \\ \frac{1}{2} [\lim_{x \rightarrow -\pi^+} f(x) + \lim_{x \rightarrow \pi^-} f(x)] \\ \text{for } x_0 = -\pi, \pi \end{cases} \quad (14)$$

if the function satisfies the DIRICHLET CONDITIONS.

Near points of discontinuity, a “ringing” known as the GIBBS PHENOMENON, illustrated below, occurs. For a function  $f(x)$  periodic on an interval  $[-L, L]$ , use a change of variables to transform the interval of integration to  $[-1, 1]$ . Let

$$x \equiv \frac{\pi x'}{L} \quad (15)$$

$$dx = \frac{\pi dx'}{L}. \quad (16)$$

Solving for  $x'$ ,  $x' = Lx/\pi$ . Plugging this in gives

$$f(x') = \frac{1}{2}a_0 + \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x'}{L}\right) + \sum_{n=1}^{\infty} b_n \sin\left(\frac{n\pi x'}{L}\right) \quad (17)$$

$$\begin{cases} a_0 = \frac{1}{L} \int_{-L}^L f(x') dx' \\ a_n = \frac{1}{L} \int_{-L}^L f(x') \cos\left(\frac{n\pi x'}{L}\right) dx' \\ b_n = \frac{1}{L} \int_{-L}^L f(x') \sin\left(\frac{n\pi x'}{L}\right) dx' \end{cases} \quad (18)$$

If a function is EVEN so that  $f(x) = f(-x)$ , then  $f(x) \sin(nx)$  is ODD. (This follows since  $\sin(nx)$  is ODD and an EVEN FUNCTION times an ODD FUNCTION is an ODD FUNCTION.) Therefore,  $b_n = 0$  for all  $n$ . Similarly, if a function is ODD so that  $f(x) = -f(-x)$ , then  $f(x) \cos(nx)$  is ODD. (This follows since  $\cos(nx)$  is EVEN and an ODD FUNCTION times an EVEN FUNCTION is an ODD FUNCTION.) Therefore,  $a_n = 0$  for all  $n$ .

Because the SINES and COSINES form a COMPLETE ORTHOGONAL BASIS, the SUPERPOSITION PRINCIPLE holds, and the Fourier series of a linear combination of two functions is the same as the linear combination of the corresponding two series. The COEFFICIENTS for Fourier series expansions for a few common functions are given in Beyer (1987, pp. 411–412) and Byerly (1959, p. 51).

The notion of a Fourier series can also be extended to COMPLEX COEFFICIENTS. Consider a real-valued function  $f(x)$ . Write

$$f(x) = \sum_{n=-\infty}^{\infty} A_n e^{inx}. \quad (19)$$

Now examine

$$\begin{aligned} \int_{-\pi}^{\pi} f(x) e^{-imx} dx &= \int_{-\pi}^{\pi} \left( \sum_{n=-\infty}^{\infty} A_n e^{inx} \right) e^{-imx} dx \\ &= \sum_{n=-\infty}^{\infty} A_n \int_{-\pi}^{\pi} e^{i(n-m)x} dx \\ &= \sum_{n=-\infty}^{\infty} A_n \int_{-\pi}^{\pi} \{\cos[(n-m)x] + i \sin[(n-m)x]\} dx \\ &= \sum_{m=-\infty}^{\infty} A_n 2\pi \delta_{mn} = 2\pi A_m, \quad (20) \end{aligned}$$

so

$$A_n = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) e^{-inx} dx. \quad (21)$$

The COEFFICIENTS can be expressed in terms of those in the FOURIER SERIES

$$\begin{aligned} A_n &= \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) [\cos(nx) - i \sin(nx)] dx \\ &= \begin{cases} \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) [\cos(nx) + i \sin(nx)] dx & n < 0 \\ \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) dx & n = 0 \\ \frac{1}{2\pi} \int_{-\pi}^{\pi} f(x) [\cos(nx) - i \sin(nx)] dx & n > 0 \end{cases} \\ &= \begin{cases} \frac{1}{2}(a_n + ib_n) & n < 0 \\ \frac{1}{2}a_0 & n = 0 \\ \frac{1}{2}(a_n - ib_n) & n > 0. \end{cases} \quad (22) \end{aligned}$$

For a function periodic in  $[-L, L]$ , these become

$$f(x) = \sum_{n=-\infty}^{\infty} A_n e^{i(2\pi nx/L)} \quad (23)$$

$$A_n = \frac{1}{L} \int_{-L/2}^{L/2} f(x) e^{-i(2\pi nx/L)} dx. \quad (24)$$

These equations are the basis for the extremely important FOURIER TRANSFORM, which is obtained by transforming  $A_n$  from a discrete variable to a continuous one as the length  $L \rightarrow \infty$ .

### Fourier Series—Power Series

For  $f(x) = x^k$  on the INTERVAL  $[-L, L]$  and periodic with period  $2L$ , the FOURIER SERIES is given by

$$\begin{aligned} a_n &= \frac{1}{L} \int_{-L}^L x^k \cos\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{2L^k}{1+k} {}_1F_2\left(\frac{1}{2}, \frac{1}{2} + \frac{1}{2}k; \frac{1}{2}(3+k); -\frac{1}{4}\pi^2 n^2\right) \\ b_n &= \frac{1}{L} \int_{-L}^L x^k \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{2n\pi L^k}{2+k} {}_1F_2\left(\frac{3}{2}, \frac{1}{2} + \frac{1}{2}k; \frac{3}{2} + \frac{1}{2}k; -\frac{1}{4}\pi^2 n^2\right), \end{aligned}$$

where  ${}_1F_2(a; b, c; x)$  is a generalized HYPERGEOMETRIC FUNCTION.

### Fourier Series—Right Triangle

Consider a string of length  $2L$  plucked at the right end, then

$$\begin{aligned} a_0 &= \frac{1}{L} \int_0^{2L} \frac{x}{2L} dx = \frac{1}{2L^2} \left[ \frac{1}{2} x^2 \right]_0^{2L} = \frac{1}{4L^2} (2L)^2 = 1 \\ a_n &= \frac{1}{L} \int_0^{2L} \frac{x}{2L} \cos\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{[2n\pi \cos(n\pi) - \sin(n\pi)] \sin(n\pi)}{n^2 \pi^2} = 0 \end{aligned}$$

$$\begin{aligned} b_n &= \frac{1}{L} \int_0^{2L} \frac{x}{2L} \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{-2n\pi \cos(2n\pi) + \sin(2n\pi)}{2n^2 \pi^2} = -\frac{1}{n\pi}. \end{aligned}$$

The Fourier series is therefore

$$f(x) = \frac{1}{2} - \frac{1}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin\left(\frac{n\pi x}{L}\right).$$

see also FOURIER SERIES

### Fourier Series—Square Wave

Consider a square wave of length  $2L$ . Since the function is ODD,  $a_0 = a_n = 0$ , and

$$\begin{aligned} b_n &= \frac{2}{L} \int_0^L \sin\left(\frac{n\pi x}{L}\right) dx \\ &= \frac{4}{n\pi} \sin^2\left(\frac{1}{2}n\pi\right) = \frac{4}{n\pi} \begin{cases} 0 & n \text{ even} \\ 1 & n \text{ odd} \end{cases} \end{aligned}$$

The Fourier series is therefore

$$f(x) = \frac{4}{\pi} \sum_{n=1,3,5,\dots}^{\infty} \frac{1}{n} \sin\left(\frac{n\pi x}{L}\right).$$

see also FOURIER SERIES, SQUARE WAVE

### Fourier Series—Triangle

Let a string of length  $2L$  have a  $y$ -displacement of unity when it is pinned an  $x$ -distance which is  $(1/m)$ th of the way along the string. The displacement as a function of  $x$  is then

$$f_m(x) = \begin{cases} \frac{mx}{2L} & 0 \leq x \leq \frac{2L}{m} \\ \frac{1-m}{1-m} \left( \frac{x}{2L} - 1 \right) & \frac{2L}{m} \leq x \leq 2L. \end{cases}$$

The COEFFICIENTS are therefore

$$\begin{aligned} a_0 &= \frac{1}{L} \left[ \int_0^{2L/m} \frac{nx}{2L} dx + \int_{2L/m}^{2L} \frac{n}{1-n} \left( \frac{x}{2L} - 1 \right) dx \right] \\ &= 1 \\ a_n &= \frac{m \left[ 1 - m - \cos(2\pi n) + m \cos\left(\frac{2n\pi}{m}\right) \right]}{2(m-1)n^2\pi^2} \\ &= \frac{m^2 \left[ \cos\left(\frac{2n\pi}{m}\right) - 1 \right]}{2(m-1)n^2\pi^2} \\ b_n &= \frac{m \left[ m \sin\left(\frac{2n\pi}{m}\right) - \sin(2\pi n) \right]}{2(m-1)n^2\pi^2} \\ &= \frac{m^2 \sin\left(\frac{2n\pi}{m}\right)}{2(m-1)n^2\pi^2}. \end{aligned}$$

The Fourier series is therefore

$$\begin{aligned} f_m(x) &= \frac{1}{2} + \frac{m^2}{2(m-1)\pi^2} \\ &\times \sum_{n=1}^{\infty} \left\{ \frac{1}{n^2} \left[ \cos\left(\frac{2n\pi}{m}\right) - 1 \right] \cos\left(\frac{n\pi x}{L}\right) \right. \\ &\quad \left. + \frac{\sin\left(\frac{2n\pi}{m}\right)}{n^2} \sin\left(\frac{n\pi x}{L}\right) \right\}. \end{aligned}$$

If  $m = 2$ , then  $a_n$  and  $b_n$  simplify to

$$\begin{aligned} a_n &= -\frac{4}{n^2\pi^2} \sin^2\left(\frac{1}{2}n\pi\right) = -\frac{4}{n^2\pi^2} \begin{cases} 0 & n = 0, 2, \dots \\ 1 & n = 1, 3, \dots \end{cases} \\ b_n &= 0, \end{aligned}$$

giving

$$f_2(x) = \frac{1}{2} - \frac{4}{\pi^2} \sum_{n=1,3,5,\dots}^{\infty} \frac{1}{n^2} \cos\left(\frac{n\pi x}{L}\right).$$

see also FOURIER SERIES

## Fourier Series—Triangle Wave

Consider a triangle wave of length  $2L$ . Since the function is ODD,  $a_0 = a_n = 0$ , and

$$\begin{aligned} b_n &= \frac{2}{L} \left\{ \int_0^{L/2} \frac{x}{L/2} \sin\left(\frac{n\pi x}{L}\right) dx \right. \\ &\quad \left. + \int_{L/2}^L \left[ 1 - \frac{2}{L}(x - \frac{1}{2}L) \right] \sin\left(\frac{n\pi x}{L}\right) dx \right\} \\ &= \frac{32}{\pi^2 n^2} \cos\left(\frac{1}{4}n\pi\right) \sin^3\left(\frac{1}{4}n\pi\right) \\ &= \frac{32}{\pi^2 n^2} \begin{cases} 0 & n = 0, 4, \dots \\ \frac{1}{4} & n = 1, 5, \dots \\ 0 & n = 2, 6, \dots \\ -\frac{1}{4} & n = 3, 7, \dots \end{cases} \\ &= \frac{8}{\pi^2 n^2} \begin{cases} (-1)^{(n-1)/2} & \text{for } n \text{ odd} \\ 0 & \text{for } n \text{ even.} \end{cases} \end{aligned}$$

The Fourier series is therefore

$$f(x) = \frac{8}{\pi^2} \sum_{n=1,3,5,\dots}^{\infty} \frac{(-1)^{(n-1)/2}}{n^2} \sin\left(\frac{n\pi x}{L}\right).$$

see also FOURIER SERIES

## Fourier Sine Series

If  $f(x)$  is an ODD FUNCTION, then  $a_n = 0$  and the FOURIER SERIES collapses to

$$f(x) = \sum_{n=1}^{\infty} b_n \sin(nx), \quad (1)$$

where

$$b_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin(nx) dx = \frac{2}{\pi} \int_0^{\pi} f(x) \sin(nx) dx \quad (2)$$

for  $n = 1, 2, 3, \dots$ . The last EQUALITY is true because

$$\begin{aligned} f(x) \sin(nx) &= [-f(-x)][-\sin(-nx)] \\ &= f(-x) \sin(-nx). \end{aligned} \quad (3)$$

Letting the range go to  $L$ ,

$$b_n = \frac{2}{L} \int_0^L f(x) \sin\left(\frac{n\pi x}{L}\right) dx. \quad (4)$$

see also FOURIER COSINE SERIES, FOURIER SERIES, FOURIER SINE TRANSFORM

## Fourier Sine Transform

The Fourier sine transform is the IMAGINARY PART of the full complex FOURIER TRANSFORM,

$$\mathcal{F} \sin[f(x)] = \Im[\mathcal{F}[f(x)]].$$

## Fourier-Stieltjes Transform

Let  $f(x)$  be a positive definite, measurable function on the INTERVAL  $(-\infty, \infty)$ . Then there exists a monotone increasing, real-valued bounded function  $\alpha(t)$  such that

$$f(x) = \int_{-\infty}^{\infty} e^{itx} d\alpha(t)$$

for "ALMOST ALL"  $x$ . If  $\alpha(t)$  is nondecreasing and bounded and  $f(x)$  is defined as above, then  $f(x)$  is called the Fourier-Stieltjes transform of  $\alpha(t)$ , and is both continuous and positive definite.

see also FOURIER TRANSFORM, LAPLACE TRANSFORM

Iyanaga, S. and Kawada, Y. (Eds.). *Encyclopedic Dictionary of Mathematics*. Cambridge, MA: MIT Press, p. 618, 1980.

**Fourier Transform**

The Fourier transform is a generalization of the COMPLEX FOURIER SERIES in the limit as  $L \rightarrow \infty$ . Replace the discrete  $A_n$  with the continuous  $F(k) dk$  while letting  $n/L \rightarrow k$ . Then change the sum to an INTEGRAL, and the equations become

$$f(x) = \int_{-\infty}^{\infty} F(k) e^{2\pi i k x} dk \quad (1)$$

$$F(k) = \int_{-\infty}^{\infty} f(x) e^{-2\pi i k x} dx. \quad (2)$$

Here,

$$F(k) = \mathcal{F}[f(x)] = \int_{-\infty}^{\infty} f(x) e^{-2\pi i k x} dx \quad (3)$$

is called the *forward* ( $-i$ ) Fourier transform, and

$$f(x) = \mathcal{F}^{-1}[F(k)] = \int_{-\infty}^{\infty} F(k) e^{2\pi i k x} dk \quad (4)$$

is called the *inverse* ( $+i$ ) Fourier transform. Some authors (especially physicists) prefer to write the transform in terms of angular frequency  $\omega \equiv 2\pi\nu$  instead of the oscillation frequency  $\nu$ . However, this destroys the symmetry, resulting in the transform pair

$$H(\nu) = \mathcal{F}[h(t)] = \int_{-\infty}^{\infty} h(t) e^{-i\omega t} dt \quad (5)$$

$$h(t) = \mathcal{F}^{-1}[H(\nu)] = \frac{1}{2\pi} \int_{-\infty}^{\infty} H(\nu) e^{i\omega t} d\omega. \quad (6)$$

In general, the Fourier transform pair may be defined using two arbitrary constants  $A$  and  $B$  as

$$F(\omega) = A \int_{-\infty}^{\infty} f(t) e^{B i \omega t} dt \quad (7)$$

$$f(t) = \frac{B}{2\pi A} \int_{-\infty}^{\infty} F(\omega) e^{-B i \omega t} d\omega. \quad (8)$$

The *Mathematica*<sup>®</sup> program (Wolfram Research, Champaign, IL) calls  $A$  the `$FourierOverallConstant` and  $B$  the `$FourierFrequencyConstant`, and defines  $A = B = 1$  by default. Morse and Feshbach (1953) use  $B = 1$  and  $A = 1/\sqrt{2\pi}$ . In this work, following Bracewell (1965, pp. 6–7),  $A = 1$  and  $B = -2\pi$  unless otherwise stated.

Since any function can be split up into EVEN and ODD portions  $E(x)$  and  $O(x)$ ,

$$f(x) = \frac{1}{2}[f(x) + f(-x)] + \frac{1}{2}[f(x) - f(-x)] = E(x) + O(x), \quad (9)$$

a Fourier transform can always be expressed in terms of the FOURIER COSINE TRANSFORM and FOURIER SINE TRANSFORM as

$$\mathcal{F}[f(x)] = \int_{-\infty}^{\infty} E(x) \cos(2\pi k x) dx - i \int_{-\infty}^{\infty} O(x) \sin(2\pi k x) dx. \quad (10)$$

A function  $f(x)$  has a forward and inverse Fourier transform such that

$$f(x) = \begin{cases} \int_{-\infty}^{\infty} e^{2\pi i k x} \left[ \int_{-\infty}^{\infty} f(x) e^{-2\pi i k x} dx \right] dk & \text{for } f(x) \text{ continuous at } x \\ \frac{1}{2}[f(x_+) + f(x_-)] & \text{for } f(x) \text{ discontinuous at } x, \end{cases} \quad (11)$$

provided that

1.  $\int_{-\infty}^{\infty} |f(x)| dx$  exists.
2. Any discontinuities are finite.
3. The function has bounded variation. A SUFFICIENT weaker condition is fulfillment of the LIPSCHITZ CONDITION.

The smoother a function (i.e., the larger the number of continuous DERIVATIVES), the more compact its Fourier transform.

The Fourier transform is linear, since if  $f(x)$  and  $g(x)$  have FOURIER TRANSFORMS  $F(k)$  and  $G(k)$ , then

$$\begin{aligned} \int [af(x) + bg(x)] e^{-2\pi i k x} dx \\ = a \int_{-\infty}^{\infty} f(x) e^{-2\pi i k x} dx + b \int_{-\infty}^{\infty} g(x) e^{-2\pi i k x} dx \\ = F(k) + G(k). \end{aligned} \quad (12)$$

Therefore,

$$\mathcal{F}[af(x) + bg(x)] = a\mathcal{F}[f(x)] + b\mathcal{F}[g(x)] = aF(k) + bG(k). \quad (13)$$

The Fourier transform is also symmetric since  $F(k) = \mathcal{F}[f(x)]$  implies  $F(-k) = \mathcal{F}[f(x)]$ .

Let  $f * g$  denote the CONVOLUTION, then the transforms of convolutions of functions have particularly nice transforms,

$$\mathcal{F}[f * g] = \mathcal{F}[f]\mathcal{F}[g] \quad (14)$$

$$\mathcal{F}[fg] = \mathcal{F}[f] * \mathcal{F}[g] \quad (15)$$

$$\mathcal{F}[\mathcal{F}(f) + \mathcal{F}(g)] = f * g \quad (16)$$

$$\mathcal{F}[\mathcal{F}(f) * \mathcal{F}(g)] = fg. \quad (17)$$

The first of these is derived as follows:

$$\begin{aligned}
 \mathcal{F}[f * g] &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-2\pi i k x} f(x') g(x - x') dx' dx \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} [e^{-2\pi i k x'} f(x') dx'] \\
 &\quad \times [e^{-2\pi i k (x - x')} g(x - x') dx] \\
 &= \left[ \int_{-\infty}^{\infty} e^{-2\pi i k x'} f(x') dx' \right] \\
 &\quad \times \left[ \int_{-\infty}^{\infty} e^{-2\pi i k x''} g(x'') dx'' \right] \\
 &= \mathcal{F}[f] \mathcal{F}[g],
 \end{aligned} \tag{18}$$

where  $x'' = x - x'$ .

There is also a somewhat surprising and extremely important relationship between the AUTOCORRELATION and the Fourier transform known as the WIENER-KHINTCHINE THEOREM. Let  $\mathcal{F}[f(x)] = F(k)$ , and  $F^*$  denote the COMPLEX CONJUGATE of  $F$ , then the FOURIER TRANSFORM of the ABSOLUTE SQUARE of  $F(k)$  is given by

$$\mathcal{F}[|F(k)|^2] = \int_{-\infty}^{\infty} f^*(\tau) f(\tau + x) d\tau. \tag{19}$$

The Fourier transform of a DERIVATIVE  $f'(x)$  of a function  $f(x)$  is simply related to the transform of the function  $f(x)$  itself. Consider

$$\mathcal{F}[f'(x)] = \int_{-\infty}^{\infty} f'(x) e^{-2\pi i k x} dx. \tag{20}$$

Now use INTEGRATION BY PARTS

$$\int v du = [uv] - \int u dv \tag{21}$$

with

$$du = f'(x) dx \quad v = e^{-2\pi i k x} \tag{22}$$

$$u = f(x) \quad dv = -2\pi i k e^{-2\pi i k x} dx, \tag{23}$$

then

$$\begin{aligned}
 \mathcal{F}[f'(x)] &= [f(x) e^{-2\pi i k x}]_{-\infty}^{\infty} - \int_{-\infty}^{\infty} f(x) (-2\pi i k e^{-2\pi i k x}) dx.
 \end{aligned} \tag{24}$$

The first term consists of an oscillating function times  $f(x)$ . But if the function is bounded so that

$$\lim_{x \rightarrow \pm\infty} f(x) = 0 \tag{25}$$

(as any physically significant signal must be), then the term vanishes, leaving

$$\mathcal{F}[f'(x)] = 2\pi i k \int_{-\infty}^{\infty} f(x) e^{-2\pi i k x} dx = 2\pi i k \mathcal{F}[f(x)]. \tag{26}$$

This process can be iterated for the  $n$ th DERIVATIVE to yield

$$\mathcal{F}[f^{(n)}(x)] = (2\pi i k)^n \mathcal{F}[f(x)]. \tag{27}$$

The important MODULATION THEOREM of Fourier transforms allows  $\mathcal{F}[\cos(2\pi k_0 x) f(x)]$  to be expressed in terms of  $\mathcal{F}[f(x)] = F(k)$  as follows,

$$\begin{aligned}
 \mathcal{F}[\cos(2\pi k_0 x) f(x)] &\equiv \int_{-\infty}^{\infty} f(x) \cos(2\pi k_0 x) e^{-2\pi i k x} dx \\
 &= \frac{1}{2} \int_{-\infty}^{\infty} f(x) e^{2\pi i k_0 x} e^{-2\pi i k x} dx \\
 &\quad + \frac{1}{2} \int_{-\infty}^{\infty} f(x) e^{-2\pi i k_0 x} e^{-2\pi i k x} dx \\
 &= \frac{1}{2} \int_{-\infty}^{\infty} f(x) e^{-2\pi i (k - k_0) x} dx \\
 &\quad + \frac{1}{2} \int_{-\infty}^{\infty} f(x) e^{-2\pi i (k + k_0) x} dx \\
 &= \frac{1}{2} [F(k - k_0) + F(k + k_0)].
 \end{aligned} \tag{28}$$

Since the DERIVATIVE of the FOURIER TRANSFORM is given by

$$F'(k) \equiv \frac{d}{dk} \mathcal{F}[f(x)] = \int_{-\infty}^{\infty} (-2\pi i x) f(x) e^{-2\pi i k x} dx, \tag{29}$$

it follows that

$$F'(0) = -2\pi i \int_{-\infty}^{\infty} x f(x) dx. \tag{30}$$

Iterating gives the general FORMULA

$$\mu_n \equiv \int_{-\infty}^{\infty} x^n f(x) dx = \frac{F^{(n)}(0)}{(-2\pi i)^n}. \tag{31}$$

The VARIANCE of a FOURIER TRANSFORM is

$$\sigma_f^2 = \langle (xf - \langle xf \rangle)^2 \rangle, \tag{32}$$

and it is true that

$$\sigma_{f+g} = \sigma_f + \sigma_g. \tag{33}$$

If  $f(x)$  has the FOURIER TRANSFORM  $F(k)$ , then the Fourier transform has the shift property

$$\begin{aligned}
 &\int_{-\infty}^{\infty} f(x - x_0) e^{-2\pi i k x} dx \\
 &= \int_{-\infty}^{\infty} f(x - x_0) e^{-2\pi i (x - x_0) k} e^{-2\pi i (k x_0)} d(x - x_0) \\
 &= e^{-2\pi i k x_0} F(k),
 \end{aligned} \tag{34}$$

so  $f(x - x_0)$  has the FOURIER TRANSFORM

$$\mathcal{F}[f(x - x_0)] = e^{-2\pi i k x_0} F(k). \quad (35)$$

If  $f(x)$  has a FOURIER TRANSFORM  $F(k)$ , then the Fourier transform obeys a similarity theorem.

$$\begin{aligned} \int_{-\infty}^{\infty} f(ax) e^{-2\pi i k x} dx \\ = \frac{1}{|a|} \int_{-\infty}^{\infty} f(ax) e^{-2\pi i (ax)(k/a)} d(ax) \\ = \frac{1}{|a|} F\left(\frac{k}{a}\right), \end{aligned} \quad (36)$$

so  $f(ax)$  has the FOURIER TRANSFORM  $|a|^{-1} F\left(\frac{k}{a}\right)$ .

The “equivalent width” of a Fourier transform is

$$w_e \equiv \frac{\int_{-\infty}^{\infty} f(x) dx}{f(0)} = \frac{F(0)}{\int_{-\infty}^{\infty} F(k) dk}. \quad (37)$$

The “autocorrelation width” is

$$w_a \equiv \frac{\int_{-\infty}^{\infty} f \star f^* dx}{[f \star f^*]_0} = \frac{\int_{-\infty}^{\infty} f dx \int_{-\infty}^{\infty} f^* dx}{\int_{-\infty}^{\infty} f f^* dx}, \quad (38)$$

where  $f \star g$  denotes the CROSS-CORRELATION of  $f$  and  $g$ .

Any operation on  $f(x)$  which leaves its AREA unchanged leaves  $F(0)$  unchanged, since

$$\int_{-\infty}^{\infty} f(x) dx = \mathcal{F}[f(0)] = F(0). \quad (39)$$

In 2-D, the Fourier transform becomes

$$F(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(k_x, k_y) e^{-2\pi i (k_x x + k_y y)} dk_x dk_y \quad (40)$$

$$f(k_x, k_y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F(x, y) e^{2\pi i (k_x x + k_y y)} dx dy. \quad (41)$$

Similarly, the  $n$ -D Fourier transform can be defined for  $\mathbf{k}, \mathbf{x} \in \mathbb{R}^n$  by

$$F(\mathbf{x}) = \underbrace{\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty}}_n f(\mathbf{k}) e^{-2\pi i \mathbf{k} \cdot \mathbf{x}} d^n \mathbf{k} \quad (42)$$

$$f(\mathbf{k}) = \underbrace{\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty}}_n F(\mathbf{x}) e^{2\pi i \mathbf{k} \cdot \mathbf{x}} d^n \mathbf{x}. \quad (43)$$

#### Fourier Transform—1

The FOURIER TRANSFORM of the CONSTANT FUNCTION  $f(x) = 1$  is given by

$$\mathcal{F}[1] = \int_{-\infty}^{\infty} e^{-2\pi i k x} dx = \delta(k),$$

according to the definition of the DELTA FUNCTION.

see also DELTA FUNCTION

**Fourier Transform— $1/x$** 

The FOURIER TRANSFORM of the function  $1/x$  is given by

$$\begin{aligned}\mathcal{F}\left(-\frac{1}{\pi x}\right) &= -\frac{1}{\pi} \int_{-\infty}^{\infty} \frac{e^{-2\pi i k x}}{x} dx \\ &= PV \int_{-\infty}^{\infty} \frac{\cos(2\pi k x) - i \sin(2\pi k x)}{x} dx \\ &= \begin{cases} -\frac{2i}{\pi} \int_0^{\infty} \frac{\sin(2\pi k x)}{x} dx & \text{for } k < 0 \\ \frac{2i}{\pi} \int_0^{\infty} \frac{\sin(2\pi k x)}{x} dx & \text{for } k > 0 \end{cases} \\ &= \begin{cases} -i & \text{for } k < 0 \\ i & \text{for } k > 0, \end{cases} \end{aligned} \quad (1)$$

which can also be written as the single equation

$$\mathcal{F}\left(-\frac{1}{\pi x}\right) = i[1 - 2H(-k)], \quad (2)$$

where  $H(x)$  is the HEAVISIDE STEP FUNCTION. The integrals follow from the identity

$$\begin{aligned}\int_0^{\infty} \frac{\sin(2\pi k x)}{x} dx &= \int_0^{\infty} \frac{\sin(2\pi k x)}{2\pi k x} d(2\pi k x) \\ &= \int_0^{\infty} \operatorname{sinc} z dz = \frac{1}{2}\pi. \end{aligned} \quad (3)$$

**Fourier Transform—Cosine**

$$\begin{aligned}\mathcal{F}[\cos(2\pi k_0 x)] &= \int_{-\infty}^{\infty} e^{-2\pi i k x} \left( \frac{e^{2\pi i k_0 x} + e^{-2\pi i k_0 x}}{2} \right) dx \\ &= \frac{1}{2} \int_{-\infty}^{\infty} [e^{-2\pi i(k-k_0)x} + e^{-2\pi i(k+k_0)x}] dx \\ &= \frac{1}{2} [\delta(k-k_0) + \delta(k+k_0)],\end{aligned}$$

where  $\delta(x)$  is the DELTA FUNCTION.

see also COSINE, FOURIER TRANSFORM—SINE

**Fourier Transform—Delta Function**

The FOURIER TRANSFORM of the DELTA FUNCTION is given by

$$\mathcal{F}[\delta(x-x_0)] = \int_{-\infty}^{\infty} \delta(x-x_0) e^{-2\pi i k x} dx = e^{-2\pi i k x_0}.$$

see also DELTA FUNCTION

**Fourier Transform—Exponential Function**

The FOURIER TRANSFORM of  $e^{-k_0|x|}$  is given by

$$\begin{aligned}\mathcal{F}[e^{-k_0|x|}] &= \int_{-\infty}^{\infty} e^{-k_0|x|} e^{-2\pi i k x} dx \\ &= \int_{-\infty}^0 e^{-2\pi i k x} e^{2\pi k_0 x} dx + \int_0^{\infty} e^{-2\pi i k x} e^{-2\pi k_0 x} dx \\ &= \int_{-\infty}^0 [\cos(2\pi k x) - i \sin(2\pi k x)] e^{2\pi k_0 x} dx \\ &\quad + \int_0^{\infty} [\cos(2\pi k x) - i \sin(2\pi k x)] e^{-2\pi k_0 x} dx. \end{aligned} \quad (1)$$

Now let  $u \equiv -x$  so  $du = -dx$ , then

$$\begin{aligned}\mathcal{F}[e^{-k_0|x|}] &= \int_0^{\infty} [\cos(2\pi k u) + i \sin(2\pi k u)] e^{-2\pi k_0 u} du \\ &\quad + \int_0^{\infty} [\cos(2\pi k u) - i \sin(2\pi k u)] e^{-2\pi k_0 u} du \\ &= 2 \int_0^{\infty} \cos(2\pi k u) e^{-2\pi k_0 u} du, \end{aligned} \quad (2)$$

which, from the DAMPED EXPONENTIAL COSINE INTEGRAL, gives

$$\mathcal{F}[e^{-2\pi k_0|x|}] = \frac{1}{\pi} \frac{k_0}{k^2 + k_0^2}, \quad (3)$$

which is a LORENTZIAN FUNCTION.

see also DAMPED EXPONENTIAL COSINE INTEGRAL, EXPONENTIAL FUNCTION, LORENTZIAN FUNCTION

**Fourier Transform—Gaussian**

The FOURIER TRANSFORM of a GAUSSIAN FUNCTION  $f(x) \equiv e^{-ax^2}$  is given by

$$\begin{aligned}F(k) &= \int_{-\infty}^{\infty} e^{-ax^2} e^{ikx} dx \\ &= \int_{-\infty}^{\infty} e^{-ax^2} [\cos(kx) + i \sin(kx)] dx \\ &= \int_{-\infty}^{\infty} e^{-ax^2} \cos(kx) dx + i \int_{-\infty}^{\infty} e^{-ax^2} \sin(kx) dx.\end{aligned}$$

The second integrand is EVEN, so integration over a symmetrical range gives 0. The value of the first integral is given by Abramowitz and Stegun (1972, p. 302, equation 7.4.6)

$$F(k) = \sqrt{\frac{\pi}{a}} e^{-k^2/4a},$$

so a GAUSSIAN transforms to a GAUSSIAN.

see also GAUSSIAN FUNCTION

**References**

**Fourier Transform—Heaviside Step Function**

$$\mathcal{F}[H(x)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} H(x) dx = \frac{1}{2} \left[ \delta(k) - \frac{i}{\pi k} \right],$$

where  $H(x)$  is the HEAVISIDE STEP FUNCTION and  $\delta(k)$  is the DELTA FUNCTION.

see also HEAVISIDE STEP FUNCTION

**Fourier Transform—Lorentzian Function**

$$\mathcal{F} \left[ \frac{1}{\pi} \frac{\frac{1}{2}\Gamma}{(x-x_0)^2 + (\frac{1}{2}\Gamma)^2} \right] = e^{-2\pi i k x_0 - \Gamma \pi |k|}.$$

see also LORENTZIAN FUNCTION

**Fourier Transform—Ramp Function**

Let  $R(x)$  be the RAMP FUNCTION, then the FOURIER TRANSFORM of  $R(x)$  is given by

$$\mathcal{F}[R(x)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} R(x) dx = \pi i \delta'(2\pi k) - \frac{1}{4\pi^2 k^2},$$

where  $\delta'(x)$  is the DERIVATIVE of the DELTA FUNCTION.

see also RAMP FUNCTION

**Fourier Transform—Rectangle Function**

Let  $\Pi(x)$  be the RECTANGLE FUNCTION, then the FOURIER TRANSFORM is

$$\mathcal{F}[\Pi(x)] = \text{sinc}(\pi k),$$

where  $\text{sinc}(x)$  is the SINC FUNCTION.

see also RECTANGLE FUNCTION, SINC FUNCTION

**Fourier Transform—Sine**

$$\begin{aligned} \mathcal{F}[\sin(2\pi k_0 x)] &= \int_{-\infty}^{\infty} e^{-2\pi i k_0 x} \left( \frac{e^{2\pi i \nu_0 t} - e^{-2\pi i k_0 x}}{2i} \right) dx \\ &= \frac{1}{2} i \int_{-\infty}^{\infty} [-e^{-2\pi i(k-k_0)x} + e^{-2\pi i(k+k_0)x}] dt \\ &= \frac{1}{2} i [\delta(k+k_0) - \delta(k-k_0)], \end{aligned}$$

where  $\delta(x)$  is the DELTA FUNCTION.

see also FOURIER TRANSFORM—COSINE, SINE

**Fox's  $H$ -Function**

A very general function defined by

$$\begin{aligned} H(z) &= \mathbf{H}_{p,q}^{m,n} \left[ z \mid \begin{matrix} (a_1, \alpha_1), \dots, (a_p, \alpha_p) \\ (b_1, \beta_1), \dots, (b_p, \beta_p) \end{matrix} \right] \\ &= \frac{1}{2\pi i} \int_C \frac{\prod_{j=1}^m \Gamma(b_j - \beta_j s) \prod_{j=1}^n \Gamma(1 - a_j + \alpha_j s)}{\prod_{j=m+1}^p \Gamma(1 - b_j + \beta_j s) \prod_{j=n+1}^{qp} \Gamma(a_j - \alpha_j s)} z^s ds, \end{aligned}$$

where  $0 \leq m \leq q$ ,  $0 \leq n \leq p$ ,  $\alpha_j, \beta_j > 0$ , and  $a_j, b_j$  are COMPLEX NUMBERS such that the pole of  $\Gamma(b_j - \beta_j s)$  for  $j = 1, 2, \dots, m$  coincides with any POLE of  $\Gamma(1 - a_j + \alpha_j s)$  for  $j = 1, 2, \dots, n$ . In addition  $C$ , is a CONTOUR in the complex  $s$ -plane from  $\omega - i\infty$  to  $\omega + i\infty$  such that  $(b_j + k)/\beta_j$  and  $(a_j - 1 - k)/\alpha_j$  lie to the right and left of  $C$ , respectively.

**Frac**

see FRACTIONAL PART

**Fractal**

An object or quantity which displays SELF-SIMILARITY, in a somewhat technical sense, on all scales. The object need not exhibit *exactly* the same structure at all scales, but the same "type" of structures must appear on all scales. A plot of the quantity on a log-log graph versus scale then gives a straight line, whose slope is said to be the FRACTAL DIMENSION. The prototypical example for a fractal is the length of a coastline measured with different length RULERS. The shorter the RULER, the longer the length measured, a PARADOX known as the COASTLINE PARADOX.

## Fractal Dimension

The term "fractal dimension" is sometimes used to refer to what is more commonly called the CAPACITY DIMENSION (which is, roughly speaking, the exponent  $D$  in the expression  $n(\epsilon) = \epsilon^{-D}$ , where  $n(\epsilon)$  is the minimum number of OPEN SETS of diameter  $\epsilon$  needed to cover the set). However, it can more generally refer to any of the dimensions commonly used to characterize fractals (e.g., CAPACITY DIMENSION, CORRELATION DIMENSION, INFORMATION DIMENSION, LYAPUNOV DIMENSION, MINKOWSKI-BOULIGAND DIMENSION).

see also BOX COUNTING DIMENSION, CAPACITY DIMENSION, CORRELATION DIMENSION, FRACTAL DIMENSION, HAUSDORFF DIMENSION, INFORMATION DIMENSION, LYAPUNOV DIMENSION, MINKOWSKI-BOULIGAND DIMENSION, POINTWISE DIMENSION,  $q$ -DIMENSION

## Fractal Land

see CAROTID-KUNDALINI FRACTAL

## Fractal Process

A 1-D MAP whose increments are distributed according to a NORMAL DISTRIBUTION. Let  $y(t-\Delta t)$  and  $y(t+\Delta t)$  be values, then their correlation is given by the BROWN FUNCTION

$$r = 2^{2H-1} - 1.$$

When  $H = 1/2$ ,  $r = 0$  and the fractal process corresponds to 1-D Brownian motion. If  $H > 1/2$ , then  $r > 0$  and the process is called a PERSISTENT PROCESS. If  $H < 1/2$ , then  $r < 0$  and the process is called an ANTIPERSISTENT PROCESS.

see also ANTIPERSISTENT PROCESS, PERSISTENT PROCESS

**Fractal Sequence**

Given an INFINITIVE SEQUENCE  $\{x_n\}$  with associated array  $a(i, j)$ , then  $\{x_n\}$  is said to be a fractal sequence

1. If  $i + 1 = x_n$ , then there exists  $m < n$  such that  $i = x_m$ ,
2. If  $h < i$ , then, for every  $j$ , there is exactly one  $k$  such that  $a(i, j) < a(h, k) < a(i, j + 1)$ .

(As  $i$  and  $j$  range through  $N$ , the array  $A = a(i, j)$ , called the associative array of  $x$ , ranges through all of  $N$ .) An example of a fractal sequence is 1, 1, 1, 1, 2, 1, 2, 1, 3, 2, 1, 3, 2, 1, 3, 2, 1, 3, ....

If  $\{x_n\}$  is a fractal sequence, then the associated array is an INTERSPERSION. If  $x$  is a fractal sequence, then the UPPER-TRIMMED SUBSEQUENCE is given by  $\lambda(x) = x$ , and the LOWER-TRIMMED SUBSEQUENCE  $V(x)$  is another fractal sequence. The SIGNATURE of an IRRATIONAL NUMBER is a fractal sequence.

see also INFINITIVE SEQUENCE

**Fractal Valley**

see CAROTID-KUNDALINI FUNCTION

**Fraction**

A RATIONAL NUMBER expressed in the form  $a/b$ , where  $a$  is called the NUMERATOR and  $b$  is called the DENOMINATOR. A PROPER FRACTION is a fraction such that  $a/b < 1$ , and a LOWEST TERMS FRACTION is a fraction with common terms canceled out of the NUMERATOR and DENOMINATOR.

The Egyptians expressed their fractions as sums (and differences) of UNIT FRACTIONS. Conway and Guy (1999) give a table of Roman NOTATION for fractions, in which multiples of  $1/12$  (the UNCIA) were given separate names.

see also ADJACENT FRACTION, ANOMALOUS CANCELLATION, CONTINUED FRACTION, DENOMINATOR, EGYPTIAN FRACTION, FAREY SEQUENCE, GOLDEN RULE, HALF, LOWEST TERMS FRACTION, MEDIAN, NUMERATOR, PROPER FRACTION, PYTHAGOREAN FRACTION, QUARTER, RATIONAL NUMBER, UNIT FRACTION

**Fractional Calculus**

Denote the  $n$ th DERIVATIVE  $D^n$  and the  $n$ -fold INTEGRAL  $D^{-n}$ . Then

$$D^{-1}f(t) = \int_0^t f(\xi) d\xi. \quad (1)$$

Now, if

$$D^{-n}f(t) = \frac{1}{(n-1)!} \int_0^t (t-\xi)^{n-1} f(\xi) d\xi \quad (2)$$

is true for  $n$ , then

$$\begin{aligned} D^{-(n+1)}f(t) &= D^{-1} \left[ \frac{1}{(n-1)!} \int_0^t (t-\xi)^{n-1} f(\xi) d\xi \right] \\ &= \int_0^t \left[ \frac{1}{(n-1)!} \int_0^x (x-\xi)^{n-1} f(\xi) d\xi \right] dx. \end{aligned} \quad (3)$$

Interchanging the order of integration gives

$$D^{-(n+1)}f(t) = \frac{1}{n!} \int_0^t (t-\xi)^n f(\xi) d\xi. \quad (4)$$

But (2) is true for  $n = 1$ , so it is also true for all  $n$  by INDUCTION. The fractional integral of  $f(t)$  can then be defined by

$$D^{-\nu}f(t) = \frac{1}{\Gamma(\nu)} \int_0^t (t-\xi)^{\nu-1} f(\xi) d\xi, \quad (5)$$

where  $\Gamma(\nu)$  is the GAMMA FUNCTION.

The fractional integral can only be given in terms of elementary functions for a small number of functions. For example,

$$D^{-\nu}t^{-\lambda} = \frac{\Gamma(\lambda+1)}{\Gamma(\lambda+\nu+1)} t^{\lambda+\nu} \quad \text{for } \lambda > -1, \nu > 0 \quad (6)$$

$$D^{-\nu}e^{at} = \frac{1}{\Gamma(\nu)} e^{at} \int_0^t x^{\nu-1} e^{-ax} dx \equiv E_t(\nu, a), \quad (7)$$

where  $E_t(\nu, a)$  is the  $E_t$ -FUNCTION. The fractional derivative of  $f$  (if it exists) can be defined by

$$D^\mu f(t) = D^m [D^{-(m-\mu)} f(t)]. \quad (8)$$

An example is

$$\begin{aligned} D^\mu t^\lambda &= \frac{\Gamma(\lambda+1)}{\Gamma(\lambda+m-\mu+1)} \\ &= \frac{\Gamma(\lambda+1)}{\Gamma(\lambda-\mu+1)} t^{\lambda-\mu} \quad \text{for } \lambda > -1, \mu > 0 \end{aligned} \quad (9)$$

$$D^\rho E_t(\nu, a) = E_t(\nu - \rho, a) \quad \text{for } \nu > 0, \rho \neq 0. \quad (10)$$

It is always true that, for  $\mu, \nu > 0$ ,

$$D^{-\mu} D^{-\nu} f(t) = D^{-(\mu+\nu)}, \quad (11)$$

but *not* always true that

$$D^{\mu} D^{\nu} = D^{\mu+\nu}. \quad (12)$$

### Fractional Derivative

see FRACTIONAL CALCULUS

### Fractional Differential Equation

The solution to the differential equation

$$[D^{2\nu} + aD^{\nu} + bD^0]y(t) = 0$$

is

$$y(t) = \begin{cases} e_{\alpha}(t) - e_{\beta}(t) & \text{for } \alpha \neq \beta \\ te^{\alpha t}, \sum_{k=-1}^{q-1} \alpha^k (q - |k|) D^{1-(k+1)\nu} (te^{\alpha t}) & \text{for } \alpha = \beta \neq 0 \\ \frac{t^{2\nu-1}}{\Gamma(2\nu)} & \text{for } \alpha = \beta = 0, \end{cases}$$

where

$$q = \frac{1}{\nu}$$

$$e_{\beta}(t) = \sum_{k=0}^{q-1} \beta^{q-k-1} E_t(-k\nu, \beta^q),$$

$E_t(a, x)$  is the  $E_t$ -FUNCTION, and  $\Gamma(n)$  is the GAMMA FUNCTION.

### Fractran

Fractran is an algorithm applied to a given list  $f_1, f_2, \dots, f_k$  of FRACTIONS. Given a starting INTEGER  $N$ , the Fractran algorithm proceeds by repeatedly multiplying the integer at a given stage by the first element  $f_i$  given an integer PRODUCT. The algorithm terminates when there is no such  $f_i$ .

The list

$$\frac{17}{91}, \frac{78}{85}, \frac{19}{51}, \frac{23}{38}, \frac{29}{33}, \frac{77}{29}, \frac{95}{23}, \frac{77}{19}, \frac{1}{17}, \frac{11}{13}, \frac{13}{11}, \frac{15}{2}, \frac{1}{7}, \frac{55}{1}$$

with starting integer  $N = 2$  generates a sequence 2, 15, 825, 725, 1925, 2275, 425, 390, 330, 290, 770, .... Conway (1987) showed that the only other powers of 2 which occur are those with PRIME exponent:  $2^2, 2^3, 2^5, 2^7, \dots$

**Framework**

Consider a finite collection of points  $p = (p_1, \dots, p_n)$ ,  $p_i \in \mathbb{R}^d$  EUCLIDEAN SPACE (known as a CONFIGURATION) and a graph  $G$  whose VERTICES correspond to pairs of points that are constrained to stay the same distance apart. Then the graph  $G$  together with the configuration  $p$ , denoted  $G(p)$ , is called a framework.

see also BAR (EDGE), CONFIGURATION, RIGID

**Franklin Magic Square**

52	61	4	13	20	29	36	45
14	3	62	51	46	35	30	19
53	60	5	12	21	28	37	44
11	6	59	54	43	38	27	22
55	58	7	10	23	26	39	42
9	8	57	56	41	40	25	24
50	63	2	15	18	31	34	47
16	1	64	49	48	33	32	17

Benjamin Franklin constructed the above  $8 \times 8$  PANMAGIC SQUARE having MAGIC CONSTANT 260. Any half-row or half-column in this square totals 130, and the four corners plus the middle total 260. In addition, bent diagonals (such as 52-3-5-54-10-57-63-16) also total 260 (Madachy 1979, p. 87).

**Fréchet Bounds**

Any bivariate distribution function with marginal distribution functions  $F$  and  $G$  satisfies

$$\max\{F(x) + G(y) - 1, 0\} \leq H(x, y) \leq \min\{F(x), G(y)\}.$$

**Fréchet Derivative**

A function  $f$  is Fréchet differentiable at  $a$  if

$$\lim_{x \rightarrow a} \frac{f(x) - f(a)}{x - a}$$

exists. This is equivalent to the statement that  $\phi$  has a removable DISCONTINUITY at  $a$ , where

$$\phi(x) \equiv \frac{f(x) - f(a)}{x - a}.$$

Every function which is Fréchet differentiable is also Carathéodory differentiable.

see also CARATHÉODORY DERIVATIVE, DERIVATIVE

**Fréchet Space**

A complete metrizable SPACE, sometimes also with the restriction that the space be locally convex.

**Fredholm Integral Equation of the First Kind**

An INTEGRAL EQUATION of the form

$$f(x) = \int_{-\infty}^{\infty} K(x, t)\phi(t) dt$$

$$\phi(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{F(\omega)}{K(\omega)} e^{-i\omega x} d\omega.$$

#### Free

When referring to a planar object, "free" means that the object is regarded as capable of being picked up out of the plane and flipped over. As a result, MIRROR IMAGES are equivalent for free objects.

A free abstract mathematical object is generated by  $n$  elements in a "free manner," i.e., such that the  $n$  elements satisfy no nontrivial relations among themselves. To make this more formal, an algebraic GADGET  $X$  is freely generated by a SUBSET  $G$  if, for any function  $f : G \rightarrow Y$  where  $Y$  is any other algebraic GADGET, there exists a unique HOMOMORPHISM (which has different meanings depending on what kind of GADGETS you're dealing with)  $g : X \rightarrow Y$  such that  $g$  restricted to  $G$  is  $f$ .

If the algebraic GADGETS are VECTOR SPACES, then  $G$  freely generates  $X$  IFF  $G$  is a BASIS for  $X$ . If the algebraic GADGETS are ABELIAN GROUPS, then  $G$  freely generates  $X$  IFF  $X$  is a DIRECT SUM of the INTEGERS, with  $G$  consisting of the standard BASIS.

see also FIXED, GADGET, MIRROR IMAGE, RANK

#### Free Group

The generators of a group  $G$  are defined to be the smallest subset of group elements such that all other elements of  $G$  can be obtained from them and their inverses. A GROUP is a free group if no relation exists between its generators (other than the relationship between an element and its inverse required as one of the defining properties of a group). For example, the additive group of whole numbers is free with a single generator, 1.

see also FREE SEMIGROUP

#### Free Semigroup

A SEMIGROUP with a noncommutative product in which no PRODUCT can ever be expressed more simply in terms of other ELEMENTS.

see also FREE GROUP, SEMIGROUP

#### Free Variable

An occurrence of a variable in a LOGIC FORMULA which is not inside the scope of a QUANTIFIER.

see also BOUND, SENTENCE

#### Freemish Crate

An IMPOSSIBLE FIGURE box which can be drawn but not built.

 von Seggern, D. *CRC Standard Curves and Surfaces*. Boca Raton, FL: CRC Press, p. 304, 1993.

#### Fresnel Integrals

In physics, the Fresnel integrals are most often defined by

$$\begin{aligned} C(u) + iS(u) &\equiv \int_0^u e^{i\pi x^2/2} dx \\ &= \int_0^u \cos(\tfrac{1}{2}\pi x^2) dx + i \int_0^u \sin(\tfrac{1}{2}\pi x^2) dx, \end{aligned} \quad (1)$$

so

$$C(u) \equiv \int_0^u \cos(\tfrac{1}{2}\pi x^2) dx \quad (2)$$

$$S(u) \equiv \int_0^u \sin(\tfrac{1}{2}\pi x^2) dx. \quad (3)$$

They satisfy

$$C(\pm\infty) = -\tfrac{1}{2} \quad (4)$$

$$S(\pm\infty) = \tfrac{1}{2}. \quad (5)$$

Related functions are defined as

$$C_1(z) \equiv \sqrt{\frac{2}{\pi}} \int_0^x \cos t^2 dt \quad (6)$$

$$S_1(z) \equiv \sqrt{\frac{2}{\pi}} \int_0^x \sin t^2 dt \quad (7)$$

$$C_2(z) \equiv \frac{1}{\sqrt{2\pi}} \int \frac{\cos t}{\sqrt{t}} dt \quad (8)$$

$$S_2(z) \equiv \frac{1}{\sqrt{2\pi}} \int \frac{\sin t}{\sqrt{t}} dt. \quad (9)$$

An asymptotic expansion for  $x \gg 1$  gives

$$C(u) \approx \frac{1}{2} + \frac{1}{\pi u} \sin(\tfrac{1}{2}\pi u^2) \quad (10)$$

$$S(u) \approx \frac{1}{2} - \frac{1}{\pi u} \cos(\tfrac{1}{2}\pi u^2). \quad (11)$$

Therefore, as  $u \rightarrow \infty$ ,  $C(u) = 1/2$  and  $S(u) = 1/2$ . The Fresnel integrals are sometimes alternatively defined as

$$x(t) = \int_0^t \cos(v^2) dv \quad (12)$$

$$y(t) = \int_0^t \sin(v^2) dv. \quad (13)$$

Letting  $x \equiv v^2$  so  $dx = 2v dv = 2\sqrt{x} dv$ , and  $dv = x^{-1/2} dx/2$

$$x(t) = \frac{1}{2} \int_0^{\sqrt{t}} x^{-1/2} \cos x dx \quad (14)$$

$$y(t) = \frac{1}{2} \int_0^{\sqrt{t}} x^{-1/2} \sin x dx. \quad (15)$$

In this form, they have a particularly simple expansion in terms of SPHERICAL BESSEL FUNCTIONS OF THE FIRST KIND. Using

$$j_0(x) = \frac{\sin x}{x} \quad (16)$$

$$n_1(x) = -j_{-1}(x) = -\frac{\cos x}{x}, \quad (17)$$

where  $n_1(x)$  is a SPHERICAL BESSEL FUNCTION OF THE SECOND KIND

$$\begin{aligned} x(t^2) &= -\frac{1}{2} \int_0^t n_1(x) x^{1/2} dx \\ &= \frac{1}{2} \int_0^t j_{-1}(x) x^{1/2} dx = x^{1/2} \sum_{n=0}^{\infty} j_{2n}(x) \end{aligned} \quad (18)$$

$$\begin{aligned} y(t^2) &= \frac{1}{2} \int_0^t j_0(x) x^{1/2} dx \\ &= x^{1/2} \sum_{n=0}^{\infty} j_{2n+1}(x). \end{aligned} \quad (19)$$

#### Fresnel's Wave Surface

see FRESNEL'S ELASTICITY SURFACE

#### Frey Curve

Let  $a^p + b^p = c^p$  be a solution to FERMAT'S LAST THEOREM. Then the corresponding Frey curve is

$$y^2 = x(x - a^p)(x + b^p). \quad (1)$$

Frey showed that such curves cannot be MODULAR, so if the TANIYAMA-SHIMURA CONJECTURE were true, Frey

curves couldn't exist and FERMAT'S LAST THEOREM would follow with  $b$  EVEN and  $a \equiv -1 \pmod{4}$ . Frey curves are SEMISTABLE. Invariants include the DISCRIMINANT

$$(a^p - 0)^2(-b^p - 0)[a^p - (-b)^p]^2 = a^{2p}b^{2p}c^{2p}. \quad (2)$$

The MINIMAL DISCRIMINANT is

$$\Delta = 2^{-8} a^{2p} b^{2p} c^{2p}, \quad (3)$$

the CONDUCTOR is

$$N = \prod_{l|abc} l, \quad (4)$$

and the  $j$ -INVARIANT is

$$j = \frac{2^8(a^{2p} + b^{2p} + a^p b^p)^3}{a^{2p} b^{2p} c^{2p}} = \frac{2^8(c^{2p} - b^p c^p)^3}{(abc)^{2p}}. \quad (5)$$

#### Frey Elliptic Curve

see FREY CURVE

#### Friday the Thirteenth

The Gregorian calendar follows a pattern of leap years which repeats every 400 years. There are 4,800 months in 400 years, so the 13th of the month occurs 4,800 times in this interval. The number of times the 13th occurs on each weekday is given in the table below. As shown by Brown (1933), the thirteenth of the month is slightly more likely to be on a Friday than on any other day.

Day	Number of 13s	Fraction
Sunday	687	14.31%
Monday	685	14.27%
Tuesday	685	14.27%
Wednesday	687	14.31%
Thursday	684	14.25%
Friday	688	14.33%
Saturday	684	14.25%

see also 13, WEEKDAY

Anderson, C. W. and Hickerson, D. Problem 6020. "Friendly Integers." *Amer. Math. Monthly* **84**, 65–66, 1977.

**Friendly Giant Group**

see MONSTER GROUP

**Friendly Pair**

Define

$$\Sigma(n) \equiv \frac{\sigma(n)}{n},$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. Then a PAIR of distinct numbers  $(k, m)$  is a friendly pair (and  $k$  is said to be a FRIEND of  $m$ ) if

$$\Sigma(k) = \Sigma(m).$$

For example, 4320 and 4680 are a friendly pair, since  $\sigma(4320) = 15120$ ,  $\sigma(4680) = 16380$ , and

$$\begin{aligned}\Sigma(4320) &\equiv \frac{15120}{4320} = \frac{7}{2} \\ \Sigma(4680) &\equiv \frac{16380}{4680} = \frac{7}{2}.\end{aligned}$$

Numbers which do not have FRIENDS are called SOLITARY NUMBERS. SOLITARY NUMBERS satisfy  $(\sigma(n), n) = 1$ , where  $(a, b)$  is the GREATEST COMMON DIVISOR of  $a$  and  $b$ .

see also ALIQUOT SEQUENCE, FRIEND, SOLITARY NUMBER

**Frobenius-König Theorem**

The PERMANENT of an  $n \times n$  MATRIX with all entries either 0 or 1 is 0 IFF the MATRIX contains an  $r \times s$  submatrix of 0s with  $r + s = n + 1$ . This result follows from the KÖNIG-EGEVÁRY THEOREM.

see also KÖNIG-EGEVÁRY THEOREM, PERMANENT

**Frobenius Map**

A map  $x \mapsto x^p$  where  $p$  is a PRIME.

**Frobenius Method**

If  $x_0$  is an ordinary point of the ORDINARY DIFFERENTIAL EQUATION, expand  $y$  in a TAYLOR SERIES about  $x_0$ , letting

$$y = \sum_{n=0}^{\infty} a_n x^n. \quad (1)$$

Plug  $y$  back into the ODE and group the COEFFICIENTS by POWER. Now, obtain a RECURRENCE RELATION for the  $n$ th term, and write the TAYLOR SERIES in terms of the  $a_n$ s. Expansions for the first few derivatives are

$$y = \sum_{n=0}^{\infty} a_n x^n \quad (2)$$

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n \quad (3)$$

$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)(n+1) a_{n+2} x^n. \quad (4)$$

If  $x_0$  is a regular singular point of the ORDINARY DIFFERENTIAL EQUATION,

$$P(x)y'' + Q(x)y' + R(x)y = 0, \quad (5)$$

solutions may be found by the Frobenius method or by expansion in a LAURENT SERIES. In the Frobenius method, assume a solution of the form

$$y = x^k \sum_{n=0}^{\infty} a_n x^n, \quad (6)$$

so that

$$y = x^k \sum_{n=0}^{\infty} a_n x^n = \sum_{n=0}^{\infty} a_n x^{n+k} \quad (7)$$

$$y' = \sum_{n=0}^{\infty} a_n (n+k) x^{k+n-1} \quad (8)$$

$$y'' = \sum_{n=0}^{\infty} a_n (n+k)(n+k-1) x^{k+n-2}. \quad (9)$$

Now, plug  $y$  back into the ODE and group the COEFFICIENTS by POWER to obtain a recursion FORMULA for the  $a_n$ th term, and then write the TAYLOR SERIES in terms of the  $a_n$ s. Equating the  $a_0$  term to 0 will produce the so-called INDICIAL EQUATION, which will give the allowed values of  $k$  in the TAYLOR SERIES.

FUCHS'S THEOREM guarantees that at least one POWER series solution will be obtained when applying the Frobenius method if the expansion point is an ordinary,

or regular, SINGULAR POINT. For a regular SINGULAR POINT, a LAURENT SERIES expansion can also be used. Expand  $y$  in a LAURENT SERIES, letting

$$y = c_{-n}x^{-n} + \dots + c_{-1}x^{-1} + c_0 + c_1x + \dots + c_nx^n + \dots \quad (10)$$

Plug  $y$  back into the ODE and group the COEFFICIENTS by POWER. Now, obtain a recurrence FORMULA for the  $c_n$ th term, and write the TAYLOR EXPANSION in terms of the  $c_n$ s.

see also FUCHS'S THEOREM, ORDINARY DIFFERENTIAL EQUATION

Ott, E. *Chaos in Dynamical Systems*. New York: Cambridge University Press, p. 51, 1993.

### Frobenius Pseudoprime

Let  $f(x)$  be a MONIC POLYNOMIAL of degree  $d$  with discriminant  $\Delta$ . Then an ODD INTEGER  $n$  with  $(n, f(0)\Delta) = 1$  is called a Frobenius pseudoprime with respect to  $f(x)$  if it passes a certain algorithm given by Grantham (1996). A Frobenius pseudoprime with respect to a POLYNOMIAL  $f(x) \in \mathbb{Z}[x]$  is then a composite Frobenius probably prime with respect to the POLYNOMIAL  $x - a$ .

While 323 is the first LUCAS PSEUDOPRIME with respect to the Fibonacci polynomial  $x^2 - x - 1$ , the first Frobenius pseudoprime is 5777. If  $f(x) = x^3 - rx^2 + sx - 1$ , then any Frobenius pseudoprime  $n$  with respect to  $f(x)$  is also a PERRIN PSEUDOPRIME. Grantham (1997) gives a test based on Frobenius pseudoprimes which is passed by COMPOSITE NUMBERS with probability at most  $1/7710$ .

**Frustum**

The portion of a solid which lies between two PARALLEL PLANES cutting the solid. Degenerate cases are obtained for finite solids by cutting with a single PLANE only.

see also CONICAL FRUSTUM, PYRAMIDAL FRUSTUM, SPHERICAL SEGMENT

**Fubini Principle**

If the average number of envelopes per pigeonhole is  $a$ , then some pigeonhole will have at least  $a$  envelopes. Similarly, there must be a pigeonhole with at most  $a$  envelopes.

see also PIGEONHOLE PRINCIPLE

**Fuchsian System**

A system of linear differential equations

$$\frac{dy}{dz} = A(z)y,$$

with  $A(z)$  an ANALYTIC  $n \times n$  MATRIX, for which the MATRIX  $A(z)$  is ANALYTIC in  $\mathbb{C} \setminus \{a_1, \dots, a_N\}$  and has a POLE of order 1 at  $a_j$  for  $j = 1, \dots, N$ . A system is Fuchsian IFF there exist  $n \times n$  matrices  $B_1, \dots, B_N$  with entries in  $\mathbb{Z}$  such that

$$A(z) = \sum_{j=1}^N \frac{B_j}{z - a_j}$$

$$\sum_{j=1}^N B_j = v.$$

**Fuchs's Theorem**

At least one POWER SERIES solution will be obtained when applying the FROBENIUS METHOD if the expansion point is an ordinary, or regular, SINGULAR POINT. The number of ROOTS is given by the ROOTS of the INDICIAL EQUATION.

### Full Width at Half Maximum

The full width at half maximum (FWHM) is a parameter commonly used to describe the width of a "bump" on a curve or function. It is given by the distance between points on the curve at which the function reaches half its maximum value. The following table gives the analytic and numerical full widths for several common curves.

Function	Formula	FWHM
Bartlett	$1 - \frac{ x }{a}$	$a$
Blackman		$0.810957a$
Connes	$\left(1 - \frac{x^2}{a^2}\right)$	$\sqrt{4 - 2\sqrt{2}}a$
Cosine	$\cos\left(\frac{\pi x}{2a}\right)$	$\frac{4}{3}a$
Gaussian	$e^{-x^2/(2\sigma^2)}$	$2\sqrt{2 \ln 2} \sigma$
Hamming		$1.05543a$
Hanning		$a$
Lorentzian	$\frac{\frac{1}{2}\Gamma}{x^2 + (\frac{1}{2}\Gamma)^2}$	$\Gamma$
Welch	$1 - \frac{x^2}{a^2}$	$\sqrt{2}a$

see also APODIZATION FUNCTION, MAXIMUM

### Fuller Dome

see GEODESIC DOME

### Function

A way of associating unique objects to every point in a given SET. A function from  $A$  to  $B$  is an object  $f$  such that for every  $a \in A$ , there is a unique object  $f(a) \in B$ . Examples of functions include  $\sin x$ ,  $x$ ,  $x^2$ , etc. The term MAP is synonymous with function.

Poincaré remarked with regard to the proliferation of pathological functions, "Formerly, when one invented a new function, it was to further some practical purpose; today one invents them in order to make incorrect the

reasoning of our fathers, and nothing more will ever be accomplished by these inventions."

### Function Field

see ALGEBRAIC FUNCTION FIELD

### Function Space

$f(I)$  is the collection of all real-valued continuous functions defined on some interval  $I$ .  $f^{(n)}(I)$  is the collection of all functions  $\in f(I)$  with continuous  $n$ th DERIVATIVES. A function space is a TOPOLOGICAL VECTOR SPACE whose "points" are functions.

see also FUNCTIONAL, FUNCTIONAL ANALYSIS, OPERATOR

### Functional

A mapping between FUNCTION SPACES if the range is on the REAL LINE or in the COMPLEX PLANE.

see also COERCIVE FUNCTIONAL, CURRENT, ELLIPTIC FUNCTIONAL, GENERALIZED FUNCTION, LAX-MILGRAM THEOREM, OPERATOR, RIESZ REPRESENTATION THEOREM

### Functional Analysis

A branch of mathematics concerned with infinite dimensional spaces (mainly FUNCTION SPACES) and mappings between them. The SPACES may be of different, and possibly INFINITE, DIMENSIONS. These mappings are called OPERATORS or, if the range is on the REAL line or in the COMPLEX PLANE, FUNCTIONALS.

see also FUNCTIONAL, OPERATOR

### Functional Calculus

An early name for CALCULUS OF VARIATIONS.

### Functional Derivative

A generalization of the concept of the DERIVATIVE to GENERALIZED FUNCTIONS.

### Functor

A function between CATEGORIES which maps objects to objects and MORPHISMS to MORPHISMS. Functors exist in both covariant and contravariant types.

see also CATEGORY, EILENBERG-STEENROD AXIOMS, MORPHISM, SCHUR FUNCTOR

### Fundamental Class

The canonical generator of the nonvanishing HOMOLOGY GROUP on a TOPOLOGICAL MANIFOLD.

see also CHERN NUMBER, PONTRYAGIN NUMBER, STIEFEL-WHITNEY NUMBER

### Fundamental Continuity Theorem

Given two POLYNOMIALS of the same order in one variable where the first  $p$  COEFFICIENTS (but not the first  $p - 1$ ) are 0 and the COEFFICIENTS of the second approach the corresponding COEFFICIENTS of the first as limits, then the second POLYNOMIAL will have exactly  $p$  roots that increase indefinitely. Furthermore, exactly  $k$  ROOTS of the second will approach each ROOT of multiplicity  $k$  of the first as a limit.

**Fundamental Forms**

There are three types of so-called fundamental forms. The most important are the first and second (since the third can be expressed in terms of these). The fundamental forms are extremely important and useful in determining the metric properties of a surface, such as LINE ELEMENT, AREA ELEMENT, NORMAL CURVATURE, GAUSSIAN CURVATURE, and MEAN CURVATURE. Let  $M$  be a REGULAR SURFACE with  $\mathbf{v}_p, \mathbf{w}_p$  points on the TANGENT SPACE  $M_p$  of  $M$ . Then the first fundamental form is the INNER PRODUCT of tangent vectors,

$$\mathbf{I}(\mathbf{v}_p, \mathbf{w}_p) = \mathbf{v}_p \cdot \mathbf{w}_p. \quad (1)$$

For  $M \in \mathbb{R}^3$ , the second fundamental form is the symmetric bilinear form on the TANGENT SPACE  $M_p$ ,

$$\mathbf{II}(\mathbf{v}_p, \mathbf{w}_p) = S(\mathbf{v}_p) \cdot \mathbf{w}_p, \quad (2)$$

where  $S$  is the SHAPE OPERATOR. The third fundamental form is given by

$$\mathbf{III}(\mathbf{v}_p, \mathbf{w}_p) = S(\mathbf{v}_p) \cdot S(\mathbf{w}_p). \quad (3)$$

The first and second fundamental forms satisfy

$$\mathbf{I}(a\mathbf{x}_u + b\mathbf{x}_v, a\mathbf{x}_u + b\mathbf{x}_v) = Ea^2 + 2Fab + Gb^2 \quad (4)$$

$$\mathbf{II}(a\mathbf{x}_u + b\mathbf{x}_v, a\mathbf{x}_u + b\mathbf{x}_v) = ea^2 + 2fab + gb^2, \quad (5)$$

and so their ratio is simply the NORMAL CURVATURE

$$\kappa(\mathbf{v}_p) = \frac{\mathbf{II}(\mathbf{v}_p)}{\mathbf{I}(\mathbf{v}_p)} \quad (6)$$

for any nonzero TANGENT VECTOR. The third fundamental form is given in terms of the first and second forms by

$$\mathbf{III} - 2H\mathbf{II} + K\mathbf{I} = 0, \quad (7)$$

where  $H$  is the MEAN CURVATURE and  $K$  is the GAUSSIAN CURVATURE.

The first fundamental form (or LINE ELEMENT) is given explicitly by the RIEMANNIAN METRIC

$$ds^2 = E du^2 + 2F du dv + G dv^2. \quad (8)$$

It determines the ARC LENGTH of a curve on a surface. The coefficients are given by

$$E = \mathbf{x}_{uu} = \left| \frac{\partial \mathbf{x}}{\partial u} \right|^2 \quad (9)$$

$$F = \mathbf{x}_{uv} = \frac{\partial \mathbf{x}}{\partial u} \cdot \frac{\partial \mathbf{x}}{\partial v} \quad (10)$$

$$G = \mathbf{x}_{vv} = \left| \frac{\partial \mathbf{x}}{\partial v} \right|^2. \quad (11)$$

The coefficients are also denoted  $g_{uu} = E$ ,  $g_{uv} = F$ , and  $g_{vv} = G$ . In CURVILINEAR COORDINATES (where  $F = 0$ ), the quantities

$$h_u \equiv \sqrt{g_{uu}} = \sqrt{E} \quad (12)$$

$$h_v \equiv \sqrt{g_{vv}} = \sqrt{G} \quad (13)$$

are called SCALE FACTORS.

The second fundamental form is given explicitly by

$$e du^2 + 2f du dv + g dv^2 \quad (14)$$

where

$$e = \sum_i X_i \frac{\partial^2 x_i}{\partial u^2} \quad (15)$$

$$f = \sum_i X_i \frac{\partial^2 x_i}{\partial u \partial v} \quad (16)$$

$$g = \sum_i X_i \frac{\partial^2 x_i}{\partial v^2}, \quad (17)$$

and  $X_i$  are the DIRECTION COSINES of the surface normal. The second fundamental form can also be written

$$e = -\mathbf{N}_u \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uu} \quad (18)$$

$$f = -\mathbf{N}_v \cdot \mathbf{x}_u = \mathbf{N} \cdot \mathbf{x}_{uv} = \mathbf{N}_{vu} \cdot \mathbf{x}_{vu} \\ = -\mathbf{N}_u \cdot \mathbf{x}_v \quad (19)$$

$$g = -\mathbf{N}_v \cdot \mathbf{x}_v = \mathbf{N} \cdot \mathbf{x}_{vv}, \quad (20)$$

where  $\mathbf{N}$  is the NORMAL VECTOR, or

$$e = \frac{\det(\mathbf{x}_{uu}, \mathbf{x}_u, \mathbf{x}_v)}{\sqrt{EG - F^2}} \quad (21)$$

$$f = \frac{\det(\mathbf{x}_{uv}, \mathbf{x}_u, \mathbf{x}_v)}{\sqrt{EG - F^2}} \quad (22)$$

$$g = \frac{\det(\mathbf{x}_{vv}, \mathbf{x}_u, \mathbf{x}_v)}{\sqrt{EG - F^2}}. \quad (23)$$

### Fundamental Group

The fundamental group of a CONNECTED SET  $S$  is the QUOTIENT GROUP of the GROUP of all paths with initial and final points at a given point  $P$  and the SUBGROUP of all paths HOMOTOPIC to the degenerate path consisting of the point  $P$ .

The fundamental group of the CIRCLE is the INFINITE CYCLIC GROUP. Two fundamental groups having different points  $P$  are ISOMORPHIC. If the fundamental group consists only of the identity element, then the set  $S$  is simply connected.

see also MILNOR'S THEOREM

### Fundamental Homology Class

see also FUNDAMENTAL CLASS

### Fundamental Lemma of Calculus of Variations

If

$$\int_a^b M(x)h(x) dx = 0$$

$\forall h(x)$  with CONTINUOUS second PARTIAL DERIVATIVES, then

$$M(x) = 0$$

on the OPEN INTERVAL  $(a, b)$ .

### Fundamental System

A set of ALGEBRAIC INVARIANTS for a QUANTIC such that any invariant of the QUANTIC is expressible as a POLYNOMIAL in members of the set. In 1868, Gordan proved the existence of finite fundamental systems of algebraic invariants and covariants for any binary QUANTIC. In 1890, Hilbert (1890) proved the HILBERT BASIS THEOREM, which is a finiteness theorem for the related concept of SYZYGIES.

see also HILBERT BASIS THEOREM, SYZGY

### Fundamental Theorem of Algebra

Every POLYNOMIAL equation having COMPLEX COEFFICIENTS and degree  $\geq 1$  has at least one COMPLEX ROOT. This theorem was first proven by Gauss. It is equivalent to the statement that a POLYNOMIAL  $P(z)$  of degree  $n$  has  $n$  values of  $z$  (some of them possibly degenerate) for which  $P(z) = 0$ . An example of a POLYNOMIAL with a single ROOT of multiplicity  $> 1$  is  $z^2 - 2z + 1 = (z - 1)(z - 1)$ , which has  $z = 1$  as a ROOT of multiplicity 2.

### Fundamental Theorems of Calculus

The first fundamental theorem of calculus states that, if  $f$  is CONTINUOUS on the CLOSED INTERVAL  $[a, b]$  and  $F$  is the ANTIDERIVATIVE (INDEFINITE INTEGRAL) of  $f$  on  $[a, b]$ , then

$$\int_a^b f(x) dx = F(b) - F(a). \quad (1)$$

The second fundamental theorem of calculus lets  $f$  be CONTINUOUS on an OPEN INTERVAL  $I$  and lets  $a$  be any point in  $I$ . If  $F$  is defined by

$$F(x) = \int_a^x f(t) dt, \quad (2)$$

then

$$F'(x) = f(x) \quad (3)$$

at each point in  $I$ .

The complex fundamental theorem of calculus states that if  $f(z)$  has a CONTINUOUS ANTIDERIVATIVE  $F(z)$  in a region  $R$  containing a parameterized curve  $\gamma : z = z(t)$  for  $\alpha \leq t \leq \beta$ , then

$$\int_{\gamma} f(z) dz = F(z(\beta)) - F(z(\alpha)). \quad (4)$$

see also CALCULUS, DEFINITE INTEGRAL, INDEFINITE INTEGRAL, INTEGRAL

### Fundamental Theorem of Curves

The CURVATURE and TORSION functions along a SPACE CURVE determine it up to an orientation-preserving ISOMETRY.

**Fundamental Theorem of Directly Similar Figures**

Let  $F_0$  and  $F_1$  denote two directly similar figures in the plane, where  $P_1 \in F_1$  corresponds to  $P_0 \in F_0$  under the given similarity. Let  $r \in (0, 1)$ , and define  $F_r = \{(1-r)P_0 + rP_1 : P_0 \in F_0\}$ . Then  $F_r$  is also directly similar to  $F_0$ .

**Fundamental Unit**

In a real QUADRATIC FIELD, there exists a special UNIT  $\eta$  known as the fundamental unit such that all units  $\rho$  are given by  $\rho = \pm\eta^m$ , for  $m = 0, \pm 1, \pm 2, \dots$ . The following table gives the fundamental units for the first few real quadratic fields.

$d$	$\eta(d)$	$d$	$\eta(d)$
2	$1 + \sqrt{2}$	51	$50 + 7\sqrt{51}$
3	$2 + \sqrt{3}$	53	$\frac{1}{2}(7 + \sqrt{53})$
5	$\frac{1}{2}(1 + \sqrt{5})$	55	$89 + 12\sqrt{55}$
6	$5 + 2\sqrt{6}$	57	$151 + 20\sqrt{57}$
7	$8 + 3\sqrt{7}$	58	$99 + 13\sqrt{58}$
10	$3 + \sqrt{10}$	59	$530 + 69\sqrt{59}$
11	$10 + 3\sqrt{11}$	61	$\frac{1}{2}(39 + 5\sqrt{61})$
13	$\frac{1}{2}(3 + \sqrt{13})$	62	$63 + 8\sqrt{62}$
14	$15 + 4\sqrt{14}$	65	$8 + \sqrt{65}$
15	$4 + \sqrt{15}$	66	$65 + 8\sqrt{66}$
17	$4 + \sqrt{17}$	67	$48842 + 5967\sqrt{67}$
19	$170 + 39\sqrt{19}$	69	$\frac{1}{2}(25 + 3\sqrt{69})$
21	$\frac{1}{2}(5 + \sqrt{21})$	70	$251 + 30\sqrt{70}$
22	$197 + 42\sqrt{22}$	71	$3480 + 413\sqrt{71}$
23	$24 + 5\sqrt{23}$	73	$1068 + 125\sqrt{73}$
26	$5 + \sqrt{26}$	74	$43 + 5\sqrt{74}$
29	$\frac{1}{2}(5 + \sqrt{29})$	77	$\frac{1}{2}(9 + \sqrt{77})$
30	$11 + 2\sqrt{30}$	78	$53 + 6\sqrt{78}$
31	$1520 + 273\sqrt{31}$	79	$80 + 9\sqrt{79}$
33	$5 + 4\sqrt{33}$	82	$9 + \sqrt{82}$
34	$35 + 6\sqrt{34}$	83	$82 + 9\sqrt{83}$
35	$6 + \sqrt{35}$	85	$\frac{1}{2}(9 + \sqrt{85})$
37	$6 + \sqrt{37}$	86	$10405 + 1122\sqrt{86}$
38	$37 + 6\sqrt{38}$	87	$28 + 3\sqrt{87}$
39	$25 + 4\sqrt{39}$	89	$501 + 54\sqrt{89}$
41	$32 + 5\sqrt{41}$	91	$1574 + 165\sqrt{91}$
42	$13 + 2\sqrt{42}$	93	$\frac{1}{2}(29 + 3\sqrt{93})$
43	$3482 + 531\sqrt{43}$	95	$39 + 4\sqrt{95}$
46	$24335 + 3588\sqrt{46}$	97	$5604 + 569\sqrt{97}$
47	$48 + 7\sqrt{47}$

see FULL WIDTH AT HALF MAXIMUM

## G

## g-Function

see RAMANUJAN g- AND G-FUNCTIONS

## G-Function

Defined in Whittaker and Watson (1990, p. 264) and also called the BARNES G-FUNCTION.

$$G(z+1) \equiv (2\pi)^{z/2} e^{-[z(z+1)+\gamma z^2]/2} \times \prod_{n=1}^{\infty} \left[ \left(1 + \frac{z}{n}\right)^n e^{-z+z^2/(2n)} \right], \quad (1)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT. This is an ANALYTIC CONTINUATION of the  $G$  function defined in the construction of the GLAISHER-KINKELIN CONSTANT

$$G(n+1) \equiv \frac{(n!)^n}{K(n+1)}, \quad (2)$$

which has the special values

$$G(n) = \begin{cases} 0 & \text{if } n = 0, -1, -2, \dots \\ 1 & \text{if } n = 1 \\ 0!1!2! \dots (n-2)! & \text{if } n = 2, 3, 4, \dots \end{cases} \quad (3)$$

for INTEGER  $n$ . This function is what Sloane and Plouffe (1995) call the SUPERFACTORIAL, and the first few values for  $n = 1, 2, \dots$  are 1, 1, 1, 2, 12, 288, 34560, 24883200, 125411328000, 5056584744960000, ... (Sloane's A000178).

The  $G$ -function is the reciprocal of the DOUBLE GAMMA FUNCTION. It satisfies

$$G(z+1) = \Gamma(z)G(z) \quad (4)$$

$$\frac{(n!)^n}{G(n+1)} = 1^1 \cdot 2^2 \cdot 3^3 \dots n^n \quad (5)$$

$$\frac{G'(z+1)}{G(z+1)} = \frac{1}{2} \ln(2\pi) - \frac{1}{2} - z + z \frac{\Gamma'(z)}{\Gamma(z)} \quad (6)$$

$$\ln \left[ \frac{G(1-z)}{G(1+z)} \right] = \int_0^z \pi z \cot(\pi z) dz - z \ln(2\pi) \quad (7)$$

and has the special values

$$G\left(\frac{1}{2}\right) = A^{-3/2} \pi^{-1/4} e^{1/8} 2^{1/24} \quad (8)$$

$$G(1) = 1, \quad (9)$$

where

$$A = \exp \left[ -\frac{\zeta'(2)}{2\pi^2} + \frac{\ln(2\pi)}{12} + \frac{\gamma}{2} \right] = 1.28242713 \dots \quad (10)$$

The  $G$ -function can arise in spectral functions in mathematical physics (Voros 1987).

An unrelated pair of functions are denoted  $g_n$  and  $G_n$  and are known as RAMANUJAN  $g$ - AND  $G$ -FUNCTIONS.

see also EULER-MASCHERONI CONSTANT, GLAISHER-KINKELIN CONSTANT,  $K$ -FUNCTION, MEIJER'S  $G$ -FUNCTION, RAMANUJAN  $g$ - AND  $G$ -FUNCTIONS, SUPERFACTORIAL

## G-Number

see EISENSTEIN INTEGER

## G-Space

A  $G$ -space is a special type of HAUSDORFF SPACE. Consider a point  $x$  and a HOMEOMORPHISM of an open NEIGHBORHOOD  $V$  of  $x$  onto an OPEN SET of  $\mathbb{R}^n$ . Then a space is a  $G$ -space if, for any two such NEIGHBORHOODS  $V'$  and  $V''$ , the images of  $V' \cup V''$  under the different HOMEOMORPHISMS are ISOMETRIC. If  $n = 2$ , the HOMEOMORPHISMS need only be conformal (but not necessarily orientation-preserving).

see also GREEN SPACE

**Gabriel's Horn**

The SURFACE OF REVOLUTION of the function  $y = 1/x$  about the  $x$ -axis for  $x \geq 1$ . It has FINITE VOLUME

$$\begin{aligned} V &= \int_1^{\infty} \pi y^2 dx = \pi \int_1^{\infty} \frac{dx}{x^2} \\ &= \pi \left[ -\frac{1}{x} \right]_1^{\infty} = \pi[0 - (-1)] = \pi, \end{aligned}$$

but INFINITE SURFACE AREA, since

$$\begin{aligned} S &= \int_1^{\infty} 2\pi y \sqrt{1 + y'^2} dx \\ &> 2\pi \int_1^{\infty} y dx = 2\pi \int_1^{\infty} \frac{dx}{x} = 2\pi [\ln x]_1^{\infty} \\ &= 2\pi [\ln \infty - 0] = \infty. \end{aligned}$$

This leads to the paradoxical consequence that while Gabriel's horn can be filled up with  $\pi$  cubic units of paint, an INFINITE number of square units of paint are needed to cover its surface!

see also FUNNEL, PSEUDOSPHERE

**Gabriel's Staircase**

The SUM

$$\sum_{k=1}^{\infty} kr^k = \frac{r}{(1-r)^2},$$

valid for  $0 < r < 1$ .

**Gadget**

A term of endearment used by ALGEBRAIC TOPOLOGISTS when talking about their favorite power tools such as ABELIAN GROUPS, BUNDLES, HOMOLOGY GROUPS, HOMOTOPY GROUPS,  $k$ -THEORY, MORSE THEORY, OBSTRUCTIONS, stable homotopy theory, VECTOR SPACES, etc.

see also ABELIAN GROUP, ALGEBRAIC TOPOLOGY, BUNDLE, FREE, HOMOLOGY GROUP, HOMOTOPY GROUP,  $k$ -THEORY, OBSTRUCTION, MORSE THEORY, VECTOR SPACE

**Gale-Ryser Theorem**

Let  $p$  and  $q$  be PARTITIONS of a POSITIVE INTEGER, then there exists a  $(0,1)$ -matrix  $A$  such that  $c(A) = p$ ,  $r(A) = q$  IFF  $q$  is dominated by  $p^*$ .

**Galilean Transformation**

A transformation from one reference frame to another moving with a constant VELOCITY  $v$  with respect to the first for classical motion. However, special relativity shows that the transformation must be modified to the LORENTZ TRANSFORMATION for relativistic motion. The forward Galilean transformation is

$$\begin{bmatrix} t' \\ x' \\ y' \\ z' \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -v & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} t \\ x \\ y \\ z \end{bmatrix},$$

and the inverse transformation is

$$\begin{bmatrix} t \\ x \\ y \\ z \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ v & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} t' \\ x' \\ y' \\ z' \end{bmatrix}.$$

see also LORENTZ TRANSFORMATION

**Gall's Stereographic Projection**

A CYLINDRICAL PROJECTION which projects the equator onto a tangent cylinder which intersects the globe at  $\pm 45^\circ$ . The transformation equations are

$$\begin{aligned} x &= \lambda \\ y &= \tan\left(\frac{1}{2}\phi\right), \end{aligned}$$

where  $\lambda$  is the LONGITUDE and  $\phi$  the LATITUDE.

see also STEREOGRAPHIC PROJECTION

**Gallows**

Schroeder (1991) calls the CEILING FUNCTION symbols  $\lceil$  and  $\rceil$  the "gallows" because of their similarity in appearance to the structure used for hangings.

see also CEILING FUNCTION

**References**

- Schroeder, M. *Fractals, Chaos, Power Laws: Minutes from an Infinite Paradise*. New York: W. H. Freeman, p. 57, 1991.

**Gallucci's Theorem**

If three SKEW LINES all meet three other SKEW LINES, any TRANSVERSAL to the first set of three meets any TRANSVERSAL to the second set of three.

see also SKEW LINES, TRANSVERSAL LINE

**Galois Extension Field**

The splitting FIELD for a separable POLYNOMIAL over a FINITE FIELD  $K$ , where  $L$  is a FIELD EXTENSION of  $K$ .

**Galois Field**

see FINITE FIELD

**Galois Group**

Let  $L$  be a FIELD EXTENSION of  $K$ , denoted  $L/K$ , and let  $G$  be the set of AUTOMORPHISMS of  $L/K$ , that is, the set of AUTOMORPHISMS  $\sigma$  of  $L$  such that  $\sigma(x) = x$  for every  $x \in K$ , so that  $K$  is fixed. Then  $G$  is a GROUP of transformations of  $L$ , called the Galois group of  $L/K$ .

The Galois group of  $(\mathbb{C}/\mathbb{R})$  consists of the IDENTITY ELEMENT and COMPLEX CONJUGATION. These functions both take a given REAL to the same real.

see also ABHYANKAR'S CONJECTURE, FINITE GROUP, GROUP

**References**

Jacobson, N. *Basic Algebra I*, 2nd ed. New York: W. H. Freeman, p. 234, 1985.

**Galois Imaginary**

A mathematical object invented to solve irreducible CONGRUENCES of the form

$$F(x) \equiv 0 \pmod{p},$$

where  $p$  is PRIME.

**Galois's Theorem**

An algebraic equation is algebraically solvable IFF its GROUP is SOLVABLE. In order that an irreducible equation of PRIME degree be solvable by radicals, it is NECESSARY and SUFFICIENT that all its ROOTS be rational functions of two ROOTS.

see also ABEL'S IMPOSSIBILITY THEOREM, SOLVABLE GROUP

**Galois Theory**

If there exists a ONE-TO-ONE correspondence between two SUBGROUPS and SUBFIELDS such that

$$\begin{aligned} G(E(G')) &= G' \\ E(G(E')) &= E', \end{aligned}$$

then  $E$  is said to have a Galois theory.

**Galoisian**

An algebraic extension  $E$  of  $F$  for which every IRREDUCIBLE POLYNOMIAL in  $F$  which has a single ROOT in  $E$  has all its ROOTS in  $E$  is said to be Galoisian. Galoisian extensions are also called algebraically normal.

**Gambler's Ruin**

Let two players each have a finite number of pennies (say,  $n_1$  for player one and  $n_2$  for player two). Now, flip one of the pennies (from either player), with each player having 50% probability of winning, and give the penny to the winner. If the process is repeated indefinitely, the probability that one or the other player will eventually lose all his pennies is unity. However, the chances that the individual players will be rendered penniless are

$$\begin{aligned} P_1 &= \frac{n_1}{n_1 + n_2} \\ P_2 &= \frac{n_2}{n_1 + n_2}. \end{aligned}$$

**Game**

A game is defined as a conflict involving gains and losses between two or more opponents who follow formal rules. The study of games belongs to a branch of mathematics known as GAME THEORY.

see also GAME THEORY

**Game Expectation**

Let the elements in a PAYOFF MATRIX be denoted  $a_{ij}$ , where the  $i$ s are player A's STRATEGIES and the  $j$ s are player B's STRATEGIES. Player A can get at least

$$\min_{j \leq n} a_{ij} \tag{1}$$

for STRATEGY  $i$ . Player B can force player A to get no more than  $\max_{j \leq m} a_{ij}$  for a STRATEGY  $j$ . The best STRATEGY for player A is therefore

$$\min_{i \leq m} \min_{j \leq n} a_{ij}, \tag{2}$$

and the best STRATEGY for player B is

$$\min_{j \leq n} \max_{i \leq m} a_{ij}. \tag{3}$$

In general,

$$\min_{i \leq m} \min_{j \leq n} a_{ij} \leq \min_{j \leq n} \max_{i \leq m} a_{ij}. \quad (4)$$

Equality holds only if a SADDLE POINT is present, in which case the quantity is called the VALUE of the game.

see LIFE

## Game Matrix

see PAYOFF MATRIX

## Game Theory

A branch of MATHEMATICS and LOGIC which deals with the analysis of GAMES (i.e., situations in which parties are involved in situations where their interests conflict). In addition to the mathematical elegance and complete "solution" which is possible for simple games, the principles of game theory also find applications to complicated games such as cards, checkers, and chess, as well as real-world problems as diverse as economics, property division, politics, and warfare.

## Gamma Distribution

A general type of statistical DISTRIBUTION which is related to the BETA DISTRIBUTION and arises naturally in processes for which the waiting times between POISSON DISTRIBUTED events are relevant. Gamma distributions have two free parameters, labeled  $\alpha$  and  $\theta$ , a few of which are illustrated above.

Given a POISSON DISTRIBUTION with a rate of change  $\lambda$ , the DISTRIBUTION FUNCTION  $D(x)$  giving the waiting times until the  $h$ th change is

$$\begin{aligned} D(x) &= P(X \leq x) = 1 - P(X > x) \\ &= 1 - \sum_{k=0}^{h-1} \frac{(\lambda x)^k e^{-\lambda x}}{k!} \\ &= 1 - e^{-\lambda x} \sum_{k=0}^{h-1} \frac{(\lambda x)^k}{k!} \end{aligned} \quad (1)$$

for  $x \geq 0$ . The probability function  $P(x)$  is then obtained by differentiating  $D(x)$ ,

$$\begin{aligned} P(x) &= D'(x) \\ &= \lambda e^{-\lambda x} \sum_{k=0}^{h-1} \frac{(\lambda x)^k}{k!} - e^{-\lambda x} \sum_{k=0}^{h-1} \frac{k(\lambda x)^{k-1} \lambda}{k!} \\ &= \lambda e^{-\lambda x} + \lambda e^{-\lambda x} \sum_{k=1}^{h-1} \frac{(\lambda x)^k}{k!} - e^{-\lambda x} \sum_{k=1}^{h-1} \frac{k(\lambda x)^{k-1} \lambda}{k!} \\ &= \lambda e^{-\lambda x} - \lambda e^{-\lambda x} \sum_{k=1}^{h-1} \left[ \frac{k(\lambda x)^{k-1}}{k!} - \frac{(\lambda x)^k}{k!} \right] \\ &= \lambda e^{-\lambda x} \left\{ 1 - \sum_{k=1}^{h-1} \left[ \frac{(\lambda x)^{k-1}}{(k-1)!} - \frac{(\lambda x)^k}{k!} \right] \right\} \\ &= \lambda e^{-\lambda x} \left\{ 1 - \left[ 1 - \frac{(\lambda x)^{h-1}}{(h-1)!} \right] \right\} = \frac{\lambda(\lambda x)^{h-1}}{(h-1)!} e^{-\lambda x}. \end{aligned} \quad (2)$$

Now let  $\alpha \equiv h$  and define  $\theta \equiv 1/\lambda$  to be the time between changes. Then the above equation can be written

$$P(x) = \begin{cases} \frac{x^{\alpha-1} e^{-x/\theta}}{\Gamma(\alpha)\theta^\alpha} & 0 \leq x < \infty \\ 0 & x < 0. \end{cases} \quad (3)$$

The CHARACTERISTIC FUNCTION describing this distribution is

$$\phi(t) = (1 - it)^{-\alpha}, \quad (4)$$

and the MOMENT-GENERATING FUNCTION is

$$\begin{aligned} M(t) &= \int_0^\infty \frac{e^{tx} x^{\alpha-1} e^{-x/\theta} dx}{\Gamma(\alpha)\theta^\alpha} \\ &= \int_0^\infty \frac{x^{\alpha-1} e^{-(1-\theta t)x/\theta} dx}{\Gamma(\alpha)\theta^\alpha}. \end{aligned} \quad (5)$$

In order to find the MOMENTS of the distribution, let

$$y \equiv \frac{(1 - \theta t)x}{\theta} \quad (6)$$

$$dy = \frac{1 - \theta t}{\theta} dx, \quad (7)$$

so

$$\begin{aligned} M(t) &= \int_0^\infty \left( \frac{\theta y}{1 - \theta t} \right)^{\alpha-1} \frac{e^{-y}}{\Gamma(\alpha)\theta^\alpha} \frac{\theta dy}{1 - \theta t} \\ &= \frac{1}{(1 - \theta t)^\alpha \Gamma(\alpha)} \int_0^\infty y^{\alpha-1} e^{-y} dy \\ &= \frac{1}{(1 - \theta t)^\alpha}, \end{aligned} \quad (8)$$

and the logarithmic Moment-Generating function is

$$R(t) \equiv \ln M(t) = -\alpha \ln(1 - \theta t) \quad (9)$$

$$R'(t) = \frac{\alpha\theta}{1 - \theta t} \quad (10)$$

$$R''(t) = \frac{\alpha\theta^2}{(1 - \theta t)^2}. \quad (11)$$

The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are then

$$\mu = R'(0) = \alpha\theta \quad (12)$$

$$\sigma^2 = R''(0) = \alpha\theta^2 \quad (13)$$

$$\gamma_1 = \frac{2}{\sqrt{\alpha}} \quad (14)$$

$$\gamma_2 = \frac{6}{\alpha}. \quad (15)$$

The gamma distribution is closely related to other statistical distributions. If  $X_1, X_2, \dots, X_n$  are independent

random variates with a gamma distribution having parameters  $(\alpha_1, \theta), (\alpha_2, \theta), \dots, (\alpha_n, \theta)$ , then  $\sum_{i=1}^n X_i$  is distributed as gamma with parameters

$$\alpha = \sum_{i=1}^n \alpha_i \quad (16)$$

$$\theta = \theta. \quad (17)$$

Also, if  $X_1$  and  $X_2$  are independent random variates with a gamma distribution having parameters  $(\alpha_1, \theta)$  and  $(\alpha_2, \theta)$ , then  $X_1/(X_1 + X_2)$  is a BETA DISTRIBUTION variate with parameters  $(\alpha_1, \alpha_2)$ . Both can be derived as follows.

$$P(x, y) = \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{x_1 + x_2} x_1^{\alpha_1-1} x_2^{\alpha_2-1}. \quad (18)$$

Let

$$u = x_1 + x_2 \quad x_1 = uv \quad (19)$$

$$v = \frac{x_1}{x_1 + x_2} \quad x_2 = u(1 - v), \quad (20)$$

then the JACOBIAN is

$$J \left( \frac{x_1, x_2}{u, v} \right) = \begin{vmatrix} v & u \\ 1 - v & -u \end{vmatrix} = -u, \quad (21)$$

so

$$g(u, v) du dv = f(x, y) dx dy = f(x, y) u du dv. \quad (22)$$

$$\begin{aligned} g(u, v) &= \frac{u}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u} (uv)^{\alpha_1-1} u^{\alpha_2-1} (1 - v)^{\alpha_2-1} \\ &= \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u} u^{\alpha_1+\alpha_2-1} v^{\alpha_1-1} (1 - v)^{\alpha_2-1}. \end{aligned} \quad (23)$$

The sum  $X_1 + X_2$  therefore has the distribution

$$f(u) = f(x_1 + x_2) = \int_0^1 g(u, v) dv = \frac{e^{-u} u^{\alpha_1+\alpha_2-1}}{\Gamma(\alpha_1 + \alpha_2)}, \quad (24)$$

which is a gamma distribution, and the ratio  $X_1/(X_1 + X_2)$  has the distribution

$$\begin{aligned} h(v) &= h \left( \frac{x_1}{x_1 + x_2} \right) = \int_0^\infty g(u, v) du \\ &= \frac{v^{\alpha_1-1} (1 - v)^{\alpha_2-1}}{B(\alpha_1, \alpha_2)}, \end{aligned} \quad (25)$$

where  $B$  is the BETA FUNCTION, which is a BETA DISTRIBUTION.

If  $X$  and  $Y$  are gamma variates with parameters  $\alpha_1$  and  $\alpha_2$ , the  $X/Y$  is a variate with a BETA PRIME DISTRIBUTION with parameters  $\alpha_1$  and  $\alpha_2$ . Let

$$u = x + y \quad v = \frac{x}{y}, \quad (26)$$

then the JACOBIAN is

$$J\left(\frac{u}{x}, \frac{v}{y}\right) = \left| \frac{1}{\frac{x}{y}} - \frac{1}{\frac{x}{y^2}} \right| = -\frac{x+y}{y^2} = -\frac{(1+v)^2}{u}, \quad (27)$$

so

$$dx dy = \frac{u}{(1+v)^2} du dv \quad (28)$$

$$\begin{aligned} g(u, v) &= \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u} \left( \frac{uv}{1+v} \right)^{\alpha_1-1} \\ &\quad \left( \frac{u}{1+v} \right)^{\alpha_2-1} \frac{u}{(1+v)^2} \\ &= \frac{1}{\Gamma(\alpha_1)\Gamma(\alpha_2)} e^{-u} u^{\alpha_1+\alpha_2-1} v^{\alpha_2-1} (1+v)^{-\alpha_1-\alpha_2}. \end{aligned} \quad (29)$$

The ratio  $X/Y$  therefore has the distribution

$$h(v) = \int_0^\infty g(u, v) du = \frac{v^{\alpha_1-1} (1+v)^{-\alpha_1-\alpha_2}}{B(\alpha_1, \alpha_2)}, \quad (30)$$

which is a BETA PRIME DISTRIBUTION with parameters  $(\alpha_1, \alpha_2)$ .

The "standard form" of the gamma distribution is given by letting  $y \equiv x/\theta$ , so  $dy = dx/\theta$  and

$$\begin{aligned} P(y) dy &= \frac{x^{\alpha-1} e^{-x/\theta}}{\Gamma(\alpha)\theta^\alpha} dx = \frac{(\theta y)^{\alpha-1} e^{-y}}{\Gamma(\alpha)\theta^\alpha} (\theta dy) \\ &= \frac{y^{\alpha-1} e^{-y}}{\Gamma(\alpha)} dy, \end{aligned} \quad (31)$$

so the MOMENTS about 0 are

$$\nu_r = \frac{1}{\Gamma(\alpha)} \int_0^\infty e^{-x} x^{\alpha-1+r} dx = \frac{\Gamma(\alpha+r)}{\Gamma(\alpha)} = (\alpha)_r, \quad (32)$$

where  $(\alpha)_r$  is the POCHHAMMER SYMBOL. The MOMENTS about  $\mu = \mu_1$  are then

$$\mu_1 = \alpha \quad (33)$$

$$\mu_2 = \alpha \quad (34)$$

$$\mu_3 = 2\alpha \quad (35)$$

$$\mu_4 = 3\alpha^2 + 6\alpha. \quad (36)$$

The MOMENT-GENERATING FUNCTION is

$$M(t) = \frac{1}{(1-t)^\alpha}, \quad (37)$$

and the CUMULANT-GENERATING FUNCTION is

$$K(t) = \alpha \ln(1-t) = \alpha \left( t + \frac{1}{2}t^2 + \frac{1}{3}t^3 + \dots \right), \quad (38)$$

so the CUMULANTS are

$$\kappa_r = \alpha \Gamma(r). \quad (39)$$

If  $x$  is a NORMAL variate with MEAN  $\mu$  and STANDARD DEVIATION  $\sigma$ , then

$$y \equiv \frac{(x-\mu)^2}{2\sigma^2} \quad (40)$$

is a standard gamma variate with parameter  $\alpha = 1/2$ .

#### Gamma Function

The complete gamma function is defined to be an extension of the FACTORIAL to COMPLEX and REAL NUMBER arguments. It is ANALYTIC everywhere except at  $z = 0, -1, -2, \dots$ . It can be defined as a DEFINITE INTEGRAL for  $\Re[z] > 0$  (Euler's integral form)

$$\Gamma(z) \equiv \int_0^\infty t^{z-1} e^{-t} dt \quad (1)$$

$$= 2 \int_0^\infty e^{-t^2} t^{2z-1} dt, \quad (2)$$

or

$$\Gamma(z) \equiv \int_0^1 \left[ \ln\left(\frac{1}{t}\right) \right]^{z-1} dt. \quad (3)$$

INTEGRATING (1) by parts for a REAL argument, it can be seen that

$$\begin{aligned} \Gamma(x) &= \int_0^\infty t^{x-1} e^{-t} dt \\ &= [-t^{x-1} e^{-t}]_0^\infty + \int_0^\infty (x-1) t^{x-2} e^{-t} dt \\ &= (x-1) \int_0^\infty t^{x-2} e^{-t} dt = (x-1) \Gamma(x-1). \end{aligned} \quad (4)$$

If  $x$  is an INTEGER  $n = 1, 2, 3, \dots$  then

$$\begin{aligned}\Gamma(n) &= (n-1)\Gamma(n-1) = (n-1)(n-2)\Gamma(n-2) \\ &= (n-1)(n-2)\cdots 1 = (n-1)!,\end{aligned}\quad (5)$$

so the gamma function reduces to the FACTORIAL for a POSITIVE INTEGER argument.

BINET'S FORMULA is

$$\ln \Gamma(a) = (a - \tfrac{1}{2}) \ln a - a + \tfrac{1}{2} \ln(2\pi) + 2 \int_0^\infty \frac{\tan(\frac{z}{a})}{e^{2\pi z} - 1} dz \quad (6)$$

for  $\Re[a] > 0$  (Whittaker and Watson 1990, p. 251). The gamma function can also be defined by an INFINITE PRODUCT form (Weierstraß Form)

$$\Gamma(z) \equiv \left[ z e^{\gamma z} \prod_{r=1}^{\infty} \left( 1 + \frac{z}{r} \right) e^{-z/r} \right]^{-1}, \quad (7)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT. This can be written

$$\Gamma(z) = \frac{1}{z} \exp \left[ \sum_{k=1}^{\infty} \frac{(-1)^k s_k}{k} x^k \right], \quad (8)$$

where

$$s_1 \equiv \gamma \quad (9)$$

$$s_k \equiv \zeta(k) \quad (10)$$

for  $k \geq 2$ , where  $\zeta$  is the RIEMANN ZETA FUNCTION (Finch). Taking the logarithm of both sides of (7),

$$-\ln[\Gamma(z)] = \ln z + \gamma z + \sum_{n=1}^{\infty} \left[ \ln \left( 1 + \frac{z}{n} \right) - \frac{z}{n} \right]. \quad (11)$$

Differentiating,

$$\begin{aligned}-\frac{\Gamma'(z)}{\Gamma(z)} &= \frac{1}{z} + \gamma + \sum_{n=1}^{\infty} \left( \frac{\frac{1}{n}}{1 + \frac{z}{n}} - \frac{1}{n} \right) \\ &= \frac{1}{z} + \gamma + \sum_{n=1}^{\infty} \left( \frac{1}{n+z} - \frac{1}{n} \right)\end{aligned}\quad (12)$$

$$\Gamma'(z) = -\Gamma(z) \left[ \frac{1}{z} + \gamma + \sum_{n=1}^{\infty} \left( \frac{1}{n+z} - \frac{1}{n} \right) \right] \quad (13)$$

$$\equiv \Gamma(z) \Psi(z) = \Gamma(z) \psi_0(z) \quad (14)$$

$$\begin{aligned}\Gamma'(1) &= -\Gamma(1) - \left\{ 1 + \gamma + \left[ \left( \frac{1}{2} - 1 \right) + \left( \frac{1}{3} - \frac{1}{2} \right) \right. \right. \\ &\quad \left. \left. + \dots + \left( \frac{1}{n+1} - \frac{1}{n} \right) + \dots \right] \right\} \\ &= -(1 + \gamma - 1) = -\gamma\end{aligned}\quad (15)$$

$$\begin{aligned}\Gamma'(n) &= -\Gamma(n) \left\{ \frac{1}{n} + \gamma + \left[ \left( \frac{1}{1+n} - 1 \right) + \left( \frac{1}{2+n} - \frac{1}{2} \right) \right. \right. \\ &\quad \left. \left. + \left( \frac{1}{3+n} - \frac{1}{3} \right) + \dots \right] \right\} \\ &= -(n-1)! \left( \frac{1}{n} + \gamma - \sum_{k=1}^n \frac{1}{k} \right),\end{aligned}\quad (16)$$

where  $\Psi(z)$  is the DIGAMMA FUNCTION and  $\psi_0(z)$  is the POLYGAMMA FUNCTION.  $n$ th derivatives are given in terms of the POLYGAMMA FUNCTIONS  $\psi_n, \psi_{n-1}, \dots, \psi_0$ .

The minimum value  $x_0$  of  $\Gamma(x)$  for REAL POSITIVE  $x = x_0$  is achieved when

$$\Gamma'(x_0) = \Gamma(x_0) \psi_0(x_0) = 0 \quad (17)$$

$$\psi_0(x_0) = 0, \quad (18)$$

This can be solved numerically to give  $x_0 = 1.46163\dots$  (Sloane's A030169), which has CONTINUED FRACTION  $[1, 2, 6, 63, 135, 1, 1, 1, 1, 4, 1, 38, \dots]$  (Sloane's A030170). At  $x_0$ ,  $\Gamma(x_0)$  achieves the value  $0.8856031944\dots$  (Sloane's A030171), which has CONTINUED FRACTION  $[0, 1, 7, 1, 2, 1, 6, 1, 1, \dots]$  (Sloane's A030172).

The Euler limit form is

$$\begin{aligned}\frac{1}{\Gamma(z)} &= z \left[ \lim_{m \rightarrow \infty} e^{(1+1/2+\dots+1/m - \ln m)z} \right] \\ &\quad \times \left[ \lim_{m \rightarrow \infty} \prod_{n=1}^m \left\{ \left( 1 + \frac{z}{n} \right) e^{-z/n} \right\} \right] \\ &= \frac{1}{z} \prod_{n=1}^{\infty} \left[ \left( 1 + \frac{1}{n} \right)^z \left( 1 + \frac{z}{n} \right)^{-1} \right],\end{aligned}\quad (19)$$

so

$$\Gamma(z) \equiv \lim_{n \rightarrow \infty} \frac{1 \cdot 2 \cdot 3 \cdots n}{z(z+1)(z+2)\cdots(z+n)} n^z. \quad (20)$$

The LANZOS APPROXIMATION for  $z > 0$  is

$$\begin{aligned}\Gamma(z+1) &= (z + \gamma + \tfrac{1}{2})^{z+1/2} e^{z+\gamma+1/2} \sqrt{2\pi} \\ &\quad \times \left[ c_0 + \frac{c_1}{z+1} + \frac{c_2}{z+2} + \dots + \frac{c_n}{z+n} + \epsilon \right].\end{aligned}\quad (21)$$

The complete gamma function  $\Gamma(x)$  can be generalized to the incomplete gamma function  $\Gamma(x, a)$  such that  $\Gamma(x) = \Gamma(x, 0)$ . The gamma function satisfies the recurrence relations

$$\Gamma(1+z) = z\Gamma(z) \quad (22)$$

$$\Gamma(1-z) = -z\Gamma(-z). \quad (23)$$

Additional identities are

$$\Gamma(x)\Gamma(-x) = -\frac{\pi}{x \sin(\pi x)} \quad (24)$$

$$\Gamma(x)\Gamma(1-x) = \frac{\pi}{\sin(\pi x)} \quad (25)$$

$$\begin{aligned}\ln[\Gamma(x + iy + 1)] &= \ln(x^2 + y^2) + i \tan^{-1} \left( \frac{y}{x} \right) \\ &\quad + \ln[\Gamma(x + iy)]\end{aligned}\quad (26)$$

$$|(ix)!|^2 = \frac{\pi x}{\sinh(\pi x)} \quad (27)$$

$$|(n + ix)!| = \sqrt{\frac{\pi x}{\sinh(\pi x)}} \prod_{s=1}^n \sqrt{s^2 + x^2}. \quad (28)$$

For integral arguments, the first few values are 1, 1, 2, 6, 24, 120, 720, 5040, 40320, 362880, ... (Sloane's A000142). For half integral arguments,

$$\Gamma(\tfrac{1}{2}) = \sqrt{\pi} \quad (29)$$

$$\Gamma(\tfrac{3}{2}) = \tfrac{1}{2}\sqrt{\pi} \quad (30)$$

$$\Gamma(\tfrac{5}{2}) = \tfrac{3}{4}\sqrt{\pi}. \quad (31)$$

In general, for  $m$  a POSITIVE INTEGER  $m = 1, 2, \dots$

$$\begin{aligned} \Gamma(\tfrac{1}{2} + m) &= \frac{1 \cdot 3 \cdot 5 \cdots (2m-1)}{2^m} \sqrt{\pi} \\ &= \frac{(2m-1)!!}{2^m} \sqrt{\pi} \end{aligned} \quad (32)$$

$$\begin{aligned} \Gamma(\tfrac{1}{2} - m) &= \frac{(-1)^m 2^m}{1 \cdot 3 \cdot 5 \cdots (2m-1)} \sqrt{\pi} \\ &= \frac{(-1)^m 2^m}{(2m-1)!!} \sqrt{\pi}. \end{aligned} \quad (33)$$

For  $\Re[x] = -\tfrac{1}{2}$ ,

$$|(-\tfrac{1}{2} + iy)!|^2 = \frac{\pi}{\cosh(\pi y)}. \quad (34)$$

Gamma functions of argument  $2z$  can be expressed using the LEGENDRE DUPLICATION FORMULA

$$\Gamma(2z) = (2\pi)^{-1/2} 2^{2z-1/2} \Gamma(z) \Gamma(z + \tfrac{1}{2}). \quad (35)$$

Gamma functions of argument  $3z$  can be expressed using a triplication FORMULA

$$\Gamma(3z) = (2\pi)^{-1} 3^{3z-1/2} \Gamma(z) \Gamma(z + \tfrac{1}{3}) \Gamma(z + \tfrac{2}{3}). \quad (36)$$

The general result is the GAUSS MULTIPLICATION FORMULA

$$\Gamma(z) \Gamma(z + \tfrac{1}{n}) \cdots \Gamma(z + \tfrac{n-1}{n}) = (2\pi)^{(n-1)/2} n^{1/2-nz} \Gamma(nz). \quad (37)$$

The gamma function is also related to the RIEMANN ZETA FUNCTION  $\zeta$  by

$$\Gamma\left(\frac{s}{2}\right) \pi^{-s/2} \zeta(s) = \Gamma\left(\frac{1-s}{2}\right) \pi^{-(1-s)/2} \zeta(1-s). \quad (38)$$

Borwein and Zucker (1992) give a variety of identities relating gamma functions to square roots and ELLIPTIC INTEGRAL SINGULAR VALUES  $k_n$ , i.e., MODULI  $k_n$  such that

$$\frac{K'(k_n)}{K(k_n)} = \sqrt{n}, \quad (39)$$

where  $K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and  $K'(k) = K(k') = K(\sqrt{1-k^2})$  is the complementary integral.

$$\Gamma(\tfrac{1}{3}) = 2^{7/9} 3^{-1/12} \pi^{1/3} [K(k_3)]^{1/3} \quad (40)$$

$$\Gamma(\tfrac{1}{4}) = 2\pi^{1/4} [K(k_1)]^{1/2} \quad (41)$$

$$\Gamma(\tfrac{1}{6}) = 2^{-1/3} 3^{1/2} \pi^{-1/2} [\Gamma(\tfrac{1}{3})]^2 \quad (42)$$

$$\Gamma(\tfrac{1}{8}) \Gamma(\tfrac{3}{8}) = (\sqrt{2} - 1)^{1/2} 2^{13/4} \pi^{1/2} K(k_2) \quad (43)$$

$$\frac{\Gamma(\tfrac{1}{8})}{\Gamma(\tfrac{3}{8})} = 2(\sqrt{2} + 1)^{1/2} \pi^{-1/4} [K(k_1)]^{1/2} \quad (44)$$

$$\Gamma(\tfrac{1}{12}) = 2^{-1/4} 3^{3/8} (\sqrt{3} + 1)^{1/2} \pi^{-1/2} \Gamma(\tfrac{1}{4}) \Gamma(\tfrac{1}{3}) \quad (45)$$

$$\Gamma(\tfrac{5}{12}) = 2^{1/4} 3^{-1/8} (\sqrt{3} - 1)^{1/2} \pi^{1/2} \frac{\Gamma(\tfrac{1}{4})}{\Gamma(\tfrac{1}{3})} \quad (46)$$

$$\frac{\Gamma(\tfrac{1}{24}) \Gamma(\tfrac{11}{24})}{\Gamma(\tfrac{5}{24}) \Gamma(\tfrac{7}{24})} = \sqrt{3} \sqrt{2 + \sqrt{3}} \quad (47)$$

$$\frac{\Gamma(\tfrac{1}{24}) \Gamma(\tfrac{5}{24})}{\Gamma(\tfrac{7}{24}) \Gamma(\tfrac{11}{24})} = 4 \cdot 3^{1/4} (\sqrt{3} + \sqrt{2}) \pi^{-1/2} K(k_1) \quad (48)$$

$$\frac{\Gamma(\tfrac{1}{24}) \Gamma(\tfrac{7}{24})}{\Gamma(\tfrac{5}{24}) \Gamma(\tfrac{11}{24})} = 2^{25/18} 3^{1/3} (\sqrt{2} + 1) \pi^{-1/3} [K(k_3)]^{2/3} \quad (49)$$

$$\begin{aligned} \Gamma(\tfrac{1}{24}) \Gamma(\tfrac{5}{24}) \Gamma(\tfrac{7}{24}) \Gamma(\tfrac{11}{24}) \\ = 384(\sqrt{2} + 1)(\sqrt{3} - \sqrt{2})(2 - \sqrt{3}) \pi [K(k_6)]^2 \end{aligned} \quad (50)$$

$$\Gamma(\tfrac{1}{10}) = 2^{-7/10} 5^{1/4} (\sqrt{5} + 1)^{1/2} \pi^{-1/2} \Gamma(\tfrac{1}{5}) \Gamma(\tfrac{2}{5}) \quad (51)$$

$$\Gamma(\tfrac{3}{10}) = 2^{-3/5} (\sqrt{5} - 1) \pi^{1/2} \frac{\Gamma(\tfrac{1}{5})}{\Gamma(\tfrac{2}{5})} \quad (52)$$

$$\frac{\Gamma(\tfrac{1}{15}) \Gamma(\tfrac{4}{15}) \Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{2}{15})} = 2 \cdot 3^{1/2} 5^{1/6} \sin(\tfrac{2}{15} \pi) [\Gamma(\tfrac{1}{3})]^2 \quad (53)$$

$$\begin{aligned} \frac{\Gamma(\tfrac{1}{15}) \Gamma(\tfrac{2}{15}) \Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{4}{15})} \\ = 2^2 \cdot 3^{2/5} \sin(\tfrac{1}{5} \pi) \sin(\tfrac{4}{15} \pi) [\Gamma(\tfrac{1}{5})]^2 \end{aligned} \quad (54)$$

$$\begin{aligned} \frac{\Gamma(\tfrac{2}{15}) \Gamma(\tfrac{4}{15}) \Gamma(\tfrac{7}{15})}{\Gamma(\tfrac{1}{15})} \\ = \frac{2^{-3/2} 3^{-1/5} 5^{1/4} (\sqrt{5} - 1)^{1/2} [\Gamma(\tfrac{2}{5})]^2}{\sin(\tfrac{4}{15} \pi)} \end{aligned} \quad (55)$$

$$\frac{\Gamma(\tfrac{1}{15}) \Gamma(\tfrac{2}{15}) \Gamma(\tfrac{4}{15})}{\Gamma(\tfrac{7}{15})} = 60(\sqrt{5} - 1) \sin(\tfrac{7}{15} \pi) [K(k_{15})]^2 \quad (56)$$

$$\frac{\Gamma(\tfrac{1}{20}) \Gamma(\tfrac{9}{20})}{\Gamma(\tfrac{3}{20}) \Gamma(\tfrac{7}{20})} = 2^{-1} 5^{1/4} (\sqrt{5} + 1) \quad (57)$$

$$\begin{aligned} \frac{\Gamma(\tfrac{1}{20}) \Gamma(\tfrac{3}{20})}{\Gamma(\tfrac{7}{20}) \Gamma(\tfrac{9}{20})} \\ = 2^{4/5} (10 - 2\sqrt{5})^{1/2} \pi^{-1} \sin(\tfrac{7}{20} \pi) \sin(\tfrac{9}{20} \pi) [\Gamma(\tfrac{1}{5})]^2 \end{aligned} \quad (58)$$

$$\frac{\Gamma(\tfrac{1}{20}) \Gamma(\tfrac{7}{20})}{\Gamma(\tfrac{3}{20}) \Gamma(\tfrac{9}{20})}$$

$$= 2^{3/5} (10 + 2\sqrt{5})^{1/2} \pi^{-1} \sin(\frac{3}{20}\pi) \sin(\frac{9}{20}\pi) [\Gamma(\frac{2}{5})]^2 \quad (59)$$

$$\Gamma(\frac{1}{20})\Gamma(\frac{3}{20})\Gamma(\frac{7}{20})\Gamma(\frac{9}{20}) = 160(\sqrt{5} - 2)^{1/2} \pi [K(k_5)]^2. \quad (60)$$

A few curious identities include

$$\prod_{n=1}^8 \Gamma(\frac{1}{3}n) = \frac{640}{3^6} \left( \frac{\pi}{\sqrt{3}} \right)^3 \quad (61)$$

$$\frac{[\Gamma(\frac{1}{4})]^4}{16\pi^2} = \frac{3^2}{3^2-1} \frac{5^2-1}{5^2} \frac{7^2}{7^2-1} \cdots \quad (62)$$

$$\frac{\Gamma'(1)}{\Gamma(1)} - \frac{\Gamma'(\frac{1}{2})}{\Gamma(\frac{1}{2})} = 2 \ln 2 \quad (63)$$

(Magnus and Oberhettinger 1949, p. 1). Ramanujan also gave a number of fascinating identities:

$$\frac{\Gamma^2(n+1)}{\Gamma(n+xi+1)\Gamma(n-xi+1)} = \prod_{k=1}^{\infty} \left[ 1 + \frac{x^2}{(n+k)^2} \right] \quad (64)$$

$$\phi(m, n)\phi(n, m) = \frac{\Gamma^3(m+1)\Gamma^3(n+1)}{\Gamma(2m+n+1)\Gamma(2n+m+1)} \times \frac{\cosh[\pi(m+n)\sqrt{3}] - \cos[\pi(m-n)]}{2\pi^2(m^2+mn+n^2)}, \quad (65)$$

where

$$\phi(m, n) \equiv \prod_{k=1}^{\infty} \left[ 1 + \left( \frac{m+n}{k+m} \right)^3 \right], \quad (66)$$

$$\prod_{k=1}^{\infty} \left[ 1 + \left( \frac{n}{k} \right)^3 \right] \prod_{k=1}^{\infty} \left[ 1 + 3 \left( \frac{n}{n+2k} \right)^2 \right] = \frac{\Gamma(\frac{1}{2}n)}{\Gamma[\frac{1}{2}(n+1)]} \frac{\cosh(\pi n\sqrt{3}) - \cos(\pi n)}{2^{n+2}\pi^{3/2}n} \quad (67)$$

(Berndt 1994).

The following ASYMPTOTIC SERIES is occasionally useful in probability theory (e.g., the 1-D RANDOM WALK):

$$\frac{\Gamma(J + \frac{1}{2})}{\Gamma(J)} = \sqrt{J} \left( 1 - \frac{1}{8J} + \frac{1}{128J^2} + \frac{5}{1024J^3} - \frac{21}{32768J^4} + \cdots \right) \quad (68)$$

(Graham *et al.* 1994). This series also gives a nice asymptotic generalization of STIRLING NUMBERS OF THE FIRST KIND to fractional values.

It has long been known that  $\Gamma(\frac{1}{4})\pi^{-1/4}$  is TRANSCENDENTAL (Davis 1959), as is  $\Gamma(\frac{1}{3})$  (Le Lionnais 1983), and Chudnovsky has apparently recently proved that  $\Gamma(\frac{1}{4})$  is itself TRANSCENDENTAL.

The upper incomplete gamma function is given by

$$\Gamma(a, x) \equiv \int_x^{\infty} t^{a-1} e^{-t} dt = 1 - \gamma(a, x), \quad (69)$$

where  $\gamma$  is the lower incomplete gamma function. For  $a$  an INTEGER  $n$

$$\Gamma(n, x) = (n-1)! e^{-x} \sum_{s=0}^{n-1} \frac{x^s}{s!} = (n-1)! e^{-x} \text{es}_{n-1}(x), \quad (70)$$

where  $\text{es}$  is the EXPONENTIAL SUM FUNCTION. The lower incomplete gamma function is given by

$$\begin{aligned} \gamma(a, x) &\equiv \Gamma(a) - \Gamma(a, x) = \int_0^x e^{-t} t^{a-1} dt \\ &= a^{-1} x^a e^{-x} {}_1F_1(1; 1+a; x) \\ &= a^{-1} x^a {}_1F_1(a; 1+a; -x), \end{aligned} \quad (71)$$

where  ${}_1F_1(a; b; x)$  is the CONFLUENT HYPERGEOMETRIC FUNCTION OF THE FIRST KIND. For  $a$  an INTEGER  $n$ ,

$$\begin{aligned} \gamma(n, x) &= (n-1)! \left( 1 - e^{-x} \sum_{s=0}^{n-1} \frac{x^s}{s!} \right) \\ &= (n-1)! [1 - \text{es}_{n-1}(x)]. \end{aligned} \quad (72)$$

The function  $\Gamma(a, z)$  is denoted **Gamma[a, z]** and the function  $\gamma(a, z)$  is denoted **Gamma[a, 0, z]** in *Mathematica*® (Wolfram Research, Champaign, IL).

### Gauss-Bolyai-Lobachevsky Space

A non-Euclidean space with constant NEGATIVE GAUSSIAN CURVATURE.

see also LOBACHEVSKY-BOLYAI-GAUSS GEOMETRY, NON-EUCLIDEAN GEOMETRY

### Gauss-Bonnet Formula

The Gauss-Bonnet formula has several formulations. The simplest one expresses the total GAUSSIAN CURVATURE of an embedded triangle in terms of the total GEODESIC CURVATURE of the boundary and the JUMP ANGLES at the corners.

More specifically, if  $M$  is any 2-D RIEMANNIAN MANIFOLD (like a surface in 3-space) and if  $T$  is an embedded triangle, then the Gauss-Bonnet formula states that the integral over the whole triangle of the GAUSSIAN CURVATURE with respect to AREA is given by  $2\pi$  minus the sum of the JUMP ANGLES minus the integral of the GEODESIC CURVATURE over the whole of the boundary of the triangle (with respect to ARC LENGTH),

$$\iint_T K dA = 2\pi - \sum \alpha_i - \int_{\partial T} \kappa_g ds, \quad (1)$$

where  $K$  is the GAUSSIAN CURVATURE,  $dA$  is the AREA measure, the  $\alpha_i$ s are the JUMP ANGLES of  $\partial T$ , and  $\kappa_g$  is the GEODESIC CURVATURE of  $\partial T$ , with  $ds$  the ARC LENGTH measure.

The next most common formulation of the Gauss-Bonnet formula is that for any compact, boundaryless

2-D RIEMANNIAN MANIFOLD, the integral of the GAUSSIAN CURVATURE over the entire MANIFOLD with respect to AREA is  $2\pi$  times the EULER CHARACTERISTIC of the MANIFOLD,

$$\iint_M K dA = 2\pi\chi(M). \quad (2)$$

This is somewhat surprising because the total GAUSSIAN CURVATURE is differential-geometric in character, but the EULER CHARACTERISTIC is topological in character and does not depend on differential geometry at all. So if you distort the surface and change the curvature at any location, regardless of how you do it, the same total curvature is maintained.

Another way of looking at the Gauss-Bonnet theorem for surfaces in 3-space is that the GAUSS MAP of the surface has DEGREE given by half the EULER CHARACTERISTIC of the surface

$$\iint_M K dA = 2\pi\chi(M) - \sum \alpha_i - \int_{\partial M} \kappa_g ds, \quad (3)$$

which works only for ORIENTABLE SURFACES. This makes the Gauss-Bonnet theorem a simple consequence of the POINCARÉ-HOPF INDEX THEOREM, which is a nice way of looking at things if you're a topologist, but not so nice for a differential geometer. This proof can be found in Guillemin and Pollack (1974). Millman and Parker (1977) give a standard differential-geometric proof of the Gauss-Bonnet theorem, and Singer and Thorpe (1996) give a GAUSS'S THEOREMA EGREGIUM-inspired proof which is entirely intrinsic, without any reference to the ambient EUCLIDEAN SPACE.

A general Gauss-Bonnet formula that takes into account both formulas can also be given. For any compact 2-D RIEMANNIAN MANIFOLD with corners, the integral of the GAUSSIAN CURVATURE over the 2-MANIFOLD with respect to AREA is  $2\pi$  times the EULER CHARACTERISTIC of the MANIFOLD minus the sum of the JUMP ANGLES and the total GEODESIC CURVATURE of the boundary.

### Gauss-Bonnet Theorem

see GAUSS-BONNET FORMULA

## Gauss's Circle Problem

Count the number of LATTICE POINTS  $N(r)$  inside the boundary of a CIRCLE of RADIUS  $r$  with center at the origin. The exact solution is given by the SUM

$$N(r) = 1 + 4[r] + 4 \sum_{i=1}^{\lfloor r \rfloor} \left\lfloor \sqrt{r^2 - i^2} \right\rfloor. \quad (1)$$

The first few values are 1, 5, 13, 29, 49, 81, 113, 149, ... (Sloane's A000328).

Gauss showed that

$$N(r) = \pi r^2 + E(r), \quad (2)$$

where

$$|E(r)| \leq 2\sqrt{2}\pi r. \quad (3)$$

Writing  $|E(r)| \leq Cr^\theta$ , the best bounds on  $\theta$  are  $1/2 < \theta \leq 46/73 \approx 0.630137$  (Huxley 1990). The problem has also been extended to CONICS and higher dimensions. The limit  $1/2$  was obtained by Hardy and Landau (1915), and the limit  $46/73$  improves previous values of  $24/37 \approx 0.64864$  (Cheng 1963) and  $34/53 \approx 0.64150$  (Vinogradov), and  $7/11 \approx 0.63636$ .

## Gauss's Class Number Conjecture

In his monumental treatise *Disquisitiones Arithmeticae*, Gauss conjectured that the CLASS NUMBER  $h(-d)$  of an IMAGINARY quadratic field with DISCRIMINANT  $-d$  tends to infinity with  $d$ . A proof was finally given by Heilbronn (1934), and Siegel (1936) showed that for any  $\epsilon > 0$ , there exists a constant  $c_\epsilon > 0$  such that

$$h(-d) > c_\epsilon d^{1/2-\epsilon}$$

as  $d \rightarrow \infty$ . However, these results were not effective in actually determining the values for a given  $m$  of a complete list of fundamental discriminants  $-d$  such that  $h(-d) = m$ , a problem known as GAUSS'S CLASS NUMBER PROBLEM.

Goldfeld (1976) showed that if there exists a "Weil curve" whose associated DIRICHLET  $L$ -SERIES has a zero of at least third order at  $s = 1$ , then for any  $\epsilon > 0$ , there exists an effectively computable constant  $c_\epsilon$  such that

$$h(-d) > c_\epsilon (\ln d)^{1-\epsilon}.$$

Gross and Zaiger (1983) showed that certain curves must satisfy the condition of Goldfeld, and Goldfeld's proof was simplified by Oesterlé (1985).

## Gauss's Class Number Problem

For a given  $m$ , determine a complete list of fundamental DISCRIMINANTS  $-d$  such that the CLASS NUMBER is given by  $h(-d) = m$ . Heegner (1952) gave a solution for  $m = 1$ , but it was not completely accepted due to a number of apparent gaps. However, subsequent examination of Heegner's proof show it to be "essentially" correct (Conway and Guy 1996). Conway and Guy (1996) therefore call the nine values of  $n(-d)$  having  $h(-d) = 1$  where  $-d$  is the DISCRIMINANT corresponding to a QUADRATIC FIELD  $a + b\sqrt{-n}$  ( $n = -1, -2, -3, -7, -11, -19, -43, -67$ , and  $-163$ ; Sloane's A003173) the HEEGNER NUMBERS. The HEEGNER NUMBERS have a number of fascinating properties.

Stark (1967) and Baker (1966) gave independent proofs of the fact that only nine such numbers exist; both proofs were accepted. Baker (1971) and Stark (1975) subsequently and independently solved the generalized class number problem completely for  $m = 2$ . Oesterlé (1985) solved the case  $m = 3$ , and Arno (1992) solved the case  $m = 4$ . Wagner (1996) solve the cases  $n = 5, 6$ , and  $7$ . Arno *et al.* (1993) solved the problem for ODD  $m$  satisfying  $5 \leq m \leq 23$ .

**Gauss-Jordan Elimination**

A method for finding a MATRIX INVERSE. To apply Gauss-Jordan elimination, operate on a MATRIX

$$[A \ I] \equiv \begin{bmatrix} a_{11} & \cdots & a_{1n} & 1 & 0 & \cdots & 0 \\ a_{21} & \cdots & a_{2n} & 0 & 1 & \cdots & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} & 0 & 0 & \cdots & 1 \end{bmatrix},$$

where  $I$  is the IDENTITY MATRIX, to obtain a MATRIX of the form

$$\begin{bmatrix} 1 & 0 & \cdots & 0 & b_{11} & \cdots & b_{1n} \\ 0 & 1 & \cdots & 0 & b_{21} & \cdots & b_{2n} \\ \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 & b_{n1} & \cdots & b_{nn} \end{bmatrix}.$$

The MATRIX

$$B \equiv \begin{bmatrix} b_{11} & \cdots & b_{1n} \\ b_{21} & \cdots & b_{2n} \\ \vdots & \ddots & \vdots \\ b_{n1} & \cdots & b_{nn} \end{bmatrix}$$

is then the MATRIX INVERSE of  $A$ . The procedure is numerically unstable unless PIVOTING (exchanging rows and columns as appropriate) is used. Picking the largest available element as the pivot is usually a good choice.

**Gauss-Kummer Series**

$$\begin{aligned} {}_2F_1\left(-\frac{1}{2}, -\frac{1}{2}; 1; h^2\right) &= \sum_{n=0}^{\infty} \left(\frac{1}{2}\right)_n^2 h^{2n} \\ &= 1 + \frac{1}{4}h^2 + \frac{1}{64}h^4 + \frac{1}{256}h^6 + \dots, \end{aligned}$$

where  ${}_2F_1(a, b; c; x)$  is a HYPERGEOMETRIC FUNCTION. This can be derived using KUMMER'S QUADRATIC TRANSFORMATION.

**Gauss-Kuzmin-Wirsing Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let  $x_0$  be a random number from  $[0, 1]$  written as a simple CONTINUED FRACTION

$$x_0 = 0 + \frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots}}}. \quad (1)$$

Define

$$\begin{aligned} x_n &= 0 + \frac{1}{a_{n+1} + \frac{1}{a_{n+2} + \frac{1}{a_{n+3} + \dots}}} \\ &= \frac{1}{x_{n-1}} - \left\lfloor \frac{1}{x_{n-1}} \right\rfloor. \end{aligned} \quad (2)$$

Gauss (1800) showed that if  $F(n, x)$  is the probability that  $x_n < x$ , then

$$\lim_{n \rightarrow \infty} F(n, x) = \frac{\ln(1+x)}{\ln 2}. \quad (3)$$

Kuzmin (1928) published the first proof, which was subsequently improved by Lévy (1929). Wirsing (1974) showed, among other results, that

$$\lim_{n \rightarrow \infty} \frac{F(n, x) - \frac{\ln(1+x)}{\ln 2}}{(-\lambda)^n} = \Psi(x), \quad (4)$$

where  $\lambda = 0.3036630029\dots$  and  $\Psi(x)$  is an analytic function with  $\Psi(0) = \Psi(1) = 0$ . This constant is connected to the efficiency of the EUCLIDEAN ALGORITHM (Knuth 1981).

The Gauss map is a function from an ORIENTABLE SURFACE in EUCLIDEAN SPACE to a SPHERE. It associates to every point on the surface its oriented NORMAL VECTOR. For surfaces in 3-space, the Gauss map of the surface has DEGREE given by half the EULER CHARACTERISTIC of the surface

$$\iint_M K dA = 2\pi\chi(M) - \sum \alpha_i - \int_{\partial M} \kappa_g ds,$$

which works only for ORIENTABLE SURFACES.

**Gauss's Polynomial Theorem**

If a POLYNOMIAL

$$f(x) = x^N + C_1 x^{N-1} + C_2 x^{N-2} + \cdots + C_N$$

with integral COEFFICIENTS is divisible into a product of two POLYNOMIALS  $f = \psi\phi$ 

$$\begin{aligned} \psi &= x^m + \alpha_1 x^{m-1} + \cdots + \alpha_m \\ \phi &= x^n + \beta_1 x^{n-1} + \cdots + \beta_n, \end{aligned}$$

then the COEFFICIENTS of this POLYNOMIAL are INTEGERS.

### Gauss's Theorema Egregium

Gauss's theorema egregium states that the GAUSSIAN CURVATURE of a surface embedded in 3-space may be understood intrinsically to that surface. "Residents" of the surface may observe the GAUSSIAN CURVATURE of the surface without ever venturing into full 3-dimensional space; they can observe the curvature of the surface they live in without even knowing about the 3-dimensional space in which they are embedded.

In particular, GAUSSIAN CURVATURE can be measured by checking how closely the ARC LENGTH of small RADIUS CIRCLES correspond to what they should be in EUCLIDEAN SPACE,  $2\pi r$ . If the ARC LENGTH of CIRCLES tends to be smaller than what is expected in EUCLIDEAN SPACE, then the space is positively curved; if larger, negatively; if the same, 0 GAUSSIAN CURVATURE.

Gauss (effectively) expressed the theorema egregium by saying that the GAUSSIAN CURVATURE at a point is given by  $-R(v, w)v, w$ , where  $R$  is the RIEMANN TENSOR, and  $v$  and  $w$  are an orthonormal basis for the TANGENT SPACE.

### Gauss's Transformation

If

$$(1 + x \sin^2 \alpha) \sin \beta = (1 + x) \sin \alpha,$$

then

$$(1 + x) \int_0^\alpha \frac{d\phi}{\sqrt{1 - x^2 \sin^2 \phi}} = \int_0^\beta \frac{d\phi}{\sqrt{1 - \frac{4x}{(1+x)^2} \sin^2 \phi}}.$$

### Gaussian Approximation Algorithm

see ARITHMETIC-GEOMETRIC MEAN

### Gaussian Bivariate Distribution

The Gaussian bivariate distribution is given by

$$P(x_1, x_2) = \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \exp\left[-\frac{z}{2(1-\rho^2)}\right], \quad (1)$$

where

$$z \equiv \frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2}, \quad (2)$$

and

$$\rho \equiv \text{cov}(x_1, x_2) = \frac{\langle x_1 x_2 \rangle - \langle x_1 \rangle \langle x_2 \rangle}{\sigma_1 \sigma_2} \quad (3)$$

is the COVARIANCE. Let  $X_1$  and  $X_2$  be normally and independently distributed variates with MEAN 0 and VARIANCE 1. Then define

$$Y_1 \equiv \mu_1 + \sigma_{11}X_1 + \sigma_{12}X_2 \quad (4)$$

$$Y_2 \equiv \mu_2 + \sigma_{21}X_1 + \sigma_{22}X_2. \quad (5)$$

These new variates are normally distributed with MEAN  $\mu_1$  and  $\mu_2$ , VARIANCE

$$\sigma_1^2 \equiv \sigma_{11}^2 + \sigma_{12}^2 \quad (6)$$

$$\sigma_2^2 \equiv \sigma_{21}^2 + \sigma_{22}^2, \quad (7)$$

and COVARIANCE

$$V_{12} \equiv \sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}. \quad (8)$$

The COVARIANCE matrix is

$$V_{ij} = \begin{bmatrix} \sigma_1^2 & \rho\sigma_1\sigma_2 \\ \rho\sigma_1\sigma_2 & \sigma_2^2 \end{bmatrix}, \quad (9)$$

where

$$\rho \equiv \frac{V_{12}}{\sigma_1\sigma_2} = \frac{\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}}{\sigma_1\sigma_2}. \quad (10)$$

The joint probability density function for  $x_1$  and  $x_2$  is

$$f(x_1, x_2) dx_1 dx_2 = \frac{1}{2\pi} e^{-(x_1^2 + x_2^2)/2} dx_1 dx_2. \quad (11)$$

However, from (4) and (5) we have

$$\begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix} = \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}. \quad (12)$$

Now, if

$$\begin{vmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{vmatrix} \neq 0, \quad (13)$$

then this can be inverted to give

$$\begin{aligned} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} &= \begin{bmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{bmatrix}^{-1} \begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix} \\ &= \frac{1}{\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}} \begin{bmatrix} \sigma_{22} & -\sigma_{12} \\ -\sigma_{21} & \sigma_{11} \end{bmatrix} \begin{bmatrix} y_1 - \mu_1 \\ y_2 - \mu_2 \end{bmatrix}. \end{aligned} \quad (14)$$

Therefore,

$$\begin{aligned} x_1^2 + x_2^2 &= \frac{[\sigma_{22}(y_1 - \mu_1) - \sigma_{12}(y_2 - \mu_2)]^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2} \\ &\quad + \frac{[-\sigma_{21}(y_1 - \mu_1) + \sigma_{11}(y_2 - \mu_2)]^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2}. \end{aligned} \quad (15)$$

Expanding the NUMERATOR gives

$$\begin{aligned} & \sigma_{22}^2(y_1 - \mu_1)^2 - 2\sigma_{12}\sigma_{22}(y_1 - \mu_1)(y_2 - \mu_2) \\ & + \sigma_{12}^2(y_2 - \mu_2)^2 + \sigma_{21}^2(y_1 - \mu_1)^2 \\ & - 2\sigma_{11}\sigma_{21}(y_1 - \mu_1)(y_2 - \mu_2) + \sigma_{11}^2(y_2 - \mu_2)^2, \end{aligned} \quad (16)$$

so

$$\begin{aligned} & (x_1^2 + x_2^2)(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2 \\ & = (y_1 - \mu_1)^2(\sigma_{21}^2 + \sigma_{22}^2) \\ & \quad - 2(y_1 - \mu_1)(y_2 - \mu_2)(\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22}) \\ & \quad + (y_2 - \mu_2)^2(\sigma_{11}^2 + \sigma_{12}^2) \\ & = \sigma_2^2(y_1 - \mu_1)^2 - 2(y_1 - \mu_1)(y_2 - \mu_2)(\rho\sigma_1\sigma_2) \\ & \quad + \sigma_1^2(y_2 - \mu_2)^2 \\ & = \sigma_1^2\sigma_2^2 \left[ \frac{(y_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1 - \mu_1)(y_2 - \mu_2)}{\sigma_1\sigma_2} \right. \\ & \quad \left. + \frac{(y_2 - \mu_2)^2}{\sigma_2^2} \right]. \end{aligned} \quad (17)$$

But

$$\begin{aligned} \frac{1}{1 - \rho^2} &= \frac{1}{1 - \frac{V_{12}^2}{\sigma_1^2\sigma_2^2}} = \frac{\sigma_1^2\sigma_2^2}{\sigma_1^2\sigma_2^2 - V_{12}^2} \\ &= \frac{\sigma_1^2\sigma_2^2}{(\sigma_{11}^2 + \sigma_{12}^2)(\sigma_{21}^2 + \sigma_{22}^2) - (\sigma_{11}\sigma_{21} + \sigma_{12}\sigma_{22})^2}. \end{aligned} \quad (18)$$

The DENOMINATOR is

$$\begin{aligned} & \sigma_{11}^2\sigma_{21}^2 + \sigma_{11}^2\sigma_{22}^2 + \sigma_{12}^2\sigma_{21}^2 + \sigma_{12}^2\sigma_{22}^2 - \sigma_{11}^2\sigma_{21}^2 \\ & - 2\sigma_{11}\sigma_{12}\sigma_{21}\sigma_{22} - \sigma_{12}^2\sigma_{22}^2 = (\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2, \end{aligned} \quad (19)$$

so

$$\frac{1}{1 - \rho^2} = \frac{\sigma_1^2\sigma_2^2}{(\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21})^2} \quad (20)$$

and

$$\begin{aligned} & x_1^2 + x_2^2 = \frac{1}{1 - \rho^2} \\ & \times \left[ \frac{(y_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1 - \mu_1)(y_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(y_2 - \mu_2)^2}{\sigma_2^2} \right]. \end{aligned} \quad (21)$$

Solving for  $x_1$  and  $x_2$  and defining

$$\rho' \equiv \frac{\sigma_1\sigma_2\sqrt{1 - \rho^2}}{\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}} \quad (22)$$

gives

$$x_1 = \frac{\sigma_{22}(y_1 - \mu_1) - \sigma_{12}(y_2 - \mu_2)}{\rho'} \quad (23)$$

$$x_2 = \frac{-\sigma_{21}(y_1 - \mu_1) + \sigma_{11}(y_2 - \mu_2)}{\rho'}. \quad (24)$$

The JACOBIAN is

$$\begin{aligned} J \left( \frac{x_1, x_2}{y_1, y_2} \right) &= \begin{vmatrix} \frac{\partial x_1}{\partial y_1} & \frac{\partial x_1}{\partial y_2} \\ \frac{\partial x_2}{\partial y_1} & \frac{\partial x_2}{\partial y_2} \end{vmatrix} = \begin{vmatrix} \frac{\sigma_{22}}{\rho'} & -\frac{\sigma_{12}}{\rho'} \\ -\frac{\sigma_{21}}{\rho'} & \frac{\sigma_{11}}{\rho'} \end{vmatrix} \\ &= \frac{1}{\rho'^2} (\sigma_{11}\sigma_{22} - \sigma_{12}\sigma_{21}) \\ &= \frac{1}{\rho'} = \frac{1}{\sigma_1\sigma_2\sqrt{1 - \rho^2}}. \end{aligned} \quad (25)$$

Therefore,

$$dx_1 dx_2 = \frac{dy_1 dy_2}{\sigma_1\sigma_2\sqrt{1 - \rho^2}} \quad (26)$$

and

$$\begin{aligned} & \frac{1}{2\pi} e^{-(x_1^2 + x_2^2)/2} dx_1 dx_2 \\ &= \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1 - \rho^2}} e^{-v/2} dy_1 dy_2, \end{aligned} \quad (27)$$

where

$$\begin{aligned} v &\equiv \frac{1}{1 - \rho^2} \\ &\times \left[ \frac{(y_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(y_1 - \mu_1)(y_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(y_2 - \mu_2)^2}{\sigma_2^2} \right]. \end{aligned} \quad (28)$$

Now, if

$$\begin{vmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{vmatrix} = 0, \quad (29)$$

then

$$\sigma_{11}\sigma_{12} = \sigma_{12}\sigma_{21} \quad (30)$$

$$y_1 = \mu_1 + \sigma_{11}x_1 + \sigma_{12}x_2 \quad (31)$$

$$\begin{aligned} y_2 &= \mu_2 + \frac{\sigma_{12}\sigma_{21}}{\sigma_{11}}x_2 = \mu_2 + \frac{\sigma_{11}\sigma_{21}x_1 + \sigma_{12}\sigma_{21}x_2}{\sigma_{11}} \\ &= \mu_2 + \frac{\sigma_{21}}{\sigma_{11}}(\sigma_{11}x_1 + \sigma_{12}x_2), \end{aligned} \quad (32)$$

so

$$y_1 = \mu_1 + x_3 \quad (33)$$

$$y_2 = \mu_2 + \frac{\sigma_{21}}{\sigma_{11}}x_3, \quad (34)$$

where

$$x_3 = y_1 - \mu_1 = \frac{\sigma_{11}}{\sigma_{21}}(y_2 - \mu_2). \quad (35)$$

The CHARACTERISTIC FUNCTION is given by

$$\begin{aligned} \phi(t_1, t_2) &\equiv \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{i(t_1x_1 + t_2x_2)} P(x_1, x_2) dx_1 dx_2 \\ &= N \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{i(t_1x_1 + t_2x_2)} \exp \left[ -\frac{z}{2(1 - \rho^2)} \right] dx_1 dx_2, \end{aligned} \quad (36)$$

where

$$z \equiv \left[ \frac{(x_1 - \mu_1)^2}{\sigma_1^2} - \frac{2\rho(x_1 - \mu_1)(x_2 - \mu_2)}{\sigma_1\sigma_2} + \frac{(x_2 - \mu_2)^2}{\sigma_2^2} \right] \quad (37)$$

and

$$N \equiv \frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}. \quad (38)$$

Now let

$$u \equiv x_1 - \mu_1 \quad (39)$$

$$w \equiv x_2 - \mu_2. \quad (40)$$

Then

$$\begin{aligned} \phi(t_1, t_2) &= N' \int_{-\infty}^{\infty} \left( e^{it_2 w} \exp \left[ -\frac{1}{2(1-\rho^2)} \frac{w^2}{\sigma_2^2} \right] \right) \\ &\quad \times \int_{-\infty}^{\infty} e^v e^{t_1 u} du dw, \quad (41) \end{aligned}$$

where

$$\begin{aligned} v &= -\frac{1}{2(1-\rho^2)} \frac{1}{\sigma_1^2} \left[ u^2 - \frac{2\rho\sigma_1 w}{\sigma_2} u \right] \\ N' &\equiv \frac{e^{i(t_1\mu_1+t_2\mu_2)}}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}}. \quad (42) \end{aligned}$$

COMPLETE THE SQUARE in the inner integral

$$\begin{aligned} \int_{-\infty}^{\infty} \exp \left\{ -\frac{1}{2(1-\rho^2)} \frac{1}{\sigma_1^2} \left[ u^2 - \frac{2\rho\sigma_1 w}{\sigma_2} u \right] \right\} e^{t_1 u} du \\ = \int_{-\infty}^{\infty} \exp \left\{ -\frac{1}{2\sigma_1^2(1-\rho^2)} \left[ u - \frac{\rho_1\sigma_1 w}{\sigma_2} \right]^2 \right\} \\ \times \left\{ \frac{1}{2\sigma_1^2(1-\rho^2)} \left( \frac{\rho_1\sigma_1 w}{\sigma_2} \right)^2 \right\} e^{it_1 u} du. \quad (43) \end{aligned}$$

Rearranging to bring the exponential depending on  $w$  outside the inner integral, letting

$$v \equiv u - \rho \frac{\sigma_1 w}{\sigma_2}, \quad (44)$$

and writing

$$e^{it_1 u} = \cos(t_1 u) + i \sin(t_1 u) \quad (45)$$

gives

$$\begin{aligned} \phi(t_1, t_2) &= N' \int_{-\infty}^{\infty} e^{it_2 w} \exp \left[ -\frac{1}{2\sigma_2^2(1-\rho^2)} w^2 \right] \\ &\quad \times \exp \left[ \frac{\rho^2}{2\sigma_2^2(1-\rho^2)} w^2 \right] \int_{-\infty}^{\infty} \exp \left[ -\frac{1}{2\sigma_2^2(1-\rho^2)} v^2 \right] \\ &\quad \times \left\{ \cos \left[ t_1 \left( v + \frac{\rho\sigma_1 w}{\sigma_2} \right) \right] \right. \\ &\quad \left. + i \sin \left[ t_1 \left( v + \frac{\rho\sigma_1 w}{\sigma_2} \right) \right] \right\} dv dw. \quad (46) \end{aligned}$$

Expanding the term in braces gives

$$\begin{aligned} &\left[ \cos(t_1 v) \cos \left( \frac{\rho\sigma_1 w t_1}{\sigma_2} \right) - \sin(t_1 v) \sin \left( \frac{\rho\sigma_1 w}{\sigma_2 t_1} \right) \right] \\ &\quad + i \left[ \sin(t_1 v) \cos \left( \frac{\rho\sigma_1 w}{\sigma_2 t_1} \right) + \cos(t_1 v) \sin \left( \frac{\rho\sigma_1 w t_1}{\sigma_2} \right) \right] \\ &= \left[ \cos \left( \frac{\rho\sigma_1 w t_1}{\sigma_2} \right) + i \sin \left( \frac{\rho\sigma_1 w t_1}{\sigma_2} \right) \right] \\ &= \exp \left( \frac{i\rho\sigma_1 w}{\sigma_2} t_1 \right) [\cos(t_1 v) + i \sin(t_1 v)]. \quad (47) \end{aligned}$$

But  $e^{-ax^2} \sin(bx)$  is ODD, so the integral over the sine term vanishes, and we are left with

$$\begin{aligned} \phi(t_1, t_2) &= N' \int_{-\infty}^{\infty} e^{it_2 w} \exp \left[ -\frac{w^2}{2\sigma_2^2} \right] \\ &\quad \times \exp \left[ \frac{\rho^2 w^2}{2\sigma_2^2(1-\rho^2)} \right] \exp \left[ \frac{i\rho\sigma_1 w t_1}{\sigma_2} \right] dw \\ &\quad \times \int_{-\infty}^{\infty} \exp \left[ -\frac{v^2}{2\sigma_1^2(1-\rho^2)} \right] \cos(t_1 v) dv \\ &= N' \int_{-\infty}^{\infty} \exp \left[ iw \left( t_2 + t_1 \left( \rho \frac{\sigma_1}{\sigma_2} \right) \right) \right] \exp \left[ -\frac{w^2}{2\sigma_2^2} \right] dw \\ &\quad \times \int_{-\infty}^{\infty} \exp \left[ -\frac{v^2}{2\sigma_1^2(1-\rho^2)} \right] \cos(t_1 v) dv. \quad (48) \end{aligned}$$

Now evaluate the GAUSSIAN INTEGRAL

$$\begin{aligned} \int_{-\infty}^{\infty} e^{ikx} e^{-ax^2} dx &= \int_{-\infty}^{\infty} e^{-ax^2} \cos(kx) dx \\ &= \sqrt{\frac{\pi}{a}} e^{-k^2/4a} \quad (49) \end{aligned}$$

to obtain the explicit form of the CHARACTERISTIC FUNCTION,

$$\begin{aligned} \phi(t_1, t_2) &= \frac{e^{i(t_1\mu_1+t_2\mu_2)}}{2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}} \\ &\quad \times \left\{ \sigma_2 \sqrt{2\pi} \exp \left[ -\frac{1}{4} \left( t_2 + \rho \frac{\sigma_1}{\sigma_2} t_1 \right)^2 2\sigma_2^2 \right] \right\} \\ &\quad \times \left\{ \sigma_1 \sqrt{2\pi(1-\rho^2)} \exp \left[ -\frac{1}{4} t_1^2 2\sigma_1^2(1-\rho^2) \right] \right\} \\ &= e^{i(t_1\mu_1+t_2\mu_2)} \exp \left\{ -\frac{1}{2} [t_2^2 \sigma_2^2 + 2\rho\sigma_1\sigma_2 t_1 t_2 \right. \\ &\quad \left. + \rho^2 \sigma_1^2 t_1^2 + (1-\rho^2) \sigma_1^2 t_1^2] \right\} \\ &= \exp [i(t_1\mu_1 + t_2\mu_2) \\ &\quad - \frac{1}{2} (\sigma_1^2 t_1^2 + 2\rho\sigma_1\sigma_2 t_1 t_2 + \sigma_2^2 t_2^2)]. \quad (50) \end{aligned}$$

Let  $z_1$  and  $z_2$  be two independent Gaussian variables with MEANS  $\mu_i = 0$  and  $\sigma_i^2 = 1$  for  $i = 1, 2$ . Then the variables  $a_1$  and  $a_2$  defined below are Gaussian bivariate with unit VARIANCE and CROSS-CORRELATION COEFFICIENT  $\rho$ :

$$a_1 = \sqrt{\frac{1+\rho}{2}} z_1 + \sqrt{\frac{1-\rho}{2}} z_2 \quad (51)$$

$$a_2 = \sqrt{\frac{1+\rho}{2}} z_1 - \sqrt{\frac{1-\rho}{2}} z_2. \quad (52)$$

The conditional distribution is

$$P(x_2|x_1) = \frac{1}{\sigma_2 \sqrt{2\pi(1-\rho^2)}} \exp \left[ -\frac{(x_2 - \mu'_2)^2}{2\sigma_2'^2} \right], \quad (53)$$

where

$$\mu'_2 \equiv \mu_2 + \rho \frac{\sigma_2}{\sigma_1} (x_1 - \mu_1) \quad (54)$$

$$\sigma'_2 \equiv \sigma_2 \sqrt{1-\rho^2}. \quad (55)$$

The marginal probability density is

$$\begin{aligned} P(x_2) &= \int_{-\infty}^{\infty} P(x_1, x_2) dx_1 \\ &= \frac{1}{\sigma_2 \sqrt{2\pi}} \exp \left[ -\frac{(x_2 - \mu_2)^2}{2\sigma_2^2} \right]. \end{aligned} \quad (56)$$

#### Gaussian Brackets

Published by Gauss in *Disquisitiones Arithmeticae*. They are defined as follows.

$$[ ] = 1 \quad (1)$$

$$[a_1] = a_1 \quad (2)$$

$$[a_1, a_2] = [a_1]a_2 + [ ] \quad (3)$$

$$\begin{aligned} [a_1, a_2, \dots, a_n] &= [a_1, a_2, \dots, a_{n-1}]a_n \\ &\quad + [a_1, a_2, \dots, a_{n-2}]. \end{aligned} \quad (4)$$

Gaussian brackets are useful for treating CONTINUED FRACTIONS because

$$\frac{1}{a_1 + \frac{1}{a_2 + \frac{1}{a_3 + \dots + \frac{1}{a_n}}}} = \frac{[a_2, a_n]}{[a_1, a_n]}. \quad (5)$$

The NOTATION  $[x]$  conflicts with that of GAUSSIAN POLYNOMIALS and the NINT function.

#### Gaussian Coefficient

see *q*-BINOMIAL COEFFICIENT

#### Gaussian Coordinate System

A coordinate system which has a METRIC satisfying  $g_{ii} = -1$  and  $\partial g_{ij}/\partial x_j = 0$ .

#### Gaussian Curvature

An intrinsic property of a space independent of the coordinate system used to describe it. The Gaussian curvature of a REGULAR SURFACE in  $\mathbb{R}^3$  at a point  $\mathbf{p}$  is formally defined as

$$K(\mathbf{p}) = \frac{1}{2} \det(S(\mathbf{p})), \quad (1)$$

where  $S$  is the SHAPE OPERATOR and  $\det$  denotes the DETERMINANT.

If  $\mathbf{x}: U \rightarrow \mathbb{R}^3$  is a REGULAR PATCH, then the Gaussian curvature is given by

$$K = \frac{eg - f^2}{EG - F^2}, \quad (2)$$

where  $E$ ,  $F$ , and  $G$  are coefficients of the first FUNDAMENTAL FORM and  $e$ ,  $f$ , and  $g$  are coefficients of the second FUNDAMENTAL FORM (Gray 1993, p. 282). The Gaussian curvature can be given entirely in terms of the first FUNDAMENTAL FORM

$$ds^2 = E du^2 + 2F du dv + G dv^2 \quad (3)$$

and the DISCRIMINANT

$$g \equiv EG - F^2 \quad (4)$$

by

$$K = \frac{1}{\sqrt{g}} \left[ \frac{\partial}{\partial v} \left( \frac{\sqrt{g}}{E} \Gamma_{11}^2 \right) - \frac{\partial}{\partial u} \left( \frac{\sqrt{g}}{E} \Gamma_{12}^2 \right) \right], \quad (5)$$

where  $\Gamma_{ij}^k$  are the CONNECTION COEFFICIENTS. Equivalently,

$$\begin{aligned} K &= \frac{1}{g^2} \begin{vmatrix} E & F & \frac{\partial F}{\partial v} - \frac{1}{2} \frac{\partial G}{\partial u} \\ F & G & \frac{1}{2} \frac{\partial E}{\partial u} \\ \frac{1}{2} \frac{\partial E}{\partial u} & k_{23} & k_{33} \end{vmatrix} \\ &\quad - \frac{1}{g^2} \begin{vmatrix} E & F & \frac{1}{2} \frac{\partial E}{\partial v} \\ F & G & \frac{1}{2} \frac{\partial G}{\partial v} \\ \frac{1}{2} \frac{\partial E}{\partial v} & \frac{1}{2} \frac{\partial G}{\partial v} & 0 \end{vmatrix}, \end{aligned} \quad (6)$$

where

$$k_{23} \equiv \frac{\partial F}{\partial u} - \frac{1}{2} \frac{\partial E}{\partial v} \quad (7)$$

$$k_{33} \equiv -\frac{1}{2} \frac{\partial^2 E}{\partial v^2} + \frac{\partial^2 F}{\partial u \partial v} - \frac{1}{2} \frac{\partial^2 G}{\partial u^2}. \quad (8)$$

Writing this out,

$$K = \frac{1}{2g} \left[ 2 \frac{\partial^2 F}{\partial u \partial v} - \frac{\partial^2 E}{\partial v^2} - \frac{\partial^2 G}{\partial u^2} \right] - \frac{G}{4g^2} \left[ \frac{\partial E}{\partial u} \left( 2 \frac{\partial F}{\partial v} - \frac{\partial G}{\partial u} \right) - \left( \frac{\partial E}{\partial v} \right)^2 \right] + \frac{F}{4g^2} \left[ \frac{\partial E}{\partial u} \frac{\partial G}{\partial v} - 2 \frac{\partial E}{\partial v} \frac{\partial G}{\partial u} \right] + \left( 2 \frac{\partial F}{\partial u} - \frac{\partial E}{\partial v} \right) \left( 2 \frac{\partial F}{\partial v} - \frac{\partial G}{\partial u} \right) - \frac{E}{4g^2} \left[ \frac{\partial G}{\partial v} \left( 2 \frac{\partial F}{\partial u} - \frac{\partial E}{\partial v} \right) - \left( \frac{\partial G}{\partial u} \right)^2 \right]. \quad (9)$$

The Gaussian curvature is also given by

$$K = \frac{\det(\mathbf{x}_{uu}\mathbf{x}_u\mathbf{x}_v)\det(\mathbf{x}_{vv}\mathbf{x}_u\mathbf{x}_v) - [\det(\mathbf{x}_{uv}\mathbf{x}_u\mathbf{x}_v)]^2}{[|\mathbf{x}_u|^2|\mathbf{x}_v|^2 - (\mathbf{x}_u \cdot \mathbf{x}_v)^2]^2} \quad (10)$$

(Gray 1993, p. 285), as well as

$$K = \frac{[\hat{\mathbf{N}}\hat{\mathbf{N}}_1\hat{\mathbf{N}}_2]}{\sqrt{g}} = \frac{\epsilon^{ij}[\hat{\mathbf{N}}\hat{\mathbf{T}}\hat{\mathbf{T}}_i]_j}{\sqrt{g}}, \quad (11)$$

where  $\epsilon^{ij}$  is the LEVI-CIVITA SYMBOL,  $\hat{\mathbf{N}}$  is the unit NORMAL VECTOR and  $\hat{\mathbf{T}}$  is the unit TANGENT VECTOR. The Gaussian curvature is also given by

$$K = -\frac{R}{2} = \kappa_1\kappa_2 = \frac{1}{R_1R_2}, \quad (12)$$

where  $R$  is the CURVATURE SCALAR,  $\kappa_1$  and  $\kappa_2$  the PRINCIPAL CURVATURES, and  $R_1$  and  $R_2$  the PRINCIPAL RADII OF CURVATURE. For a MONGE PATCH with  $z = h(u, v)$ ,

$$K = \frac{h_{uu}h_{vv} - h_{uv}^2}{(1 + h_u^2 + h_v^2)^2}. \quad (13)$$

The Gaussian curvature  $K$  and MEAN CURVATURE  $H$  satisfy

$$H^2 \geq K, \quad (14)$$

with equality only at UMBILIC POINTS, since

$$H^2 - K^2 = \frac{1}{4}(\kappa_1 - \kappa_2)^2. \quad (15)$$

If  $\mathbf{p}$  is a point on a REGULAR SURFACE  $M \subset \mathbb{R}^3$  and  $\mathbf{v}_\mathbf{p}$  and  $\mathbf{w}_\mathbf{p}$  are tangent vectors to  $M$  at  $\mathbf{p}$ , then the Gaussian curvature of  $M$  at  $\mathbf{p}$  is related to the SHAPE OPERATOR  $S$  by

$$S(\mathbf{v}_\mathbf{p}) \times S(\mathbf{w}_\mathbf{p}) = K(\mathbf{p})\mathbf{v}_\mathbf{p} \times \mathbf{w}_\mathbf{p}. \quad (16)$$

Let  $\mathbf{Z}$  be a nonvanishing VECTOR FIELD on  $M$  which is everywhere PERPENDICULAR to  $M$ , and let  $V$  and  $W$  be

VECTOR FIELDS tangent to  $M$  such that  $V \times W = \mathbf{Z}$ , then

$$K = \frac{\mathbf{Z} \cdot (D_V \mathbf{Z} \times D_W \mathbf{Z})}{2|\mathbf{Z}|^4} \quad (17)$$

(Gray 1993, pp. 291–292).

For a SPHERE, the Gaussian quadrature is  $K = 1/a^2$ . For EUCLIDEAN SPACE, the Gaussian quadrature is  $K = 0$ . For GAUSS-BOLYAI-LOBACHEVSKY SPACE, the Gaussian quadrature is  $K = -1/a^2$ . A FLAT SURFACE is a REGULAR SURFACE and special class of MINIMAL SURFACE on which Gaussian curvature vanishes everywhere.

A point  $\mathbf{p}$  on a REGULAR SURFACE  $M \in \mathbb{R}^3$  is classified based on the sign of  $K(\mathbf{p})$  as given in the following table (Gray 1993, p. 280), where  $S$  is the SHAPE OPERATOR.

Sign	Point
$K(\mathbf{p}) > 0$	elliptic point
$K(\mathbf{p}) < 0$	hyperbolic point
$K(\mathbf{p}) = 0$ but $S(\mathbf{p}) \neq 0$	parabolic point
$K(\mathbf{p}) = 0$ and $S(\mathbf{p}) = 0$	planar point

A surface on which the Gaussian curvature  $K$  is everywhere POSITIVE is called SYNCLASTIC, while a surface on which  $K$  is everywhere NEGATIVE is called ANTICLASTIC. Surfaces with constant Gaussian curvature include the CONE, CYLINDER, KUEN SURFACE, PLANE, PSEUDOSPHERE, and SPHERE. Of these, the CONE and CYLINDER are the only FLAT SURFACES OF REVOLUTION.

## Gaussian Differential Equation

see HYPERGEOMETRIC DIFFERENTIAL EQUATION

## Gaussian Distribution

The Gaussian probability distribution with MEAN  $\mu$  and STANDARD DEVIATION  $\sigma$  is a GAUSSIAN FUNCTION of the form

$$P(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2}, \quad (1)$$

where  $P(x) dx$  gives the probability that a variate with a Gaussian distribution takes on a value in the range  $[x, x + dx]$ . This distribution is also called the NORMAL DISTRIBUTION or, because of its curved flaring shape, the BELL CURVE. The distribution  $P(x)$  is properly normalized for  $x \in (-\infty, \infty)$  since

$$\int_{-\infty}^{\infty} P(x) dx = 1. \quad (2)$$

The cumulative DISTRIBUTION FUNCTION, which gives the probability that a variate will assume a value  $\leq x$ , is then

$$D(x) \equiv \int_{-\infty}^x P(x) dx = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-(x-\mu)^2/2\sigma^2} dx. \quad (3)$$

Gaussian distributions have many convenient properties, so random variates with unknown distributions are often assumed to be Gaussian, especially in physics and astronomy. Although this can be a dangerous assumption, it is often a good approximation due to a surprising result known as the CENTRAL LIMIT THEOREM. This theorem proves that the MEAN of any set of variates with any distribution having a finite MEAN and VARIANCE tends to the Gaussian distribution. Many common attributes such as test scores, height, etc., follow roughly Gaussian distributions, with few members at the high and low ends and many in the middle.

Making the transformation

$$z \equiv \frac{x - \mu}{\sigma} \quad (4)$$

so that  $dz = dx/\sigma$  gives a variate with unit VARIANCE and 0 MEAN

$$P(x) dx = \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz, \quad (5)$$

known as a standard NORMAL DISTRIBUTION. So defined,  $z$  is known as a  $z$ -SCORE).

The NORMAL DISTRIBUTION FUNCTION gives the probability that a standard normal variate assumes a value in the interval  $[0, z]$ ,

$$\Phi(x) \equiv \frac{1}{\sqrt{2\pi}} \int_0^x e^{-z^2/2} dz = \frac{1}{2} \operatorname{erf} \left( \frac{x}{\sqrt{2}} \right). \quad (6)$$

Here, ERF is a function sometimes called the error function. Neither  $\Phi(z)$  nor ERF can be expressed in terms of finite additions, subtractions, multiplications, and root

extractions, and so both must be either computed numerically or otherwise approximated. The value of  $a$  for which  $P(x)$  falls within the interval  $[-a, a]$  with a given probability  $P$  is called the  $P$  CONFIDENCE INTERVAL.

The Gaussian distribution is also a special case of the CHI-SQUARED DISTRIBUTION, since substituting

$$z \equiv \frac{(x - \mu)^2}{\sigma^2} \quad (7)$$

so that

$$dz = \frac{1}{2} \frac{2(x - \mu)}{\sigma} dx = \sqrt{\frac{z}{\sigma}} dx \quad (8)$$

(where an extra factor of  $1/2$  has been added to  $dz$  since  $z$  runs from 0 to  $\infty$  instead of from  $-\infty$  to  $\infty$ ), gives

$$\begin{aligned} P(x) dx &= \frac{1}{\sqrt{2\pi}} e^{-(z/\sigma)/2} \left( \frac{z}{\sigma} \right)^{-1/2} d \left( \frac{z}{\sigma} \right) dz \\ &= \frac{1}{2^{1/2} \Gamma(\frac{1}{2})} e^{-(z/\sigma)/2} \left( \frac{z}{\sigma} \right)^{-1/2} d \left( \frac{z}{\sigma} \right) dz, \end{aligned} \quad (9)$$

which is a CHI-SQUARED DISTRIBUTION in  $z/\sigma$  with  $r = 1$  (i.e., a GAMMA DISTRIBUTION with  $\alpha = 1/2$  and  $\theta = 2$ ).

Cramer showed in 1936 that if  $X$  and  $Y$  are INDEPENDENT variates and  $X + Y$  has a Gaussian distribution, then both  $X$  and  $Y$  must be Gaussian (CRAMER'S THEOREM).

The ratio  $X/Y$  of independent Gaussian-distributed variates with zero MEAN is distributed with a CAUCHY DISTRIBUTION. This can be seen as follows. Let  $X$  and  $Y$  both have MEAN 0 and standard deviations of  $\sigma_x$  and  $\sigma_y$ , respectively, then the joint probability density function is the GAUSSIAN BIVARIATE DISTRIBUTION with  $\rho = 0$ ,

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y} e^{-[x^2/(2\sigma_x^2) + y^2/(2\sigma_y^2)]}. \quad (10)$$

From RATIO DISTRIBUTION, the distribution of  $U = Y/X$  is

$$\begin{aligned} P(u) &= \int_{-\infty}^{\infty} |x| f(x, ux) dx \\ &= \frac{1}{2\pi\sigma_x\sigma_y} \int_{-\infty}^{\infty} |x| e^{-[x^2/(2\sigma_x^2) + u^2 x^2/(2\sigma_y^2)]} \\ &= \frac{1}{\pi\sigma_x\sigma_y} \int_0^{\infty} x \exp \left[ -x^2 \left( \frac{1}{2\sigma_x^2} + \frac{u^2}{2\sigma_y^2} \right) \right] dx. \end{aligned} \quad (11)$$

But

$$\int_0^{\infty} x e^{-ax^2} dx = \left[ -\frac{1}{2a} e^{-ax^2} \right]_0^{\infty} = \frac{1}{2a} [0 - (-1)] = \frac{1}{2a}, \quad (12)$$

so

$$P(u) = \frac{1}{\pi \sigma_x \sigma_y} \frac{1}{2 \left( \frac{1}{2\sigma_x^2} + \frac{u^2}{2\sigma_y^2} \right)} = \frac{1}{\pi} \frac{\sigma_x \sigma_y}{u^2 \sigma_x^2 + \sigma_y^2}$$

$$= \frac{1}{\pi} \frac{\frac{\sigma_y}{\sigma_x}}{u^2 + \left( \frac{\sigma_y}{\sigma_x} \right)^2}, \quad (13)$$

which is a CAUCHY DISTRIBUTION with MEAN  $\mu = 0$  and full width

$$\Gamma = \frac{2\sigma_y}{\sigma_x}. \quad (14)$$

The CHARACTERISTIC FUNCTION for the Gaussian distribution is

$$\phi(t) = e^{imt - \sigma^2 t^2/2}, \quad (15)$$

and the MOMENT-GENERATING FUNCTION is

$$M(t) = \langle e^{tx} \rangle = \int_{-\infty}^{\infty} \frac{e^{tx}}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2} dx$$

$$= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \exp \left\{ -\frac{1}{2\sigma^2} [x^2 - 2(\mu + \sigma^2 t)x + \mu^2] \right\} dx. \quad (16)$$

COMPLETING THE SQUARE in the exponent,

$$\frac{1}{2\sigma^2} [x^2 - 2(\mu + \sigma^2 t)x + \mu^2]$$

$$= \frac{1}{2\sigma^2} \{ [x - (\mu + \sigma^2 t)]^2 + [\mu^2 - (\mu + \sigma^2 t)^2] \}. \quad (17)$$

Let

$$y \equiv x - (\mu + \sigma^2 t) \quad (18)$$

$$dy = dx \quad (19)$$

$$a \equiv \frac{1}{2\sigma^2}. \quad (20)$$

The integral then becomes

$$M(t) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \exp \left[ -ay^2 + \frac{2\mu\sigma^2 t + \sigma^4 t^2}{2\sigma^2} \right] dy$$

$$= \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} \exp[-ay^2 + \mu t + \frac{1}{2}\sigma^2 t^2] dy$$

$$= \frac{1}{\sigma\sqrt{2\pi}} e^{\mu t + \sigma^2 t^2/2} \int_{-\infty}^{\infty} e^{-ay^2} dy$$

$$= \frac{1}{\sigma\sqrt{2\pi}} \sqrt{\frac{\pi}{a}} e^{\mu t + \sigma^2 t^2/2}$$

$$= \frac{\sqrt{2\sigma^2\pi}}{\sigma\sqrt{2\pi}} e^{\mu t + \sigma^2 t^2/2} = e^{\mu t + \sigma^2 t^2/2}, \quad (21)$$

so

$$M'(t) = (\mu + \sigma^2 t) e^{\mu t + \sigma^2 t^2/2} \quad (22)$$

$$M''(t) = \sigma^2 e^{\mu t + \sigma^2 t^2/2} + e^{\mu t + \sigma^2 t^2/2} (\mu + t\sigma^2)^2, \quad (23)$$

and

$$\mu = M'(0) = \mu \quad (24)$$

$$\sigma^2 = M''(0) - [M'(0)]^2$$

$$= (\sigma^2 + \mu^2) - \mu^2 = \sigma^2. \quad (25)$$

These can also be computed using

$$R(t) = \ln[M(t)] = \mu t + \frac{1}{2}\sigma^2 t^2 \quad (26)$$

$$R'(t) = \mu + \sigma^2 t \quad (27)$$

$$R''(t) = \sigma^2, \quad (28)$$

yielding, as before,

$$\mu = R'(0) = \mu \quad (29)$$

$$\sigma^2 = R''(0) = \sigma^2. \quad (30)$$

The moments can also be computed directly by computing the MOMENTS about the origin  $\mu'_n \equiv \langle x^n \rangle$ ,

$$\mu'_n = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} x^n e^{-(x-\mu)^2/2\sigma^2} dx. \quad (31)$$

Now let

$$u \equiv \frac{x - \mu}{\sqrt{2}\sigma} \quad (32)$$

$$du = \frac{dx}{\sqrt{2}\sigma} \quad (33)$$

$$x = \sigma u \sqrt{2} + \mu, \quad (34)$$

giving

$$\mu'_n = \frac{\sqrt{2}\sigma}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} x^n e^{-u^2} du = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x^n e^{-u^2} du, \quad (35)$$

so

$$\mu'_0 = 1 \quad (36)$$

$$\mu'_1 = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x e^{-u^2} du$$

$$= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} (\sqrt{2}\sigma u + \mu) e^{-u^2} du$$

$$= [\sqrt{2}\sigma H_1(1) + \mu H_0(1)] = (0 + \mu) = \mu \quad (37)$$

$$\mu'_2 = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x^2 e^{-u^2} du$$

$$= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} (2\sigma^2 u^2 + 2\sqrt{2}\sigma\mu u + \mu^2) e^{-u^2} du$$

$$= [2\sigma^2 H_2(1) + 2\sqrt{2}\sigma\mu H_1(1) + \mu^2 H_0(1)]$$

$$= (2\sigma^2 \frac{1}{2} + 0 + \mu^2) = \mu^2 + \sigma^2 \quad (38)$$

$$\mu'_3 = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x^3 e^{-u^2} du$$

$$\begin{aligned}
&= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} (2\sqrt{2}\sigma^3 u^3 + 6\mu\sigma^2 u^2 \\
&\quad + 3\sqrt{2}\mu^2\sigma u + \mu^3) e^{-u^2} du \\
&= [2\sqrt{2}\sigma^3 H_3(1) + 6\mu\sigma^2 H_2(1) \\
&\quad + 3\sqrt{2}\mu^2\sigma H_1(1) + \mu^3 H_0(1)] \\
&= (0 + 6\mu^2\sigma^2 \frac{1}{2} + 0 + \mu^3) = \mu(\mu^2 + 3\sigma^2) \quad (39) \\
\mu'_4 &= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} x^3 e^{-u^2} du \\
&= \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} (4\sigma^4 u^4 + 8\sqrt{2}\mu\sigma^3 u^3 \\
&\quad + 12\mu^2\sigma^2 u^2 + 4\sqrt{2}\mu^3\sigma u + \mu^4) e^{-u^2} du \\
&= [4\sigma^4 H_4(1) + 8\sqrt{2}\mu\sigma^3 H_3(1) + 12\mu^2\sigma^2 H_2(1) \\
&\quad + 4\sqrt{2}\mu^3\sigma H_1(1) + \mu^4 H_0(1)] \\
&= (4\sigma^4 \frac{3}{4} + 0 + 12\mu^2\sigma^2 \frac{1}{2} + 0 + \mu^4) \\
&= \mu^4 + 6\mu^2\sigma^2 + 3\sigma^4, \quad (40)
\end{aligned}$$

where  $H_n(a)$  are GAUSSIAN INTEGRALS.

Now find the MOMENTS about the MEAN,

$$\mu_1 \equiv 0 \quad (41)$$

$$\mu_2 \equiv \mu'_2 - (\mu'_1)^2 = (\mu^2 + \sigma^2) - \mu^2 = \sigma^2 \quad (42)$$

$$\begin{aligned}
\mu_3 &\equiv \mu'_3 - 3\mu'_2\mu'_1 + 2(\mu'_1)^3 \\
&= \mu(\mu^2 + 3\sigma^2) - 3(\sigma^2 + \mu^2)\mu + 2\mu^3 = 0 \quad (43)
\end{aligned}$$

$$\begin{aligned}
\mu_4 &\equiv \mu'_4 - 4\mu'_3\mu'_1 + 6\mu'_2(\mu'_1)^2 - 3(\mu'_1)^4 \\
&= (\mu^4 + 6\mu^2\sigma^2 + 3\sigma^4) - 4(\mu^3 + 3\mu\sigma^2)\mu \\
&\quad + 6(\mu^2 + \sigma^2)\mu^2 - 3\mu^4 \\
&= 3\sigma^4, \quad (44)
\end{aligned}$$

so the VARIANCE, STANDARD DEVIATION, SKEWNESS, and KURTOSIS are given by

$$\text{var}(x) \equiv \mu_2 = \sigma^2 \quad (45)$$

$$\text{stdv}(x) \equiv \sqrt{\text{var}(x)} = \sigma \quad (46)$$

$$\gamma_1 = \frac{\mu_3}{\sigma^3} = 0 \quad (47)$$

$$\gamma_2 = \frac{\mu_4}{\sigma^4} - 3 = \frac{3\sigma^4}{\sigma^4} - 3 = 0. \quad (48)$$

The VARIANCE of the SAMPLE VARIANCE  $s^2$  for a sample taken from a population with a Gaussian distribution is

$$\begin{aligned}
\text{var}(s^2) &= \frac{(N-1)[(N-1)\mu'_4 - (N-3)\mu'^2_2]}{N^3} \\
&= \frac{(N-1)}{N^3} [(N-1)(\mu^4 + 6\mu^2\sigma^2 + 3\sigma^4) \\
&\quad - (N-3)(\mu^2 + \sigma^2)^2] \\
&= \frac{2(N-1)(\mu^4 + 2\mu^2 N\sigma^2 + N\sigma^4)}{N^3}. \quad (49)
\end{aligned}$$

If  $\mu = 0$ , this expression simplifies to

$$\text{var}(s^2) = \frac{2(N-1)N\sigma^4}{N^3} = \frac{2\sigma^4(N-1)}{N^2}, \quad (50)$$

and the STANDARD ERROR is

$$[\text{standard error}] = \frac{\sqrt{2(N-1)}}{N}. \quad (51)$$

The CUMULANT-GENERATING FUNCTION for a Gaussian distribution is

$$K(h) = \ln(e^{\nu_1 h} e^{\sigma^2 h^2/2}) = \nu_1 h + \frac{1}{2}\sigma^2 h^2, \quad (52)$$

so

$$\kappa_1 = \nu_1 \quad (53)$$

$$\kappa_2 = \sigma^2 \quad (54)$$

$$\kappa_r = 0 \quad \text{for } r > 2. \quad (55)$$

For Gaussian variates,  $\kappa_r = 0$  for  $r > 2$ , so the variance of  $k$ -STATISTIC  $k_3$  is

$$\begin{aligned}
\text{var}(k_3) &= \frac{\kappa_6}{N} + \frac{9\kappa_2\kappa_4}{N-1} + \frac{9\kappa_3^2}{N-1} + \frac{6\kappa_2^3}{N(N-1)(N-2)} \\
&= \frac{6\kappa_2^3}{N(N-1)(N-2)}. \quad (56)
\end{aligned}$$

Also,

$$\text{var}(k_4) = \frac{24\kappa_2^4 N(N-1)^2}{(N-3)(N-2)(N+3)(N+5)} \quad (57)$$

$$\text{var}(g_1) = \frac{6N(N-1)}{(N-2)(N+1)(N+3)} \quad (58)$$

$$\text{var}(g_2) = \frac{24N(N-1)^2}{(N-3)(N-2)(N+3)(N+5)}, \quad (59)$$

where

$$g_1 \equiv \frac{k_3}{k_2^{3/2}} \quad (60)$$

$$g_2 \equiv \frac{k_4}{k_2^2}. \quad (61)$$

If  $P(x)$  is a Gaussian distribution, then

$$D(x) = \frac{1}{2} \left[ 1 + \text{erf} \left( \frac{x - \mu}{\sigma\sqrt{2}} \right) \right], \quad (62)$$

so variates  $x_i$  with a Gaussian distribution can be generated from variates  $y_i$  having a UNIFORM DISTRIBUTION in (0,1) via

$$x_i = \sigma\sqrt{2} \text{erf}^{-1}(2y_i - 1) + \mu. \quad (63)$$

However, a simpler way to obtain numbers with a Gaussian distribution is to use the BOX-MULLER TRANSFORMATION.

The Gaussian distribution is an approximation to the BINOMIAL DISTRIBUTION in the limit of large numbers,

$$P(n_1) = \frac{1}{\sqrt{2\pi Npq}} \exp \left[ -\frac{(n_1 - Np)^2}{2Npq} \right], \quad (64)$$

where  $n_1$  is the number of steps in the POSITIVE direction,  $N$  is the number of trials ( $N \equiv n_1 + n_2$ ), and  $p$  and  $q$  are the probabilities of a step in the POSITIVE direction and NEGATIVE direction ( $q \equiv 1 - p$ ).

The differential equation having a Gaussian distribution as its solution is

$$\frac{dy}{dx} = \frac{y(\mu - x)}{\sigma^2}, \quad (65)$$

since

$$\frac{dy}{y} = \frac{\mu - x}{\sigma^2} dx \quad (66)$$

$$\ln \left( \frac{y}{y_0} \right) = -\frac{1}{2\sigma^2} (\mu - x)^2 \quad (67)$$

$$y = y_0 e^{-(x-\mu)^2/2\sigma^2} \quad (68)$$

This equation has been generalized to yield more complicated distributions which are named using the so-called PEARSON SYSTEM.

### Gaussian Distribution—Linear Combination of Variates

If  $x$  is NORMALLY DISTRIBUTED with MEAN  $\mu$  and VARIANCE  $\sigma^2$ , then a linear function of  $x$ ,

$$y = ax + b, \quad (1)$$

is also NORMALLY DISTRIBUTED. The new distribution has MEAN  $a\mu + b$  and VARIANCE  $a^2\sigma^2$ , as can be derived using the MOMENT-GENERATING FUNCTION

$$\begin{aligned} M(t) &= \langle e^{t(ax+b)} \rangle = e^{tb} \langle e^{atx} \rangle = e^{tb} e^{\mu at + \sigma^2 (at)^2/2} \\ &= e^{tb + \mu at + \sigma^2 a^2 t^2/2} = e^{(b+a\mu)t + a^2 \sigma^2 t^2/2}, \end{aligned} \quad (2)$$

which is of the standard form with

$$\mu' = b + a\mu \quad (3)$$

$$\sigma'^2 = a^2 \sigma^2. \quad (4)$$

For a weighted sum of independent variables

$$y \equiv \sum_{i=1}^n a_i x_i, \quad (5)$$

the expectation is given by

$$\begin{aligned} M(t) &= \langle e^{yt} \rangle = \left\langle \exp \left( t \sum_{i=1}^n a_i x_i \right) \right\rangle \\ &= \langle e^{a_1 t x_1} e^{a_2 t x_2} \dots e^{a_n t x_n} \rangle \\ &= \prod_{i=1}^n \langle e^{a_i t x_i} \rangle = \prod_{i=1}^n \exp(a_i \mu_i t + \tfrac{1}{2} a_i^2 \sigma_i^2 t^2). \end{aligned} \quad (6)$$

Setting this equal to

$$\exp(\mu t + \tfrac{1}{2} \sigma^2 t^2) \quad (7)$$

gives

$$\mu \equiv \sum_{i=1}^n a_i \mu_i \quad (8)$$

$$\sigma^2 \equiv \sum_{i=1}^n a_i^2 \sigma_i^2. \quad (9)$$

Therefore, the MEAN and VARIANCE of the weighted sums of  $n$  RANDOM VARIABLES are their weighted sums.

If  $x_i$  are INDEPENDENT and NORMALLY DISTRIBUTED with MEAN 0 and VARIANCE  $\sigma^2$ , define

$$y_i \equiv \sum_j c_{ij} x_j, \quad (10)$$

where  $c$  obeys the ORTHOGONALITY CONDITION

$$c_{ik} c_{jk} = \delta_{ij}, \quad (11)$$

with  $\delta$  the KRONECKER DELTA. Then  $y_i$  are also independent and normally distributed with MEAN 0 and VARIANCE  $\sigma^2$ .

### Gaussian Elimination

A method for solving MATRIX EQUATIONS of the form

$$Ax = b. \quad (1)$$

Starting with the system of equations

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} \\ a_{21} & a_{22} & \cdots & a_{2k} \\ \vdots & \vdots & \ddots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_k \end{bmatrix}, \quad (2)$$

compose the augmented MATRIX equation

$$\begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1k} & b_1 \\ a_{21} & a_{22} & \cdots & a_{2k} & b_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{k1} & a_{k2} & \cdots & a_{kk} & b_k \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_k \end{bmatrix}. \quad (3)$$

Then, perform MATRIX operations to put the augmented MATRIX into the form

$$\begin{bmatrix} a'_{11} & a'_{12} & \cdots & a'_{1k} & b'_1 \\ 0 & a'_{22} & \cdots & a'_{2k} & b'_2 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & a'_{kk} & b'_k \end{bmatrix} \begin{bmatrix} x'_1 \\ x'_2 \\ \vdots \\ x'_k \end{bmatrix}. \quad (4)$$

Solve for  $a'_{kk}$ , then substitute back in to obtain solutions for  $n = 1, 2, \dots, k-1$ ,

$$x_i = \frac{1}{a'_{ii}} \left( b'_i - \sum_{j=i+1}^k a'_{ij} x'_j \right). \quad (5)$$

see also GAUSS-JORDAN ELIMINATION, LU DECOMPOSITION, MATRIX EQUATION, SQUARE ROOT METHOD

## Gaussian Function

In 1-D, the Gaussian function is the function from the GAUSSIAN DISTRIBUTION,

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/2\sigma^2}, \quad (1)$$

sometimes also called the FREQUENCY CURVE. The FULL WIDTH AT HALF MAXIMUM (FWHM) for a Gaussian is found by finding the half-maximum points  $x_0$ . The constant scaling factor can be ignored, so we must solve

$$e^{-(x_0-\mu)^2/2\sigma^2} = \frac{1}{2} f(x_{\max}) \quad (2)$$

But  $f(x_{\max})$  occurs at  $x_{\max} = \mu$ , so

$$e^{-(x_0-\mu)^2/2\sigma^2} = \frac{1}{2} f(\mu) = \frac{1}{2}. \quad (3)$$

Solving,

$$e^{-(x_0-\mu)^2/2\sigma^2} = 2^{-1} \quad (4)$$

$$-\frac{(x_0-\mu)^2}{2\sigma^2} = -\ln 2 \quad (5)$$

$$(x_0-\mu)^2 = 2\sigma^2 \ln 2 \quad (6)$$

$$x_0 = \pm\sigma\sqrt{2\ln 2} + \mu. \quad (7)$$

The FULL WIDTH AT HALF MAXIMUM is therefore given by

$$\text{FWHM} \equiv x_+ - x_- = 2\sqrt{2\ln 2}\sigma \approx 2.3548\sigma. \quad (8)$$

In 2-D, the circular Gaussian function is the distribution function for uncorrelated variables  $x$  and  $y$  having a GAUSSIAN BIVARIATE DISTRIBUTION and equal STANDARD DEVIATION  $\sigma = \sigma_x = \sigma_y$ ,

$$f(x, y) = \frac{1}{2\pi\sigma^2} e^{-[(x-\mu_x)^2 + (y-\mu_y)^2]/2\sigma^2}. \quad (9)$$

The corresponding elliptical Gaussian function corresponding to  $\sigma_x \neq \sigma_y$  is given by

$$f(x, y) = \frac{1}{2\pi\sigma_x\sigma_y} e^{-[(x-\mu_x)^2/2\sigma_x^2 + (y-\mu_y)^2/2\sigma_y^2]}. \quad (10)$$

The above plots show the real and imaginary parts of  $(2\pi)^{-1/2} e^{-z^2}$  together with the complex absolute value  $|(2\pi)^{-1/2} e^{-z^2}|$ .

The Gaussian function can also be used as an APODIZATION FUNCTION, shown above with the corresponding INSTRUMENT FUNCTION.

The HYPERGEOMETRIC FUNCTION is also sometimes known as the Gaussian function.

### Gaussian Hypergeometric Series

see HYPERGEOMETRIC FUNCTION

### Gaussian Integer

A COMPLEX NUMBER  $a+bi$  where  $a$  and  $b$  are INTEGERS. The Gaussian integers are members of the QUADRATIC FIELD  $\mathbb{Q}(\sqrt{-1})$ . The sum, difference, and product of two Gaussian integers are Gaussian integers, but  $a+bi|c+di$  only if there is an  $e+fi$  such that

$$(a+bi)(e+fi) = (ae-bf) + (af+be)i = c+di.$$

Gaussian INTEGERS can be uniquely factored in terms of other Gaussian INTEGERS up to POWERS of  $i$  and rearrangements.

The norm of a Gaussian integer is defined by

$$n(x+iy) = x^2 + y^2.$$

GAUSSIAN PRIMES are Gaussian integers  $a+ib$  for which  $n(a+ib) = a^2 + b^2$  is PRIME and  $a$  a PRIME INTEGER  $a$  such that  $a \equiv 3 \pmod{4}$ .

1. If  $2|n(x+iy)$ , then  $1+i$  and  $1-i|x+iy$ . These factors are equivalent since  $-i(i-1) = i+1$ . For example,  $2 = (1+i)(1-i)$  is not a Gaussian prime.
2. If  $n(x+iy) \equiv 3 \pmod{4}$   $|n(x+iy)$ , then  $n(a+ib)|x+iy$ .
3. If  $n(x+iy) \equiv 1 \pmod{4}$   $|n(x+iy)$ , then  $a+ib$  or  $b+ia|x+iy$ . If both do, then  $n(a+ib)|x+iy$ .

The Gaussian primes with  $|a|, |b| \leq 5$  are given by  $-5-4i, -5-2i, -5+2i, -5+4i, -4-5i, -4-i, -4+i, -4+5i, -3-2i, -3, -3+2i, -2-5i, -2-3i, -2-i, -2+i, -2+3i, -2+5i, -1-4i, -1-2i, -1-i, -1+i, -1+2i, -1+4i, -3i, 3i, 1-4i, 1-2i, 1-i, 1+i, 1+2i, 1+4i, 2-5i, 2-3i, 2-i, 2+i, 2+3i, 2+5i, 3-2i, 3, 3+2i, 4-5i, 4-i, 4+i, 4+5i, 5-4i, 5-2i, 5+2i, 5+4i$ .

Every Gaussian integer is within  $|n|/\sqrt{2}$  of a multiple of a Gaussian integer  $n$ .

### Gaussian Integral

The Gaussian integral, also called the PROBABILITY INTEGRAL, is the integral of the 1-D Gaussian over  $(-\infty, \infty)$ . It can be computed using the trick of combining two 1-D Gaussians

$$\begin{aligned} \int_{-\infty}^{\infty} e^{-x^2} dx &= \sqrt{\left(\int_{-\infty}^{\infty} e^{-y^2} dy\right) \left(\int_{-\infty}^{\infty} e^{-x^2} dx\right)} \\ &= \sqrt{\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-(x^2+y^2)} dy dx} \end{aligned} \quad (1)$$

and switching to POLAR COORDINATES,

$$\begin{aligned} \int_{-\infty}^{\infty} e^{-x^2} dx &= \sqrt{\int_0^{2\pi} \int_0^{\infty} e^{-r^2} r dr d\theta} \\ &= \sqrt{2\pi \left[-\frac{1}{2}e^{-r^2}r\right]_0^{\infty}} = \sqrt{\pi}. \end{aligned} \quad (2)$$

However, a simple proof can also be given which does not require transformation to POLAR COORDINATES (Nicholas and Yates 1950).

The integral from 0 to a finite upper limit  $a$  can be given by the CONTINUED FRACTION

$$\int_0^a e^{-x^2} dx = \frac{\sqrt{\pi}}{2} \frac{1}{a+} \frac{2}{2a+} \frac{3}{a+} \frac{4}{2a+} \dots \quad (3)$$

The general class of integrals of the form

$$I_n(a) \equiv \int_0^{\infty} e^{-ax^2} x^n dx \quad (4)$$

can be solved analytically by setting

$$x \equiv a^{-1/2} y \quad (5)$$

$$dx = a^{-1/2} dy \quad (6)$$

$$y^2 = ax^2. \quad (7)$$

Then

$$\begin{aligned} I_n(a) &= a^{-1/2} \int_0^{\infty} e^{-y^2} (a^{-1/2})^n dy \\ &= a^{-(1+n)/2} \int_0^{\infty} e^{-y^2} y^n dy. \end{aligned} \quad (8)$$

For  $n=0$ , this is just the usual Gaussian integral, so

$$I_0(a) = \frac{\sqrt{\pi}}{2} a^{-1/2} = \frac{1}{2} \sqrt{\frac{\pi}{a}}. \quad (9)$$

For  $n=1$ , the integrand is integrable by quadrature,

$$I_1(a) = a^{-1} \int_0^{\infty} e^{-y^2} y dy = a^{-1} \left[-\frac{1}{2}e^{-y^2}\right]_0^{\infty} = \frac{1}{2}a^{-1}. \quad (10)$$

To compute  $I_n(a)$  for  $n > 1$ , use the identity

$$\begin{aligned} -\frac{\partial}{\partial a} I_{n-2}(a) &= -\frac{\partial}{\partial a} \int_0^\infty e^{-ax^2} x^{n-2} dx \\ &= -\int_0^\infty -x^2 e^{-ax^2} x^{n-2} dx \\ &= \int_0^\infty e^{-ax^2} x^n dx = I_n(a). \end{aligned} \quad (11)$$

For  $n = 2s$  EVEN,

$$\begin{aligned} I_n(a) &= \left(-\frac{\partial}{\partial a}\right) I_{n-2}(a) = \left(-\frac{\partial}{\partial a}\right)^2 I_{n-4} \\ &= \dots = \left(-\frac{\partial}{\partial a}\right)^{n/2} I_0(a) \\ &= \frac{\partial^{n/2}}{\partial a^{n/2}} I_0(a) = \frac{\sqrt{\pi}}{2} \frac{\partial^{n/2}}{\partial a^{n/2}} a^{-1/2}, \end{aligned} \quad (12)$$

so

$$\int_0^\infty x^{2s} e^{-ax^2} dx = \frac{(s - \frac{1}{2})!}{2a^{s+1/2}} = \frac{(2s-1)!!}{2^{s+1}a^s} \sqrt{\frac{\pi}{a}}. \quad (13)$$

If  $n = 2s + 1$  is ODD, then

$$\begin{aligned} I_n(a) &= \left(-\frac{\partial}{\partial a}\right) I_{n-2}(a) = \left(-\frac{\partial}{\partial a}\right)^2 I_{n-4}(a) \\ &= \dots = \left(-\frac{\partial}{\partial a}\right)^{(n-1)/2} I_1(a) \\ &= \frac{\partial^{(n-1)/2}}{\partial a^{(n-1)/2}} I_1(a) = \frac{1}{2} \frac{\partial^{(n-1)/2}}{\partial a^{(n-1)/2}} a^{-1}, \end{aligned} \quad (14)$$

so

$$\int_0^\infty x^{2s+1} e^{-ax^2} dx = \frac{s!}{2a^{s+1}}. \quad (15)$$

The solution is therefore

$$\int_0^\infty e^{-ax^2} x^n dx = \begin{cases} \frac{(n-1)!!}{2^{n/2+1}a^{n/2}} \sqrt{\frac{\pi}{a}} & \text{for } n \text{ even} \\ \frac{[(n+1)/2]!}{2a^{(n+1)/2}} & \text{for } n \text{ odd.} \end{cases} \quad (16)$$

The first few values are therefore

$$I_0(a) = \frac{1}{2} \sqrt{\frac{\pi}{a}} \quad (17)$$

$$I_1(a) = \frac{1}{2a} \quad (18)$$

$$I_2(a) = \frac{1}{4a} \sqrt{\frac{\pi}{a}} \quad (19)$$

$$I_3(a) = \frac{1}{2a^2} \quad (20)$$

$$I_4(a) = \frac{3}{8a^2} \sqrt{\frac{\pi}{a}} \quad (21)$$

$$I_5(a) = \frac{1}{a^3} \quad (22)$$

$$I_6(a) = \frac{15}{16a^3} \sqrt{\frac{\pi}{a}}. \quad (23)$$

A related, often useful integral is

$$H_n(a) \equiv \frac{1}{\sqrt{\pi}} \int_{-\infty}^{\infty} e^{-ax^2} x^n dx, \quad (24)$$

which is simply given by

$$H_n = \begin{cases} \frac{2I_n(a)}{\sqrt{\pi}} & \text{for } n \text{ even} \\ 0 & \text{for } n \text{ odd.} \end{cases} \quad (25)$$

### Gaussian Integral (Linking Number)

see LINKING NUMBER

### Gaussian Joint Variable Theorem

Also called the MULTIVARIATE THEOREM. Given an EVEN number of variates from a NORMAL DISTRIBUTION with MEANS all 0,

$$\langle x_1 x_2 \rangle = \langle x_1 \rangle \langle x_2 \rangle, \quad (1)$$

$$\begin{aligned} \langle x_1 x_2 x_3 x_4 \rangle &= \langle x_1 x_2 \rangle \langle x_3 x_4 \rangle + \langle x_1 x_3 \rangle \langle x_2 x_4 \rangle + \langle x_1 x_4 \rangle \langle x_2 x_3 \rangle, \end{aligned} \quad (2)$$

etc. Given an ODD number of variates,

$$\langle x_1 \rangle = 0, \quad (3)$$

$$\langle x_1 x_2 x_3 \rangle = 0, \quad (4)$$

etc.

### Gaussian Mountain Range

see CAROTID-KUNDALINI FUNCTION

### Gaussian Multivariate Distribution

see also GAUSSIAN BIVARIATE DISTRIBUTION, JOINT THEOREM, MULTIVARIATE THEOREM

### Gaussian Polynomial

Defined by

$$[l] \equiv \frac{1 - q^l}{1 - q} \quad (1)$$

for integral  $l$ , and

$$\begin{bmatrix} n \\ k \end{bmatrix} \equiv \begin{cases} \prod_{l=1}^k \frac{[n-l+1]}{[l]} & \text{for } 0 \leq k \leq n \\ 0 & \text{otherwise.} \end{cases} \quad (2)$$

Unfortunately, the NOTATION conflicts with that of GAUSSIAN BRACKETS and the NEAREST INTEGER

FUNCTION. GAUSSIAN POLYNOMIALS satisfy the identities

$$\frac{\begin{bmatrix} n+1 \\ k+1 \end{bmatrix}}{\begin{bmatrix} n \\ k+1 \end{bmatrix}} = \frac{1 - q^{n+1}}{1 - q^{n-k}} \quad (3)$$

$$\frac{\begin{bmatrix} n+1 \\ k+1 \end{bmatrix}}{\begin{bmatrix} n+1 \\ k \end{bmatrix}} = \frac{1 - q^{n-k+1}}{1 - q^{k+1}}. \quad (4)$$

For  $q = 1$ , the Gaussian polynomial turns into the BINOMIAL COEFFICIENT.

see also BINOMIAL COEFFICIENT, GAUSSIAN COEFFICIENT,  $q$ -SERIES

### Gaussian Prime

Gaussian primes are GAUSSIAN INTEGERS  $a + ib$  for which  $n(a + ib) = a^2 + b^2$  is PRIME and  $a$  a PRIME INTEGER  $a$  such that  $a \equiv 3 \pmod{4}$ . The above plot of the COMPLEX PLANE shows the Gaussian primes as filled squares.

see also EISENSTEIN INTEGER, GAUSSIAN INTEGER

### Gaussian Quadrature

Seeks to obtain the best numerical estimate of an integral by picking optimal ABSCISSAS  $x_i$  at which to evaluate the function  $f(x)$ . The FUNDAMENTAL THEOREM OF GAUSSIAN QUADRATURE states that the optimal ABSCISSAS of the  $m$ -point GAUSSIAN QUADRATURE FORMULAS are precisely the roots of the orthogonal POLYNOMIAL for the same interval and WEIGHTING FUNCTION. Gaussian quadrature is optimal because it fits all POLYNOMIALS up to degree  $2m$  exactly. Slightly less optimal fits are obtained from RADAU QUADRATURE and LAGUERRE QUADRATURE.

$W(x)$	Interval	$x_i$ Are Roots Of
1	$(-1, 1)$	$P_n(x)$
$e^{-t}$	$(0, \infty)$	$L_n(x)$
$e^{-t^2}$	$(-\infty, \infty)$	$H_n(x)$
$(1 - t^2)^{-1/2}$	$(-1, 1)$	$T_n(x)$
$(1 - t^2)^{1/2}$	$(-1, 1)$	$U_n(x)$
$x^{1/2}$	$(0, 1)$	$x^{-1/2} P_{2n+1}(\sqrt{x})$
$x^{-1/2}$	$(0, 1)$	$P_n(\sqrt{x})$

To determine the weights corresponding to the Gaussian ABSCISSAS, compute a LAGRANGE INTERPOLATING POLYNOMIAL for  $f(x)$  by letting

$$\pi(x) \equiv \prod_{j=1}^m (x - x_j) \quad (1)$$

(where Chandrasekhar 1967 uses  $F$  instead of  $\pi$ ), so

$$\pi'(x_j) = \left[ \frac{d\pi}{dx} \right]_{x=x_j} = \prod_{\substack{i=1 \\ i \neq j}}^m (x_j - x_i). \quad (2)$$

Then fitting a LAGRANGE INTERPOLATING POLYNOMIAL through the  $m$  points gives

$$\phi(x) = \sum_{j=1}^m \frac{\pi(x)}{(x - x_j)\pi'(x_j)} f(x_j) \quad (3)$$

for arbitrary points  $x_i$ . We are therefore looking for a set of points  $x_j$  and weights  $w_j$  such that for a WEIGHTING FUNCTION  $W(x)$ ,

$$\begin{aligned} \int_a^b \phi(x) W(x) dx &= \int_a^b \sum_{j=1}^m \frac{\pi(x) W(x)}{(x - x_j)\pi'(x_j)} dx f(x_j) \\ &\equiv \sum_{j=1}^m w_j f(x_j), \end{aligned} \quad (4)$$

with WEIGHT

$$w_j = \frac{1}{\pi'(x_j)} \int_a^b \frac{\pi(x) W(x)}{x - x_j} dx. \quad (5)$$

The weights  $w_j$  are sometimes also called the CHRISTOFFEL NUMBER (Chandrasekhar 1967). For orthogonal POLYNOMIALS  $\phi_j(x)$  with  $j=1, \dots, n$ ,

$$\phi_j(x) = A_j \pi(x) \quad (6)$$

(Hildebrand 1956, p. 322), where  $A_n$  is the COEFFICIENT of  $x^n$  in  $\phi_n(x)$ , then

$$\begin{aligned} w_j &= \frac{1}{\phi'_n(x_j)} \int_a^b W(x) \frac{\phi(x)}{x - x_j} dx \\ &= -\frac{A_{n+1} \gamma_n}{A_n \phi'_n(x_j) \phi_{n+1}(x)}, \end{aligned} \quad (7)$$

where

$$\gamma_m \equiv \int [\phi_m(x)]^2 W(x) dx. \quad (8)$$

Using the relationship

$$\phi_{n+1}(x_i) = -\frac{A_{n+1}A_{n-1}}{A_n^2} \frac{\gamma_n}{\gamma_{n-1}} \phi_{n-1}(x_i) \quad (9)$$

(Hildebrand 1956, p. 323) gives

$$w_j = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{\phi'_n(x_j)\phi_{n-1}(x_j)}. \quad (10)$$

(Note that Press *et al.* 1992 omit the factor  $A_n/A_{n-1}$ .) In Gaussian quadrature, the weights are all POSITIVE. The error is given by

$$E_n = \frac{f^{(2n)}(\xi)}{(2n)!} \int_a^b W(x) [\pi(x)]^2 dx = \frac{\gamma_n}{A_n^2} \frac{f^{(2n)}(\xi)}{(2n)!}, \quad (11)$$

where  $a < \xi < b$  (Hildebrand 1956, pp. 320–321).

Other curious identities are

$$\begin{aligned} \sum_{k=0}^m \frac{[\phi_k(x)]^2}{\gamma_k} \\ = \frac{A_m}{A_{m+1}\gamma_m} [\phi'_{m+1}(x)\phi_m(x) - \phi'_m(x)\phi_{m+1}(x)] \end{aligned} \quad (12)$$

and

$$\sum_{k=0}^m \frac{[\phi_k(x)]^2}{\gamma_k} = -\frac{A_m\phi'_m(x_i)\phi_{m+1}(x_i)}{A_{m+1}\gamma_m} = \frac{1}{w_i} \quad (13)$$

(Hildebrand 1956, p. 323).

In the NOTATION of Szegő (1975), let  $x_{1n} < \dots < x_{nn}$  be an ordered set of points in  $[a, b]$ , and let  $\lambda_{1n}, \dots, \lambda_{nn}$  be a set of REAL NUMBERS. If  $f(x)$  is an arbitrary function on the CLOSED INTERVAL  $[a, b]$ , write the MECHANICAL QUADRATURE as

$$Q_n(f) = \sum_{\nu=1}^n \lambda_{\nu n} f(x_{\nu n}). \quad (14)$$

Here  $x_{\nu n}$  are the ABSCISSAS and  $\lambda_{\nu n}$  are the COTES NUMBERS.

#### Gaussian Sum

$$S(p, q) \equiv \sum_{r=0}^{q-1} e^{-\pi i r^2 p/q}, \quad (1)$$

where  $p$  and  $q$  are RELATIVELY PRIME INTEGERS. If  $(n, n') = 1$ , then

$$S(m, nn') = S(mn', n)S(mn, n'). \quad (2)$$

Gauss showed

$$\sum_{r=0}^{q-1} e^{2\pi i r^2/q} = \frac{1-i^q}{1-i} \sqrt{q} \quad (3)$$

for ODD  $q$ . A more general result was obtained by Schaar. For  $p$  and  $q$  of opposite PARITY (i.e., one is EVEN and the other is ODD), SCHAAR'S IDENTITY states

$$\frac{1}{\sqrt{q}} \sum_{r=0}^{q-1} e^{-\pi i r^2 p/q} = \frac{e^{-\pi i/4}}{\sqrt{p}} \sum_{r=0}^{p-1} e^{\pi i r^2 q/p}. \quad (4)$$

Such sums are important in the theory of QUADRATIC RESIDUES.

### Generalized Fibonacci Number

A generalization of the FIBONACCI NUMBERS defined by  $1 = G_1 = G_2 = \dots = G_{c-1}$  and the RECURRENCE RELATION

$$G_n = G_{n-1} + G_{n-c}. \quad (1)$$

These are the sums of elements on successive diagonals of a left-justified PASCAL'S TRIANGLE beginning in the left-most column and moving in steps of  $c-1$  up and 1 right. The case  $c = 2$  equals the usual FIBONACCI NUMBER. These numbers satisfy the identities

$$G_1 + G_2 + G_3 + \dots + G_n = G_{n+3} - 1 \quad (2)$$

$$G_3 + G_6 + G_9 + \dots + G_{3k} = G_{3k+1} - 1 \quad (3)$$

$$G_1 + G_4 + G_7 + \dots + G_{3k+1} = G_{3k+2} \quad (4)$$

$$G_2 + G_5 + G_8 + \dots + G_{3k+2} = G_{3k+3} \quad (5)$$

(Bicknell-Johnson and Spears 1996). For the special case  $c = 3$ ,

$$G_{n+w} = G_{w-2}G_n + G_{w-3}G_{n+1} + G_{w-1}G_{n+2}. \quad (6)$$

Bicknell-Johnson and Spears (1996) give many further identities.

Horadam (1965) defined the generalized Fibonacci numbers  $\{w_n\}$  as  $w_n = w_n(a, b; p, q)$ , where  $a, b, p$ , and  $q$  are INTEGERS,  $w_0 = a$ ,  $w_1 = b$ , and  $w_n = pw_{n-1} - qw_{n-2}$  for  $n \geq 2$ . They satisfy the identities

$$w_n w_{n+2r} - eq^n U_r = w_{n+r}^2 \quad (7)$$

$$4w_n w_{n+1}^2 w_{n+2} + (w_n q^n)^2 = (w_n w_{n+2} + w_{n+1}^2)^2 \quad (8)$$

$$w_n w_{n+1} w_{n+3} w_{n+4} = w_{n+2}^4 + eq^n (p^2 + q) w_{n+2}^2 + e^2 q^{2n+1} p^2 \quad (9)$$

$$4w_n w_{n+1} w_{n+2} w_{n+4} w_{n+5} w_{n+6} + e^2 q^{2n} (w_n U_4 U_5 - w_{n+1} U_2 U_6 - w_n U_1 U_8)^2 = (w_{n+1} w_{n+2} w_{n+6} + w_n w_{n+4} w_{n+5})^2, \quad (10)$$

where

$$e \equiv pab - qa^2 - b^2 \quad (11)$$

$$U_n = w_n(0, 1; p, q). \quad (12)$$

The final above result is due to Morgado (1987) and is called the MORGADO IDENTITY.

Another generalization of the Fibonacci numbers is denoted  $x_n$ . Given  $x_1$  and  $x_2$ , define the generalized Fibonacci number by  $x_n \equiv x_{n-2} + x_{n-1}$  for  $n \geq 3$ ,

$$\sum_{i=1}^n x_n = x_{n+2} - x_2 \quad (13)$$

$$\sum_{i=1}^{10} x_n = 11x_7 \quad (14)$$

$$x_n^2 - x_{n-1}x_{n+2} = (-1)^n(x_2^2 - x_1^2 - x_1x_2), \quad (15)$$

where the plus and minus signs alternate.

### Generalized Function

The class of all regular sequences of PARTICULARLY WELL-BEHAVED FUNCTIONS equivalent to a given regular sequence (sometimes also called a DISTRIBUTION or FUNCTIONAL). A generalized function  $p(x)$  has the properties

$$\int_{-\infty}^{\infty} p'(x)f(x) dx = - \int_{-\infty}^{\infty} p(x)f'(x) dx$$

$$\int_{-\infty}^{\infty} p^{(n)}(x)f(x) dx = (-1)^n \int_{-\infty}^{\infty} p(x)f^{(n)}(x) dx.$$

The DELTA FUNCTION is a generalized function.

see also DELTA FUNCTION

### Generalized Helicoid

The SURFACE generated by a twisted curve  $C$  when rotated about a fixed axis  $A$  and, at the same time, displaced PARALLEL to  $A$  so that the velocity of displacement is always proportional to the ANGULAR VELOCITY of ROTATION.

### Generalized Helix

The GEODESICS on a general cylinder generated by lines PARALLEL to a line  $l$  with which the TANGENT makes a constant ANGLE.

see also HELIX

### Generalized Hyperbolic Functions

In 1757, V. Riccati first recorded the generalizations of the HYPERBOLIC FUNCTIONS defined by

$$F_{n,r}^{\alpha}(x) \equiv C \sum_{k=0}^{\infty} \frac{\alpha^k}{(nk+r)!} x^{nk+r}, \quad (1)$$

for  $r = 0, \dots, n-1$ , where  $\alpha$  is COMPLEX, and where the normalization is taken so that

$$F_{n,0}^{\alpha}(0) = 1. \quad (2)$$

This is called the  $\alpha$ -hyperbolic function of order  $n$  of the  $k$ th kind. The functions  $F_{n,r}^{\alpha}$  satisfy

$$F_{n,r}^{\alpha}(x) = (\sqrt[n]{\alpha})^{-r} (\sqrt[n]{\alpha} x) \quad (3)$$

and

$$f^{(k)}(x) = \alpha f(x), \quad (4)$$

where

$$f^{(k)}(0) = \begin{cases} 0 & k \neq r, 0 \leq k \leq n-1, \\ 1 & k = r. \end{cases} \quad (5)$$

In addition,

$$\frac{d}{dx} F_{n,r}^{\alpha}(x) = \begin{cases} F_{n,r-1}^{\alpha}(x) & \text{for } 0 < r \leq n-1 \\ \alpha F_{n,n-1}^{\alpha}(x) & \text{for } r = 0. \end{cases} \quad (6)$$

The functions give a generalized EULER FORMULA

$$e^{\sqrt[n]{\alpha} x} = \sum_{r=0}^{n-1} (\sqrt[n]{\alpha})^r F_{n,r}^{\alpha}(x). \quad (7)$$

Since there are  $n$   $n$ th roots of  $\alpha$ , this gives a system of  $n$  linear equations. Solving for  $F_{n,r}^{\alpha}$  gives

$$F_{n,r}^{\alpha}(x) = \frac{1}{n} (\sqrt[n]{\alpha})^{-r} \sum_{k=0}^{n-1} \omega_n^{-rk} \exp(\omega_n^k \sqrt[n]{\alpha} x), \quad (8)$$

where

$$\omega_n = \exp\left(\frac{2\pi i}{n}\right) \quad (9)$$

is a PRIMITIVE ROOT OF UNITY.

The LAPLACE TRANSFORM is

$$\int_0^{\infty} e^{-st} F_{n,r}^{\alpha}(at) dt = \frac{s^{n-r-1} a^r}{s^n + \alpha a_n}. \quad (10)$$

The generalized hyperbolic function is also related to the MITTAG-LEFFLER FUNCTION  $E_\gamma(x)$  by

$$F_{n,0}^1(x) = E_n(x^n). \quad (11)$$

The values  $n = 1$  and  $n = 2$  give the exponential and circular/hyperbolic functions (depending on the sign of  $\alpha$ ), respectively.

$$F_{1,0}^\alpha(x) = e^{\alpha x} \quad (12)$$

$$F_{2,0}^\alpha(x) = \cosh(\sqrt{\alpha}x) \quad (13)$$

$$F_{2,1}^\alpha(x) = \frac{\sinh(\sqrt{\alpha}x)}{\sqrt{\alpha}}. \quad (14)$$

For  $\alpha = 1$ , the first few functions are

$$F_{1,0}^1(x) = e^x$$

$$F_{2,0}^1(x) = \cosh x$$

$$F_{2,1}^1(x) = \sinh x$$

$$F_{3,0}^1(x) = \frac{1}{3}[e^x + 2e^{-x/2} \cos(\frac{1}{2}\sqrt{3}x)]$$

$$F_{3,1}^1(x) = \frac{1}{3}[e^x + 2e^{-x/2} \cos(\frac{1}{2}\sqrt{3}x + \frac{1}{3}\pi)]$$

$$F_{3,2}^1(x) = \frac{1}{3}[e^x + 2e^{-x/2} \cos(\frac{1}{2}\sqrt{3}x - \frac{1}{3}\pi)]$$

$$F_{4,0}^1(x) = \frac{1}{2}(\cosh x + \cos x)$$

$$F_{4,1}^1(x) = \frac{1}{2}(\sinh x + \sin x)$$

$$F_{4,2}^1(x) = \frac{1}{2}(\cosh x - \cos x)$$

$$F_{4,3}^1(x) = \frac{1}{2}(\sinh x - \sin x).$$

### Generalized Hypergeometric Function

The generalized hypergeometric function is given by a HYPERGEOMETRIC SERIES, i.e., a series for which the ratio of successive terms can be written

$$\frac{a_{k+1}}{a_k} = \frac{P(k)}{Q(k)} = \frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)}x. \quad (1)$$

(The factor of  $k+1$  in the DENOMINATOR is present for historical reasons of notation.) The resulting generalized hypergeometric function is written

$$\sum_{k=0}^{\infty} a_k x^k = {}_pF_q \left[ \begin{matrix} a_1, a_2, \dots, a_p \\ b_1, b_2, \dots, b_q \end{matrix} ; x \right] \quad (2)$$

$$= \sum_{k=0}^{\infty} \frac{(a_1)_k (a_2)_k \cdots (a_p)_k}{(b_1)_k (b_2)_k \cdots (b_q)_k} \frac{x^k}{k!}, \quad (3)$$

where  $(a)_k$  is the POCHHAMMER SYMBOL or RISING FACTORIAL

$$(a)_k \equiv \frac{\Gamma(a+k)}{\Gamma(a)} = a(a+1)\cdots(a+k-1). \quad (4)$$

If the argument  $x = 1$ , then the function is abbreviated

$${}_pF_q \left[ \begin{matrix} a_1, a_2, \dots, a_p \\ b_1, b_2, \dots, b_q \end{matrix} ; x \right] \equiv {}_pF_q \left[ \begin{matrix} a_1, a_2, \dots, a_p \\ b_1, b_2, \dots, b_q \end{matrix} ; x \right]. \quad (5)$$

${}_2F_1(a, b; c; z)$  is "the" HYPERGEOMETRIC FUNCTION, and  ${}_1F_1(a; b; z) \equiv M(z)$  is the CONFLUENT HYPERGEOMETRIC FUNCTION. A function of the form  ${}_0F_1(; b; z)$  is called a CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION.

The generalized hypergeometric function

$${}_{p+1}F_p \left[ \begin{matrix} a_1, a_2, \dots, a_{p+1} \\ b_1, b_2, \dots, b_p \end{matrix} ; z \right] \quad (6)$$

is a solution to the DIFFERENTIAL EQUATION

$$[\vartheta(\vartheta+b-1)\cdots(\vartheta+b_p-1) - z(\vartheta+a_1)(\vartheta+a_2)\cdots(\vartheta+a_{p+1})]y = 0, \quad (7)$$

where

$$\vartheta = z \frac{d}{dz}. \quad (8)$$

The other linearly independent solution is

$$z^{1-b_1} {}_{p+1}F_p \left[ \begin{matrix} 1+a_1-b_1, 1+a_2-b_2, \\ \dots, 1+a_{p+1}-b_1 \\ 2-b_1, 1-b_2-b_1, \dots, \\ 1-b_p-b_1 \end{matrix} ; z \right]. \quad (9)$$

A generalized hypergeometric equation is termed "well posed" if

$$1+a_1=b_1+a_2=\dots=b_p+a_{p+1}. \quad (10)$$

Many sums can be written as generalized hypergeometric functions by inspection of the ratios of consecutive terms in the generating HYPERGEOMETRIC SERIES. For example, for

$$f(n) \equiv \sum_k (-1)^k \binom{2n}{k}^2, \quad (11)$$

the ratio of successive terms is

$$\frac{a_{k+1}}{a_k} = \frac{(-1)^{k+1} \binom{2n}{k+1}^2}{(-1)^k \binom{2n}{k}^2} = -\frac{(k-2n)^2}{(k+1)^2}, \quad (12)$$

yielding

$$f(n) = {}_2F_1 \left[ \begin{matrix} -2n, -2n \\ 1 \end{matrix}; -1 \right] = {}_2F_1(-2n, -2n; 1; -1) \quad (13)$$

(Petkovšek 1996, pp. 44–45).

Gosper (1978) discovered a slew unusual hypergeometric function identities, many of which were subsequently proven by Gessel and Stanton (1982). An important generalization of Gosper's technique, called ZEILBERGER'S ALGORITHM, in turn led to the powerful machinery of the WILF-ZEILBERGER PAIR (Zeilberger 1990).

Special hypergeometric identities include GAUSS'S HYPERGEOMETRIC THEOREM

$${}_2F_1(a, b; c; 1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} \quad (14)$$

for  $\Re[c-a-b] > 0$ , KUMMER'S FORMULA

$${}_2F_1(a, b; c; -1) = \frac{\Gamma(\frac{1}{2}b+1)\Gamma(b-a+1)}{\Gamma(b+1)\Gamma(\frac{1}{2}b-a+1)}, \quad (15)$$

where  $a-b+c=1$  and  $b$  is a positive integer, SAALSCHÜTZ'S THEOREM

$${}_3F_2(a, b, c; d, e; 1) = \frac{(d-a)_{|c|}(d-b)_{|c|}}{d_{|c|}(d-a-b)_{|c|}} \quad (16)$$

for  $d+e=a+b+c+1$  with  $c$  a negative integer and  $(a)_n$  the POCHHAMMER SYMBOL, DIXON'S THEOREM

$${}_3F_2(a, b, c; d, e; 1) = \frac{(\frac{1}{2}a)!(a-b)!(a-c)!(\frac{1}{2}a-b-c)!}{a!(\frac{1}{2}a-b)!(\frac{1}{2}a-c)!(a-b-c)!}, \quad (17)$$

where  $1+a/2-b-c$  has a positive REAL PART,  $d=a-b+1$ , and  $e=a-c+1$ , the CLAUSEN FORMULA

$${}_4F_3 \left[ \begin{matrix} a & b & c & d \\ e & f & g \end{matrix}; 1 \right] = \frac{(2a)_{|d|}(a+b)_{|d|}(2b)_{|d|}}{(2a+2b)_{|d|}a_{|d|}b_{|d|}}, \quad (18)$$

for  $a+b+c-d=1/2$ ,  $e=a+b+1/2$ ,  $a+f=d+1=b+g$ ,  $d$  a nonpositive integer, and the DOUGALL-RAMANUJAN IDENTITY

$$\begin{aligned} & {}_7F_6 \left[ \begin{matrix} a_1, a_2, a_3, a_4, a_5, a_6, a_7 \\ b_1, b_2, b_3, b_4, b_5, b_6 \end{matrix}; 1 \right] \\ &= \frac{(a_1+1)_n(a_1-a_2-a_3+1)_n}{(a_1-a_2+1)_n(a_1-a_3+1)_n} \\ &\quad \times \frac{(a_1-a_2-a_4+1)_n(a_1-a_3-a_4+1)_n}{(a_1-a_4+1)_n(a_1-a_2-a_3-a_4+1)_n}, \quad (19) \end{aligned}$$

where  $n=2a_1+1=a_2+a_3+a_4+a_5$ ,  $a_6=1+a_1/2$ ,  $a_7=-n$ , and  $b_i=1+a_1-a_{i+1}$  for  $i=1, 2, \dots, 6$ . For all these identities,  $(a)_n$  is the POCHHAMMER SYMBOL.

Gessel (1994) found a slew of new identities using WILF-ZEILBERGER PAIRS, including the following:

$${}_5F_4 \left[ \begin{matrix} -a-b, n+1, n+c+1, 2n-a-b+1, n+\frac{1}{2}(3-a-b) \\ n-a-b-c+1, n-a-b+1, 2n+2, n+\frac{1}{2}(1-a-b) \end{matrix}; 1 \right] = 0 \quad (20)$$

$${}_3F_2 \left[ \begin{matrix} -3n, \frac{2}{3}-c, 3n+2 \\ \frac{3}{2}, 1-3c \end{matrix}; \frac{3}{4} \right] = \frac{(c+\frac{2}{3})_n(\frac{1}{3})_n}{(1-c)_n(\frac{4}{3})_n} \quad (21)$$

$${}_3F_2 \left[ \begin{matrix} -3b, -\frac{3}{2}n, \frac{1}{2}(1-3n) \\ -3n, \frac{2}{3}-b-n \end{matrix}; \frac{4}{3} \right] = \frac{(\frac{1}{3}-b)_n}{(\frac{1}{3}+b)_n} \quad (22)$$

$${}_4F_3 \left[ \begin{matrix} \frac{3}{2}+\frac{1}{5}n, \frac{2}{3}, -n, 2n+2 \\ n+\frac{11}{6}, \frac{4}{3}, \frac{1}{5}n+\frac{1}{2} \end{matrix}; \frac{2}{27} \right] = \frac{(\frac{5}{2})_n(\frac{11}{6})_n}{(\frac{3}{2})_n(\frac{7}{2})_n} \quad (23)$$

(Petkovšek *et al.* 1996, pp. 135–137).

## Generalized Matrix Inverse

see MOORE-PENROSE GENERALIZED MATRIX INVERSE

**Generalized Mean**

A generalized version of the MEAN

$$m(t) \equiv \left( \frac{1}{n} \sum_{k=1}^n a_k^t \right)^{1/t} \quad (1)$$

with parameter  $t$  which gives the GEOMETRIC MEAN, ARITHMETIC MEAN, and HARMONIC MEAN as special cases:

$$\lim_{t \rightarrow 0} m(t) = G \quad (2)$$

$$m(1) = A \quad (3)$$

$$m(-1) = H. \quad (4)$$

see also MEAN

**Generalized Remainder Method**

An algorithm for computing a UNIT FRACTION.

**Generating Function**

A POWER SERIES

$$f(x) = \sum_{n=0}^{\infty} a_n x^n$$

whose COEFFICIENTS give the SEQUENCE  $\{a_0, a_1, \dots\}$ . The *Mathematica*® (Wolfram Research, Champaign, IL) function `DiscreteMath`RSolve`PowerSum` gives the generating function of a given expression, and `ExponentialPowerSum` gives the exponential generating function.

Generating functions for the first few powers are

$$\begin{aligned} 1: & \frac{x}{1-x} &= x + x^2 + x^3 + \dots \\ n: & \frac{x}{(1-x)^2} &= x + 2x^2 + 3x^3 + 4x^4 + \dots \\ n^2: & \frac{x(x+1)}{(1-x)^3} &= x + 4x^2 + 9x^3 + 16x^4 + \dots \\ n^3: & \frac{x(x^2+4x+1)}{(x-1)^4} &= x + 8x^2 + 27x^3 + \dots \\ n^4: & \frac{x(x+1)(x^2+10x+1)}{(x-1)^5} &= x + 16x^2 + 81x^3 + \dots \end{aligned}$$

**Generation**

In population studies, the direct offspring of a reference population (roughly) constitutes a single generation. For a CELLULAR AUTOMATON, the fundamental unit of time during which the rules of reproduction are applied once is called a generation.

**Generator (Digitadition)**

An INTEGER used to generate a DIGITADDITION. A number can have more than one generator. If a number has no generator, it is called a SELF NUMBER.

**Generator (Group)**

An element of a CYCLIC GROUP, the POWERS of which generate the entire GROUP.

**References**

Arfken, G. "Generators." §4.11 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 261–267, 1985.

**Genetic Algorithm**

An adaptive ALGORITHM involving search and optimization first used by John Holland. Holland created an electronic organism as a binary string ("chromosome"), and then used genetic and evolutionary principles of fitness-proportionate selection for reproduction (including random crossover and mutation) to search enormous solution spaces efficiently. So-called genetic programming languages apply the same principles, using an expression tree instead of a bit string as the "chromosome."

see also CELLULAR AUTOMATON

**Genocchi Number**

A number given by the GENERATING FUNCTION

$$\frac{2t}{e^t + 1} = \sum_{n=1}^{\infty} G_n \frac{t^n}{n!}.$$

It satisfies  $G_1 = 1$ ,  $G_3 = G_5 = G_7 = \dots$ , and even coefficients are given by

$$\begin{aligned} G_{2n} &= 2(1 - 2^{2n})B_{2n} \\ &= 2nE_{2n-1}(0), \end{aligned}$$

where  $B_n$  is a BERNOULLI NUMBER and  $E_n(x)$  is an EULER POLYNOMIAL. The first few Genocchi numbers for  $n$  EVEN are  $-1, 1, -3, 17, -155, 2073, \dots$  (Sloane's A001469).

**Genus (Curve)**

One of the PLÜCKER CHARACTERISTICS, defined by

$$p \equiv \frac{1}{2}(n-1)(n-2) - (\delta + \kappa) = \frac{1}{2}(m-1)(m-2) - (\tau + \iota),$$

where  $m$  is the class,  $n$  the order,  $\delta$  the number of nodes,  $\kappa$  the number of CUSPS,  $\iota$  the number of stationary tangents (INFLECTION POINTS), and  $\tau$  the number of BITANGENTS.

see also RIEMANN CURVE THEOREM

**References**

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 100, 1959.

**Genus (Knot)**

The least genus of any SEIFERT SURFACE for a given KNOT. The UNKNOT is the only KNOT with genus 0.

**Genus (Surface)**

A topologically invariant property of a surface defined as the largest number of nonintersecting simple closed curves that can be drawn on the surface without separating it. Roughly speaking, it is the number of HOLES in a surface.

see also EULER CHARACTERISTIC

**Genus Theorem**

A DIOPHANTINE EQUATION

$$x^2 + y^2 = p$$

can be solved for  $p$  a PRIME IFF  $p \equiv 1 \pmod{4}$  or  $p = 2$ . The representation is unique except for changes of sign or rearrangements of  $x$  and  $y$ .

see also COMPOSITION THEOREM, FERMAT'S THEOREM

**Geocentric Latitude**

An AUXILIARY LATITUDE given by

$$\phi_g = \tan^{-1}[(1 - e^2) \tan \phi].$$

The series expansion is

$$\phi_g = \phi - e_2 \sin(2\phi) + \frac{1}{2}e_2^2 \sin(4\phi) + \frac{1}{3}e_2^3 \sin(6\phi) + \dots,$$

where

$$e_2 \equiv \frac{e^2}{2 - e^2}.$$

see also LATITUDE

**Geodesic**

Given two points on a surface, the geodesic is defined as the shortest path on the surface connecting them. Geodesics have many interesting properties. The NORMAL VECTOR to any point of a GEODESIC arc lies along the normal to a surface at that point (Weinstock 1974, p. 65).

Furthermore, no matter how badly a SPHERE is distorted, there exist an infinite number of closed geodesics on it. This general result, demonstrated in the early 1990s, extended earlier work by Birkhoff, who proved in 1917 that there exists at least one closed geodesic on a distorted sphere, and Lyusternik and Schirelmann, who proved in 1923 that there exist at least three closed geodesics on such a sphere (Cipra 1993).

For a surface  $g(x, y, z) = 0$ , the geodesic can be found by minimizing the ARC LENGTH

$$L \equiv \int ds = \int \sqrt{dx^2 + dy^2 + dz^2}. \quad (1)$$

But

$$dx = \frac{\partial x}{\partial u} du + \frac{\partial x}{\partial v} dv \quad (2)$$

$$dx^2 = \left(\frac{\partial x}{\partial u}\right)^2 du^2 + 2 \frac{\partial x}{\partial u} \frac{\partial x}{\partial v} du dv + \left(\frac{\partial x}{\partial v}\right)^2 dv^2, \quad (3)$$

and similarly for  $dy^2$  and  $dz^2$ . Plugging in,

$$L = \int \left\{ \left[ \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2 \right] du^2 + 2 \left[ \frac{\partial x}{\partial u} \frac{\partial x}{\partial v} + \frac{\partial y}{\partial u} \frac{\partial y}{\partial v} + \frac{\partial z}{\partial u} \frac{\partial z}{\partial v} \right] du dv + \left[ \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2 \right] dv^2 \right\}^{1/2}. \quad (4)$$

This can be rewritten as

$$L = \int \sqrt{P + 2Qv' + Rv'^2} du \quad (5)$$

$$= \int \sqrt{Pu'^2 + 2Qu' + R} dv, \quad (6)$$

where

$$v' \equiv \frac{dv}{du} \quad (7)$$

$$u' \equiv \frac{du}{dv} \quad (8)$$

and

$$P \equiv \left(\frac{\partial x}{\partial u}\right)^2 + \left(\frac{\partial y}{\partial u}\right)^2 + \left(\frac{\partial z}{\partial u}\right)^2 \quad (9)$$

$$Q \equiv \frac{\partial x}{\partial u} \frac{\partial x}{\partial v} + \frac{\partial y}{\partial u} \frac{\partial y}{\partial v} + \frac{\partial z}{\partial u} \frac{\partial z}{\partial v} \quad (10)$$

$$R \equiv \left(\frac{\partial x}{\partial v}\right)^2 + \left(\frac{\partial y}{\partial v}\right)^2 + \left(\frac{\partial z}{\partial v}\right)^2. \quad (11)$$

Taking derivatives,

$$\frac{\partial L}{\partial v} = \frac{1}{2}(P + 2Qv' + Rv'^2)^{-1/2} \times \left( \frac{\partial P}{\partial v} + 2\frac{\partial Q}{\partial v}v' + \frac{\partial R}{\partial v}v'^2 \right) \quad (12)$$

$$\frac{\partial L}{\partial v'} = \frac{1}{2}(P + 2Qv' + Rv'^2)^{-1/2}(2Q + 2Rv'), \quad (13)$$

so the EULER-LAGRANGE DIFFERENTIAL EQUATION then gives

$$\frac{\partial P}{\partial v} + 2v'\frac{\partial Q}{\partial v} + v'^2\frac{\partial R}{\partial v} - \frac{d}{du} \left( \frac{Q + Rv'}{\sqrt{P + 2Qv' + Rv'^2}} \right) = 0. \quad (14)$$

In the special case when  $P$ ,  $Q$ , and  $R$  are explicit functions of  $u$  only,

$$\frac{Q + Rv'}{\sqrt{P + 2Qv' + Rv'^2}} = c_1 \quad (15)$$

$$\frac{Q^2 + 2QRv' + R^2v'^2}{P + 2Qv' + Rv'^2} = c_1^2 \quad (16)$$

$$v'^2 R(R - c_1^2) + 2v'Q(R - c_1^2) + (Q^2 - Pc_1^2) = 0 \quad (17)$$

$$v' = \frac{1}{2R(R - c_1^2)} [2Q(c_1^2 - R) \pm \sqrt{4Q^2(R - c_1^2)^2 - 4R(R - c_1^2)(Q^2 - Pc_1^2)}]. \quad (18)$$

Now, if  $P$  and  $R$  are explicit functions of  $u$  only and  $Q = 0$ ,

$$v' = \frac{\sqrt{4R(R - c_1^2)Pc_1^2}}{2R(R - c_1^2)} = c_1 \sqrt{\frac{P}{R(R - c_1^2)}}, \quad (19)$$

so

$$v = c_1 \int \sqrt{\frac{P}{R(R - c_1^2)}} du. \quad (20)$$

In the case  $Q = 0$  where  $P$  and  $R$  are explicit functions of  $v$  only, then

$$\frac{\partial P}{\partial v} + v'^2 \frac{\partial R}{\partial v} - \frac{d}{du} \left( \frac{Rv'}{\sqrt{P + Rv'^2}} \right) = 0, \quad (21)$$

so

$$\frac{\partial P}{\partial v} + v'^2 \frac{\partial R}{\partial v} - 2\sqrt{P + Rv'^2} R \times \left[ \frac{v''}{\sqrt{P + Rv'^2}} + \left(-\frac{1}{2}\right) \frac{v'(2Rv'v'')}{(P + Rv'^2)^{3/2}} \right] = 0 \quad (22)$$

$$\frac{\partial P}{\partial v} + v'^2 \frac{\partial R}{\partial v} - 2Rv'' + \frac{2R^2v'^2v''}{P + Rv'^2} = 0 \quad (23)$$

$$\frac{Rv'^2}{\sqrt{P + Rv'^2}} - \sqrt{P + Rv'^2} = c_1 \quad (24)$$

$$Rv'^2 - (P + Rv'^2) = c_1 \sqrt{P + Rv'^2} \quad (25)$$

$$\left(-\frac{P}{c_1}\right)^2 = P + Rv'^2 \quad (26)$$

$$\frac{P^2 - c_1^2 P}{Rc_1^2} = v'^2, \quad (27)$$

and

$$u = c_1 \int \sqrt{\frac{R}{P^2 - c_1^2 P}} dv. \quad (28)$$

For a surface of revolution in which  $y = g(x)$  is rotated about the  $x$ -axis so that the equation of the surface is

$$y^2 + z^2 = g^2(x), \quad (29)$$

the surface can be parameterized by

$$x = u \quad (30)$$

$$y = g(u) \cos v \quad (31)$$

$$z = g(u) \sin v. \quad (32)$$

The equation of the geodesics is then

$$v = c_1 \int \frac{\sqrt{1 + [g'(u)]^2} du}{g(u) \sqrt{[g(u)]^2 - c_1^2}}. \quad (33)$$

#### Geodesic Curvature

For a unit speed curve on a surface, the length of the surface-tangential component of acceleration is the geodesic curvature  $\kappa_g$ . Curves with  $\kappa_g = 0$  are called GEODESICS. For a curve parameterized as  $\alpha(t) = \mathbf{x}(u(t), v(t))$ , the geodesic curvature is given by

$$\kappa_g = \sqrt{EG - F^2} [ -\Gamma_{11}^2 u'^3 + \Gamma_{22}^1 v'^3 - (2\Gamma_{12}^2 - \Gamma_{11}^1) u'^2 v' + (2\Gamma_{12}^1 - \Gamma_{22}^2) u' v'^2 + u'' v' - v'' u' ],$$

where  $E$ ,  $F$ , and  $G$  are coefficients of the first FUNDAMENTAL FORM and  $\Gamma_{ij}^k$  are CHRISTOFFEL SYMBOLS OF THE SECOND KIND.

## Geodesic Dome

A TRIANGULATION of a PLATONIC SOLID or other POLYHEDRON to produce a close approximation to a SPHERE. The  $n$ th order geodesation operation replaces each polygon of the polyhedron by the projection onto the CIRCUMSPHERE of the order  $n$  regular tessellation of that polygon. The above figure shows geodesations of orders 1 to 3 (from top to bottom) of the TETRAHEDRON, CUBE, OCTAHEDRON, DODECAHEDRON, and ICOSAHEDRON (from left to right).

R. Buckminster Fuller designed the first geodesic dome (i.e., geodesation of a HEMISPHERE). Fuller's dome was constructed from an ICOSAHEDRON by adding ISOSCELES TRIANGLES about each VERTEX and slightly repositioning the VERTICES. In such domes, neither the VERTICES nor the centers of faces necessarily lie at exactly the same distances from the center. However, these conditions are approximately satisfied.

In the geodesic domes discussed by Kniffen (1994), the sum of VERTEX angles is chosen to be a constant. Given a PLATONIC SOLID, let  $e' \equiv 2e/v$  be the number of EDGES meeting at a VERTEX and  $n$  be the number of EDGES of the constituent POLYGON. Call the angle of the old VERTEX point  $A$  and the angle of the new VERTEX point  $F$ . Then

$$A = B \quad (1)$$

$$2e'A = nF \quad (2)$$

$$2A + F = 180^\circ. \quad (3)$$

Solving for  $A$  gives

$$2A + \frac{2e'}{n}A = 2A \left( 1 + \frac{e'}{n} \right) = 180^\circ \quad (4)$$

$$A = 90^\circ \frac{n}{e' + n}, \quad (5)$$

and

$$F = \frac{2e'}{n}A = 180^\circ \frac{e'}{e' + n}. \quad (6)$$

The VERTEX sum is

$$\Sigma = nF = 180^\circ \frac{e'n}{e' + n}. \quad (7)$$

Solid	$f$	$v$	$e'$	$n$	$A$	$F$	$\Sigma$
tetrahedron			3	3	$45^\circ$	$90^\circ$	$270^\circ$
cube	24	14	3	4	$51\frac{3}{7}^\circ$	$81\frac{3}{7}^\circ$	$308\frac{4}{7}^\circ$
octahedron			4	3	$38\frac{4}{7}^\circ$	$108\frac{4}{7}^\circ$	$308\frac{4}{7}^\circ$
dodecahedron	60	32	3	5	$56\frac{1}{4}^\circ$	$71\frac{1}{4}^\circ$	$337\frac{1}{2}^\circ$
icosahedron			5	3	$33\frac{3}{4}^\circ$	$118\frac{3}{4}^\circ$	$337\frac{1}{2}^\circ$

## Geometric Construction

In antiquity, geometric constructions of figures and lengths were restricted to use of only a STRAIGHTEDGE and COMPASS. Although the term "RULER" is sometimes used instead of "STRAIGHTEDGE," no markings which could be used to make measurements were allowed according to the Greek prescription. Furthermore, the "COMPASS" could not even be used to mark off distances by setting it and then "walking" it along, so the COMPASS had to be considered to automatically collapse when not in the process of drawing a CIRCLE.

Because of the prominent place Greek geometric constructions held in Euclid's *Elements*, these constructions

are sometimes also known as EUCLIDEAN CONSTRUCTIONS. Such constructions lay at the heart of the GEOMETRIC PROBLEMS OF ANTIQUITY of CIRCLE SQUARING, CUBE DUPLICATION, and TRISECTION of an ANGLE. The Greeks were unable to solve these problems, but it was not until hundreds of years later that the problems were proved to be actually impossible under the limitations imposed.

Simple algebraic operations such as  $a + b$ ,  $a - b$ ,  $ra$  (for  $r$  a RATIONAL NUMBER),  $a/b$ ,  $ab$ , and  $\sqrt{x}$  can be performed using geometric constructions (Courant and Robbins 1996). Other more complicated constructions, such as the solution of APOLLONIUS' PROBLEM and the construction of INVERSE POINTS can also be accomplished.

One of the simplest geometric constructions is the construction of a BISECTOR of a LINE SEGMENT, illustrated above.

The Greeks were very adept at constructing POLYGONS, but it took the genius of Gauss to mathematically determine which constructions were possible and which were not. As a result, Gauss determined that a series of POLYGONS (the smallest of which has 17 sides; the HEPTADECAGON) had constructions unknown to the Greeks. Gauss showed that the CONSTRUCTIBLE POLYGONS (several of which are illustrated above) were closely related to numbers called the FERMAT PRIMES.

Wernick (1982) gave a list of 139 sets of three located points from which a TRIANGLE was to be constructed. Of Wernick's original list of 139 problems, 20 had not yet been solved as of 1996 (Meyers 1996).

It is possible to construct RATIONAL NUMBERS and EUCLIDEAN NUMBERS using a STRAIGHTEDGE and COMPASS construction. In general, the term for a number which can be constructed using a COMPASS and STRAIGHTEDGE is a CONSTRUCTIBLE NUMBER. Some IRRATIONAL NUMBERS, but no TRANSCENDENTAL NUMBERS, can be constructed.

It turns out that all constructions possible with a COMPASS and STRAIGHTEDGE can be done with a COMPASS alone, as long as a line is considered constructed when its two endpoints are located. The reverse is also true, since Jacob Steiner showed that all constructions possible with STRAIGHTEDGE and COMPASS can be done using only a straightedge, as long as a fixed CIRCLE and its center (or two intersecting CIRCLES without their centers, or three nonintersecting CIRCLES) have been drawn beforehand. Such a construction is known as a STEINER CONSTRUCTION.

GEOMETROGRAPHY is a quantitative measure of the simplicity of a geometric construction. It reduces geometric constructions to five types of operations, and seeks to reduce the total number of operations (called the "SIMPLICITY") needed to effect a geometric construction.

Dixon (1991, pp. 34-51) gives approximate constructions for some figures (the HEPTAGON and NONAGON) and lengths ( $P_1$ ) which cannot be rigorously constructed. Ramanujan (1913-14) and Olds (1963) give geometric constructions for  $355/113 \approx \pi$ . Gardner (1966, pp. 92-93) gives a geometric construction for

$$3 + \frac{16}{113} = 3.1415929 \dots \approx \pi.$$

Constructions for  $\pi$  are approximate (but inexact) forms of CIRCLE SQUARING.

## Geometric Distribution

A distribution such that

$$P(n) = q^{n-1}p = p(1-p)^{n-1}, \quad (1)$$

where  $q \equiv 1 - p$  and for  $n = 1, 2, \dots$ . The distribution is normalized since

$$\sum_{n=1}^{\infty} P(n) = \sum_{n=1}^{\infty} q^{n-1}p = p \sum_{n=0}^{\infty} q^n = \frac{p}{1-q} = \frac{p}{p} = 1. \quad (2)$$

The MOMENT-GENERATING FUNCTION is

$$\phi(t) = p[1 - (1-p)e^{it}]^{-1}, \quad (3)$$

or

$$\begin{aligned} M(t) &= \langle e^{tn} \rangle = \sum_{n=1}^{\infty} e^{tn} p q^{n-1} = p \sum_{n=0}^{\infty} e^{t(n+1)} q^n \\ &= p e^t \sum_{n=0}^{\infty} (e^t q)^n = \frac{p e^t}{1 - e^t q} \end{aligned} \quad (4)$$

$$\begin{aligned} M'(t) &= p \left[ \frac{(1 - e^t q) e^t - e^t (-e^t q)}{(1 - e^t q)^2} \right] \\ &= \frac{p(e^t - q e^{2t} + q e^{2t})}{(1 - e^t q)^2} = \frac{p e^t}{(1 - e^t q)^2} \end{aligned} \quad (5)$$

$$\begin{aligned} M''(t) &= p \frac{(1 - e^t q)^2 e^t - e^t 2(1 - e^t q)(-e^t q)}{(1 - e^t q)^4} \\ &= p \frac{(1 - 2e^t q + e^{2t} q^2) e^t + 2q e^{2t} (1 - e^t q)}{(1 - e^t q)^4} \\ &= p \frac{e^t - 2e^{2t} q + e^{3t} q^2 + 2q e^{2t} - 2q^2 e^{3t}}{(1 - e^t q)^4} \\ &= p \frac{e^t - q^2 e^{3t}}{(1 - e^t q)^4} = \frac{p e^t (1 - q^2 e^{2t})}{(1 - e^t q)^4} \\ &= \frac{p e^t (1 + q e^t)}{(1 - e^t q)^3} \end{aligned} \quad (6)$$

$$M'''(t) = \frac{p e^t [1 + 4e^t (1-p) + e^{2t} (1-p)^2]}{(1 - e^t + e^t p)^4}. \quad (7)$$

Therefore,

$$M'(0) = \mu'_1 = \mu = \frac{p}{(1-q)^2} = \frac{p}{p^2} = \frac{1}{p} \quad (8)$$

$$M''(0) = \mu'_2 = \frac{p(1+q)}{(1+q)^3} = \frac{p(2-p)}{p^3} = \frac{2-p}{p^2} \quad (9)$$

$$M'''(0) = \mu'_3 = \frac{(6-6p+p^2)}{p^3} \quad (10)$$

$$M^{(4)}(0) = \mu'_4 = \frac{(p-2)(-p^2+12p-12)}{p^4}, \quad (11)$$

and

$$\begin{aligned} \mu_2 &\equiv \mu'_2 - (\mu'_1)^2 = \left( \frac{2}{p^2} - \frac{1}{p} \right) - \frac{1}{p^2} = \frac{1-p}{p^2} \\ &= \frac{q}{p^2} \end{aligned} \quad (12)$$

$$\begin{aligned} \mu_3 &\equiv \mu'_3 - 3\mu'_2 \mu'_1 + 2(\mu'_1)^3 \\ &= \frac{6-6p+p^2}{p^3} - 3 \frac{2-p}{p^2} \frac{1}{p} + 2 \left( \frac{1}{p} \right)^3 \\ &= \frac{6-6p+p^2-3(2-p)+2}{p^3} \\ &= \frac{(p-1)(p-2)}{p^3} \end{aligned} \quad (13)$$

$$\begin{aligned} \mu_4 &\equiv \mu'_4 - 4\mu'_3 \mu'_1 + 6\mu'_2 (\mu'_1)^2 - 3(\mu'_1)^4 \\ &= \frac{(p-2)(-p^2+12p-12)}{p^4} - 4 \frac{6-6p+p^2}{p^3} \frac{1}{p} \\ &\quad + 6 \frac{2-p}{p^2} \left( \frac{1}{p} \right)^2 - 3 \left( \frac{1}{p} \right)^4 \\ &= \frac{(p-1)(-p^2+9p-9)}{p^4}, \end{aligned} \quad (14)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are given by

$$\mu \equiv \mu'_1 = \frac{1}{p} \quad (15)$$

$$\sigma^2 = \mu_2 = \frac{q}{p^2} \quad (16)$$

$$\begin{aligned} \gamma_1 &= \frac{\mu_3}{\sigma^3} = \frac{(p-1)(p-2)}{p^3} \left( \frac{p^2}{1-p} \right)^{3/2} \\ &= \frac{(p-1)(p-2)}{(1-p)\sqrt{1-p}} = \frac{2-p}{\sqrt{1-p}} = \frac{2-p}{\sqrt{q}} \end{aligned} \quad (17)$$

$$\begin{aligned} \gamma_2 &= \frac{\mu_4}{\sigma^4} - 3 = \frac{(p-1)(-p^2+9p-9)}{p^4 \frac{(1-p)^2}{p^4}} - 3 \\ &= \frac{-9+9p-p^2}{(p-1)} - 3 \\ &= \frac{p^2-6p+6}{1-p}. \end{aligned} \quad (18)$$

In fact, the moments of the distribution are given analytically in terms of the POLYLOGARITHM function,

$$\mu'_k \equiv \sum_{n=1}^{\infty} P(n)n^k = \sum_{n=1}^{\infty} p(1-p)^{n-1}n^k = \frac{p \operatorname{Li}_{-k}(1-p)}{1-p}. \quad (19)$$

For the case  $p = 1/2$  (corresponding to the distribution of the number of COIN TOSSES needed to win in the SAINT PETERSBURG PARADOX) this formula immediately gives

$$\mu'_1 = 2 \quad (20)$$

$$\mu'_2 = 6 \quad (21)$$

$$\mu'_3 = 26 \quad (22)$$

$$\mu'_4 = 150, \quad (23)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS in this case are

$$\mu = 2 \quad (24)$$

$$\sigma^2 = 2 \quad (25)$$

$$\gamma_1 = \frac{3}{2}\sqrt{2} \quad (26)$$

$$\gamma_2 = \frac{13}{2}. \quad (27)$$

The first CUMULANT of the geometric distribution is

$$\kappa_1 = \frac{1-p}{p}, \quad (28)$$

and subsequent CUMULANTS are given by the RECURRENT RELATION

$$\kappa_{r+1} = (1-p) \frac{d\kappa_r}{dp}. \quad (29)$$

## Geometric Mean

$$G \equiv \left( \prod_{i=1}^n a_i \right)^{1/n}.$$

Hoehn and Niven (1985) show that

$$G(a_1 + c, a_2 + c, \dots, a_n + c) > c + G(a_1, a_2, \dots, a_n)$$

for any POSITIVE constant  $c$ .

## Geometric Mean Index

The statistical INDEX

$$P_G \equiv \left[ \prod \left( \frac{p_n}{p_0} \right)^{v_0} \right]^{1/\Sigma v_0},$$

where  $p_n$  is the price per unit in period  $n$ ,  $q_n$  is the quantity produced in period  $n$ , and  $v_n \equiv p_n q_n$  the value of the  $n$  units.

## Geometric Problems of Antiquity

The Greek problems of antiquity were a set of geometric problems whose solution was sought using only COMPASS and STRAIGHTEDGE:

1. CIRCLE SQUARING.
2. CUBE DUPLICATION.
3. TRISECTION of an ANGLE.

Only in modern times, more than 2,000 years after they were formulated, were all three ancient problems proved insoluble using only COMPASS and STRAIGHTEDGE.

Another ancient geometric problem not proved impossible until 1997 is ALHAZEN'S BILLIARD PROBLEM. As Ogilvy (1990) points out, constructing the general REGULAR POLYHEDRON was really a "fourth" unsolved problem of antiquity.

see also ALHAZEN'S BILLIARD PROBLEM, CIRCLE SQUARING, COMPASS, CONSTRUCTIBLE NUMBER, CONSTRUCTIBLE POLYGON, CUBE DUPLICATION, GEOMETRIC CONSTRUCTION, REGULAR POLYHEDRON, STRAIGHTEDGE, TRISECTION

## Geometric Progression

see GEOMETRIC SEQUENCE

## Geometric Sequence

A geometric sequence is a SEQUENCE  $\{a_k\}$ ,  $k = 1, 2, \dots$ , such that each term is given by a multiple  $r$  of the previous one. Another equivalent definition is that a sequence is geometric IFF it has a zero BIAS. If the multiplier is  $r$ , then the  $k$ th term is given by

$$a_k = ra_{k-1} = r^2 a_{k-2} = a_0 r^k.$$

Without loss of generality, take  $a_0 = 1$ , giving

$$a_k = r^k.$$

## Geometric Series

A geometric series  $\sum_k a_k$  is a series for which the ratio of each two consecutive terms  $a_{k+1}/a_k$  is a constant function of the summation index  $k$ , say  $r$ . Then the terms  $a_k$  are of the form  $a_k = a_0 r^k$ , so  $a_{k+1}/a_k = r$ . If  $\{a_k\}$ , with  $k = 1, 2, \dots$ , is a GEOMETRIC SEQUENCE with multiplier  $-1 < r < 1$  and  $a_0 = 1$ , then the geometric series

$$S_n = \sum_{k=0}^n a_k = \sum_{k=0}^n r^k \quad (1)$$

is given by

$$S_n \equiv \sum_{k=0}^n r^k = 1 + r + r^2 + \dots + r^n, \quad (2)$$

so

$$rS_n = r + r^2 + r^3 + \dots + r^{n+1}. \quad (3)$$

Subtracting

$$\begin{aligned} (1-r)S_n &= (1+r+r^2+\dots+r^n) \\ &\quad - (r+r^2+r^3+\dots+r^{n+1}) \\ &= 1-r^{n+1}, \end{aligned} \quad (4)$$

so

$$S_n \equiv \sum_{k=0}^n r^k = \frac{1-r^{n+1}}{1-r}. \quad (5)$$

As  $n \rightarrow \infty$ , then

$$S \equiv S_\infty = \sum_{k=0}^{\infty} r^k = \frac{1}{1-r}. \quad (6)$$

## Geometrization Conjecture

see THURSTON'S GEOMETRIZATION CONJECTURE

## Geometrography

A quantitative measure of the simplicity of a GEOMETRIC CONSTRUCTION which reduces geometric constructions to five steps. It was devised by É. Lemoine.

- $S_1$  Place a STRAIGHTEDGE's EDGE through a given POINT,
- $S_2$  Draw a straight LINE,
- $C_1$  Place a POINT of a COMPASS on a given POINT,
- $C_2$  Place a POINT of a COMPASS on an indeterminate POINT on a LINE,
- $C_3$  Draw a CIRCLE.

Geometrography seeks to reduce the number of operations (called the "SIMPLICITY") needed to effect a construction. If the number of the above operations are denoted  $m_1, m_2, n_1, n_2$ , and  $n_3$ , respectively, then the SIMPLICITY is  $m_1 + m_2 + n_1 + n_2 + n_3$  and the symbol is  $m_1 S_1 + m_2 S_2 + n_1 C_1 + n_2 C_2 + n_3 C_3$ . It is apparently an unsolved problem to determine if a given GEOMETRIC CONSTRUCTION is of the smallest possible simplicity.

### Geometry

Geometry is the study of figures in a SPACE of a given number of dimensions and of a given type. The most common types of geometry are PLANE GEOMETRY (dealing with objects like the LINE, CIRCLE, TRIANGLE, and POLYGON), SOLID GEOMETRY (dealing with objects like the LINE, SPHERE, and POLYHEDRON), and SPHERICAL GEOMETRY (dealing with objects like the SPHERICAL TRIANGLE and SPHERICAL POLYGON).

Historically, the study of geometry proceeds from a small number of accepted truths (AXIOMS or POSTULATES), then builds up true statements using a systematic and rigorous step-by-step PROOF. However, there is much more to geometry than this relatively dry textbook approach, as evidenced by some of the beautiful and unexpected results of PROJECTIVE GEOMETRY (not to mention Schubert's powerful but questionable ENUMERATIVE GEOMETRY).

Formally, a geometry is defined as a complete locally homogeneous RIEMANNIAN METRIC. In  $\mathbb{R}^2$ , the possible geometries are Euclidean planar, hyperbolic planar, and elliptic planar. In  $\mathbb{R}^3$ , the possible geometries include Euclidean, hyperbolic, and elliptic, but also include five other types.

### Gergonne Line

The perspective line for the CONTACT TRIANGLE  $\triangle DEF$  and its TANGENTIAL TRIANGLE  $\triangle ABC$ . It is determined by the NOBBS POINTS  $D'$ ,  $E'$ , and  $F'$ . In addition to the NOBBS POINTS, the FLETCHER POINT and EVANS POINT also lie on the Gergonne line where it intersects the SODDY LINE and EULER LINE, respectively. The  $D$  and  $D'$  coordinates are given by

$$D = B + \frac{f}{e}C$$

$$D' = B - \frac{f}{e}C,$$

so  $BD CD'$  form a HARMONIC RANGE. The equation of the Gergonne line is

$$\frac{\alpha}{d} + \frac{\beta}{e} + \frac{\gamma}{f} = 0.$$

see also CONTACT TRIANGLE, EULER LINE, EVANS POINT, FLETCHER POINT, NOBBS POINTS, SODDY LINE, TANGENTIAL TRIANGLE

### References

## Gergonne Point

The common point of the CONCURRENT lines from the TANGENT points of a TRIANGLE'S INCIRCLE to the opposite VERTICES. It has TRIANGLE CENTER FUNCTION

$$\alpha = [a(b+c-a)]^{-1} = \frac{1}{2} \sec^2 A.$$

It is the ISOTOMIC CONJUGATE POINT of the NAGEL POINT. The CONTACT TRIANGLE and TANGENTIAL TRIANGLE are perspective from the Gergonne point.

## Geršgorin Circle Theorem

Gives a region in the COMPLEX PLANE containing all the EIGENVALUES of a COMPLEX SQUARE MATRIX. Let

$$|x_k| = \max\{|x_i| : 1 \leq i \leq n\} > 0 \quad (1)$$

and define

$$R_i = \sum_{\substack{j=1 \\ j \neq i}}^n |a_{ij}|. \quad (2)$$

Then each EIGENVALUE of the MATRIX  $A$  of order  $n$  is in at least one of the disks

$$\{z : |z - a_{ii}| \leq R_i\}. \quad (3)$$

The theorem can be made stronger as follows. Let  $r$  be an INTEGER with  $1 \leq r \leq n$ , then each EIGENVALUE of  $A$  is either in one of the disks  $\Gamma_1$

$$\{z : |z - a_{jj}| \leq S_j^{(r-1)}\}, \quad (4)$$

or in one of the regions

$$\left\{ z : \sum_{i=1}^r |z - a_{ii}| \leq \sum_{i=1}^r R_i \right\}, \quad (5)$$

where  $S_j^{(r-1)}$  is the sum of magnitudes of the  $r-1$  largest off-diagonal elements in column  $j$ .

## Ghost

If the sampling of an interferogram is modulated at a definite frequency instead of being uniformly sampled, spurious spectral features called "ghosts" are produced (Brault 1985). Periodic ruling or sampling errors introduce a modulation superposed on top of the expected fringe pattern due to uniform stage translation. Because modulation is a multiplicative process, spurious features are generated in spectral space at the sum and difference of the true fringe and ghost fringe frequencies, thus throwing power out of its spectral band.

Ghosts are copies of the actual spectrum, but appear at reduced strength. The above shows the power spectrum for a pure sinusoidal signal sampled by translating a Fourier transform spectrometer mirror at constant speed. The small blips on either side of the main peaks are ghosts.

In order for a ghost to appear, the process producing it must exist for most of the interferogram. However, if the ruling errors are not truly sinusoidal but vary across the length of the screw, a longer travel path can reduce their effect.

**Gigantic Prime**

A PRIME with 10,000 or more decimal digits. As of Nov. 15, 1995, 127 were known.

see also TITANIC PRIME

References

Caldwell, C. "The Ten Largest Known Primes." <http://www.utm.edu/research/primes/largest.html#largest>.

**Gilbrat's Distribution**

A CONTINUOUS DISTRIBUTION in which the LOGARITHM of a variable  $x$  has a NORMAL DISTRIBUTION,

$$P(x) = \frac{1}{\sqrt{2\pi}} e^{-(\ln x)^2/2}.$$

It is a special case of the LOG NORMAL DISTRIBUTION

$$P(x) = \frac{1}{S\sqrt{2\pi}} e^{-(\ln x - M)^2/2S^2}.$$

with  $S = 1$  and  $M = 0$ .

see also LOG NORMAL DISTRIBUTION

**Gilbreath's Conjecture**

Let the DIFFERENCE of successive PRIMES be defined by  $d_n \equiv p_{n+1} - p_n$ , and  $d_n^k$  by

$$d_n^k \equiv \begin{cases} d_n & \text{for } k = 1 \\ |d_{n+1}^{k-1} - d_n^{k-1}| & \text{for } k > 1. \end{cases}$$

N. L. Gilbreath claimed that  $d_1^k = 1$  for all  $k$  (Guy 1994). It has been verified for  $k < 63419$  and all PRIMES up to  $\pi(10^{13})$ , where  $\pi$  is the PRIME COUNTING FUNCTION.

## Gingerbreadman Map

A 2-D piecewise linear MAP defined by

$$\begin{aligned}x_{n+1} &= 1 - y_n + |x_n| \\ y_{n+1} &= x_n.\end{aligned}$$

The map is chaotic in the filled region above and stable in the six hexagonal regions. Each point in the interior hexagon defined by the vertices  $(0, 0)$ ,  $(1, 0)$ ,  $(2, 1)$ ,  $(2, 2)$ ,  $(1, 2)$ , and  $(0, 1)$  has an orbit with period six (except the point  $(1, 1)$ , which has period 1). Orbits in the other five hexagonal regions circulate from one to the other. There is a unique orbit of period five, with all others having period 30. The points having orbits of period five are  $(-1, 3)$ ,  $(-1, -1)$ ,  $(3, -1)$ ,  $(5, 3)$ , and  $(3, 5)$ , indicated in the above figure by the black line. However, there are infinitely many distinct periodic orbits which have an arbitrarily long period.

## Girth

The length of the shortest CYCLE in a GRAPH.

Girth	Example
3	tetrahedron
4	cube, $K_{3,3}$
5	Petersen graph

## Giuga's Conjecture

If  $n > 1$  and

$$n | 1^{n-1} + 2^{n-1} + \dots + (n-1)^{n-1} + 1,$$

is  $n$  necessarily a PRIME? In other words, defining

$$s_n \equiv \sum_{k=1}^{n-1} k^{n-1},$$

does there exist a COMPOSITE  $n$  such that  $s_n \equiv -1 \pmod{n}$ ? It is known that  $s_n \equiv -1 \pmod{n}$  IFF for each prime divisor  $p$  of  $n$ ,  $(p-1)|(n/p-1)$  and  $p|(n/p-1)$  (Giuga 1950, Borwein *et al.* 1996); therefore, any counterexample must be SQUAREFREE. A composite INTEGER  $n$  satisfies  $s_n \equiv -1 \pmod{n}$  IFF it is both a CARMICHAEL NUMBER and a GIUGA NUMBER. Giuga showed that there are no exceptions to the conjecture up to  $10^{1000}$ . This was later improved to  $10^{1700}$  (Bedocchi 1985) and  $10^{13800}$  (Borwein *et al.* 1996).

see also ARGOH'S CONJECTURE

## Giuga Number

Any COMPOSITE NUMBER  $n$  with  $p|(n/p-1)$  for all PRIME DIVISORS  $p$  of  $n$ .  $n$  is a Giuga number IFF

$$\sum_{k=1}^{n-1} k^{\phi(n)} \equiv -1 \pmod{n}$$

where  $\phi$  is the TOTIENT FUNCTION and IFF

$$\sum_{p|n} \frac{1}{p} - \prod_{p|n} \frac{1}{p} \in \mathbb{N}.$$

$n$  is a Giuga number IFF

$$nB_{\phi(n)} \equiv -1 \pmod{n},$$

where  $B_k$  is a BERNOULLI NUMBER and  $\phi$  is the TOTIENT FUNCTION. Every counterexample to Giuga's conjecture is a contradiction to ARGOH'S CONJECTURE and vice versa. The smallest known Giuga numbers are 30 (3 factors), 858, 1722 (4 factors), 66198 (5 factors), 2214408306, 24423128562 (6 factors), 432749205173838, 14737133470010574, 550843391309130318 (7 factors),

$$244197000982499715087866346,$$

$$554079914617070801288578559178$$

(8 factors), ... (Sloane's A007850).

It is not known if there are an infinite number of Giuga numbers. All the above numbers have sum minus product equal to 1, and any Giuga number of higher order must have at least 59 factors. The smallest ODD Giuga number must have at least nine PRIME factors.

see also ARGOH'S CONJECTURE, BERNOULLI NUMBER, TOTIENT FUNCTION

#### References

Sloane, N. J. A. Sequence A007850 in "An On-Line Version of the Encyclopedia of Integer Sequences."

#### Giuga Sequence

A finite, increasing sequence of INTEGERS  $\{n_1, \dots, n_m\}$  such that

$$\sum_{i=1}^m \frac{1}{n_i} - \prod_{i=1}^m \frac{1}{n_i} \in \mathbb{N}.$$

A sequence is a Giuga sequence IFF it satisfies

$$n_i | (n_1 \cdots n_{i-1} \cdot n_{i+1} \cdots n_m - 1)$$

for  $i = 1, \dots, m$ . There are no Giuga sequences of length 2, one of length 3 ( $\{2, 3, 5\}$ ), two of length 4 ( $\{2, 3, 7, 41\}$  and  $\{2, 3, 11, 13\}$ ), 3 of length 5 ( $\{2, 3, 7, 43, 1805\}$ ,  $\{2, 3, 7, 83, 85\}$ , and  $\{2, 3, 11, 17, 59\}$ ), 17 of length 6, 27 of length 7, and hundreds of length 8. There are infinitely many Giuga sequences. It is possible to generate longer Giuga sequences from shorter ones satisfying certain properties.

see also CARMICHAEL SEQUENCE

#### References

#### Glaisher-Kinkelin Constant

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Define

$$K(n+1) \equiv 0^0 1^1 2^2 3^3 \cdots n^n \quad (1)$$

$$G(n+1) \equiv \frac{(n!)^n}{K(n+1)} = \begin{cases} 1 & \text{if } n = 0 \\ 0!1!2!\cdots(n-1)! & \text{if } n > 0. \end{cases} \quad (2)$$

where  $G$  is the  $G$ -FUNCTION and  $K$  is the  $K$ -FUNCTION. Then

$$\lim_{n \rightarrow \infty} \frac{K(n+1)}{n^{n^2/2+n/2+1/2} e^{-n^2/4}} = A \quad (3)$$

$$\lim_{n \rightarrow \infty} \frac{G(n+1)}{n^{n^2/2-1/12} (2\pi)^{n/2} e^{-3n^2/4}} = \frac{e^{1/12}}{A}, \quad (4)$$

where

$$A = \exp \left[ -\frac{\zeta'(2)}{2\pi^2} + \frac{\ln(2\pi)}{12} + \frac{\gamma}{2} \right] = 1.28242713 \dots, \quad (5)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION,  $\pi$  is PI, and  $\gamma$  is the EULER-MASCHERONI CONSTANT (Kinkelin 1860, Glaisher 1877, 1878, 1893, 1894). Glaisher (1877) also obtained

$$A = 2^{7/36} \pi^{-1/6} \exp \left\{ \frac{1}{3} + \frac{2}{3} \int_0^{1/2} \ln[\Gamma(x+1)] dx \right\}. \quad (6)$$

Glaisher (1894) showed that

$$1^{1/1} 2^{1/4} 3^{1/9} 4^{1/16} 5^{1/25} \dots = \left( \frac{A^{12}}{2\pi e^\gamma} \right)^{\pi^2/6} \quad (7)$$

$$1^{1/1} 3^{1/9} 5^{1/25} 7^{1/49} 9^{1/81} \dots = \left( \frac{A^{12}}{2^{4/3} \pi e^\gamma} \right)^{\pi^2/8} \quad (8)$$

$$\frac{1^{1/1} 5^{1/125} 9^{1/729} \dots}{3^{1/27} 7^{1/343} 11^{1/1331} \dots} = \left( \frac{A}{2^{5/32} \pi^{1/32} e^{3/32 + \gamma/48 + s/4}} \right)^{\pi^3}, \quad (9)$$

where

$$s \equiv \frac{\zeta(3)}{3 \cdot 4 \cdot 5 \cdot 4^3} + \frac{\zeta(5)}{5 \cdot 6 \cdot 7 \cdot 4^5} + \frac{\zeta(7)}{7 \cdot 8 \cdot 9 \cdot 4^7} + \dots \quad (10)$$

see also  $G$ -FUNCTION, HYPERFACTORIAL,  $K$ -FUNCTION

**Glide**

A product of a REFLECTION in a line and TRANSLATION along the same line.

see also REFLECTION, TRANSLATION

**Glissette**

The locus of a point  $P$  (or the envelope of a line) fixed in relation to a curve  $C$  which slides between fixed curves. For example, if  $C$  is a line segment and  $P$  a point on the line segment, then  $P$  describes an ELLIPSE when  $C$  slides so as to touch two ORTHOGONAL straight LINES. The glissette of the LINE SEGMENT  $C$  itself is, in this case, an ASTROID.

see also ROULETTE

**Global  $C(G; T)$  Theorem**

If a SYLOW 2-SUBGROUP  $T$  of  $G$  lies in a unique maximal 2-local  $P$  of  $G$ , then  $P$  is a "strongly embedded" SUBGROUP of  $G$ , and  $G$  is known.

**Global Extremum**

A GLOBAL MINIMUM or GLOBAL MAXIMUM.

see also LOCAL EXTREMUM

**Global Maximum**

The largest overall value of a set, function, etc., over its entire range.

see also GLOBAL MINIMUM, LOCAL MAXIMUM, MAXIMUM

**Global Minimum**

The smallest overall value of a set, function, etc., over its entire range.

see also GLOBAL MAXIMUM, KUHN-TUCKER THEOREM, LOCAL MINIMUM, MINIMUM

**Globe**

A SPHERE which acts as a model of a spherical (or ellipsoidal) celestial body, especially the Earth, and on which the outlines of continents, oceans, etc. are drawn.

see also LATITUDE, LONGITUDE, SPHERE

**Glove Problem**

Let there be  $m$  doctors and  $n \leq m$  patients, and let all  $mn$  possible combinations of examinations of patients by doctors take place. Then what is the minimum number of surgical gloves needed  $G(m, n)$  so that no doctor must wear a glove contaminated by a patient and no patient is exposed to a glove worn by another doctor? In this problem, the gloves can be turned inside out and even placed on top of one another if necessary, but no "decontamination" of gloves is permitted. The optimal solution is

$$g(m, n) = \begin{cases} 2 & m = n = 2 \\ \frac{1}{2}(m+1) & n = 1, m = 2k+1 \\ \lceil \frac{1}{2}(m) + \frac{2}{3}n \rceil & \text{otherwise,} \end{cases}$$

where  $\lceil x \rceil$  is the CEILING FUNCTION (Vardi 1991). The case  $m = n = 2$  is straightforward since two gloves have a total of four surfaces, which is the number needed for  $mn = 4$  examinations.

**Glue Vector**

A VECTOR specifying how layers are stacked in a LAMINATED LATTICE.

**Gnomonic Number**

A FIGURATE NUMBER of the form  $g_n = 2n - 1$  which are the areas of square gnomons, obtained by removing a SQUARE of side  $n - 1$  from a SQUARE of side  $n$ ,

$$g_n = n^2 - (n - 1)^2 = 2n - 1.$$

The gnomonic numbers are therefore equivalent to the ODD NUMBERS, and the first few are 1, 3, 5, 7, 9, 11, ... (Sloane's A005408). The GENERATING FUNCTION for the gnomonic numbers is

$$\frac{x(1+x)}{(x-1)^2} = x + 3x^2 + 5x^3 + 7x^4 + \dots$$

see also ODD NUMBER

- Sloane, N. J. A. Sequence A005408/M2400 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Gnomonic Projection

A nonconformal projection from a SPHERE's center in which ORTHODROMES are straight LINES.

$$x = \frac{\cos \phi \sin(\lambda - \lambda_0)}{\cos c} \quad (1)$$

$$y = \frac{\cos \phi_1 \sin \phi - \sin \phi_1 \cos \phi \cos(\lambda - \lambda_0)}{\cos c}, \quad (2)$$

where

$$\cos c = \sin \phi_1 \sin \phi + \cos \phi_1 \cos \phi \cos(\lambda - \lambda_0). \quad (3)$$

The inverse FORMULAS are

$$\phi = \sin^{-1}(\cos c \sin \phi_1 + y \sin c \cos \phi_1) \quad (4)$$

$$\lambda = \lambda_0 + \tan^{-1} \left( \frac{x}{\cos \phi_1 - y \sin \phi_1} \right). \quad (5)$$

## Göbel's Sequence

Consider the RECURRENCE RELATION

$$x_n = \frac{1 + x_0^2 + x_1^2 + \dots + x_{n-1}^2}{n}, \quad (1)$$

with  $x_0 = 1$ . The first few iterates of  $x_n$  are 1, 2, 3, 5, 10, 28, 154, ... (Sloane's A003504). The terms grow extremely rapidly, but are given by the asymptotic formula

$$x_n \approx (n^2 + 2n - 1 + 4n^{-1} - 21n^{-2} + 137n^{-3} - \dots) C^{2^n}, \quad (2)$$

where

$$C = 1.04783144757641122955990946274313755459... \quad (3)$$

(Zagier). It is more convenient to work with the transformed sequence

$$s_n = 2 + x_1^2 + x_2^2 + \dots + x_{n-1}^2 = nx_n, \quad (4)$$

which gives the new recurrence

$$s_{n+1} = s_n + \frac{s_n^2}{n^2} \quad (5)$$

with initial condition  $s_1 = 2$ . Now,  $s_{n+1}$  will be nonintegral IFF  $n \nmid s_n$ . The smallest  $p$  for which  $s_p \not\equiv 0 \pmod{p}$  therefore gives the smallest nonintegral  $s_{p+1}$ . In addition, since  $p \mid s_p$ ,  $x_p = s_p/p$  is also the smallest nonintegral  $x_p$ .

For example, we have the sequences  $\{s_n \pmod{k}\}_{n=1}^k$ :

$$2, 6 \equiv 2, \frac{5}{4} \equiv 0, 0, 0 \pmod{5} \quad (6)$$

$$2, 6, 15 \equiv 1, \frac{5}{4} \equiv 0, 0, 0 \pmod{7} \quad (7)$$

$$2, 6, 15 \equiv 4, \frac{52}{9} \equiv 7, \frac{161}{16} \equiv 8, \frac{264}{5} \equiv 0, 0, \dots, 0 \pmod{11}. \quad (8)$$

Testing values of  $k$  shows that the first nonintegral  $x_n$  is  $x_{43}$ . Note that a direct verification of this fact is impossible since

$$x_{43} \approx 5.4093 \times 10^{17485291567} \quad (9)$$

(calculated using the asymptotic formula) is much too large to be computed and stored explicitly.

A sequence even more striking for remaining integral over many terms is the 3-Göbel sequence

$$x_n = \frac{1 + x_0^3 + x_1^3 + \dots + x_{n-1}^3}{n}. \quad (10)$$

The first few terms of this sequence are 1, 2, 5, 45, 22815, ... (Sloane's A005166).

The Göbel sequences can be generalized to  $k$  powers by

$$x_n = \frac{1 + x_0^k + x_1^k + \dots + x_{n-1}^k}{n}. \quad (11)$$

see also SOMOS SEQUENCE

#### Gödel's Completeness Theorem

If  $T$  is a set of AXIOMS in a first-order language, and a statement  $p$  holds for any structure  $M$  satisfying  $T$ , then  $p$  can be formally deduced from  $T$  in some appropriately defined fashion.

see also GÖDEL'S INCOMPLETENESS THEOREM

#### Gödel's Incompleteness Theorem

Informally, Gödel's incompleteness theorem states that all consistent axiomatic formulations of NUMBER THEORY include undecidable propositions (Hofstadter 1989). This is sometimes called Gödel's first incompleteness theorem, and answers in the negative HILBERT'S PROBLEM asking whether mathematics is "complete" (in the sense that every statement in the language of NUMBER THEORY can be either proved or disproved). Formally, Gödel's theorem states, "To every  $\omega$ -consistent recursive class  $\kappa$  of FORMULAS, there correspond recursive class-signs  $r$  such that neither  $(\forall \text{ Gen } r)$  nor  $\text{Neg}(\forall \text{ Gen } r)$  belongs to  $\text{Flg}(\kappa)$ , where  $v$  is the FREE VARIABLE of  $r$ " (Gödel 1931).

A statement sometimes known as Gödel's second incompleteness theorem states that if NUMBER THEORY is consistent, then a proof of this fact does not exist using the methods of first-order PREDICATE CALCULUS. Stated more colloquially, any formal system that is interesting enough to formulate its own consistency can prove its own consistency IFF it is inconsistent.

Gerhard Gentzen showed that the consistency and completeness of arithmetic can be proved if "transfinite" induction is used. However, this approach does not allow proof of the consistency of all mathematics.

#### Gödel Number

A Gödel number is a unique number associated to a statement about arithmetic. It is formed as the PRODUCT of successive PRIMES raised to the POWER of the number corresponding to the individual symbols that comprise the sentence. For example, the statement  $(\exists x)(x = sy)$  that reads "there EXISTS an  $x$  such that  $x$  is the immediate successor of  $y$ " is coded

$$(2^8)(3^4)(5^{13})(7^9)(11^8)(13^{13})(17^5)(19^7)(23^{16})(29^9),$$

where the numbers in the set (8, 4, 13, 9, 8, 13, 5, 7, 16, 9) correspond to the symbols that make up  $(\exists x)(x = sy)$ .

### Goldbach Conjecture

Goldbach's original conjecture, written in a 1742 letter to Euler, states that every INTEGER  $> 5$  is the SUM of three PRIMES. As re-expressed by Euler, an equivalent of this CONJECTURE (called the "strong" Goldbach conjecture) asserts that all POSITIVE EVEN INTEGERS  $\geq 4$  can be expressed as the SUM of two PRIMES. Schnirelmann (1931) proved that every EVEN number can be written as the sum of not more than 300,000 PRIMES (Dunham 1990), which seems a rather far cry from a proof for *four* PRIMES! The strong Goldbach conjecture has been shown to be true up to  $4 \times 10^{11}$  by Sinisalo (1993). Pogorzelski (1977) claimed to have proven the Goldbach conjecture, but his proof is not generally accepted (Shanks 1993).

The conjecture that all ODD numbers  $\geq 9$  are the SUM of three ODD PRIMES is called the "weak" Goldbach conjecture. Vinogradov proved that all ODD INTEGERS starting at some sufficiently large value are the SUM of three PRIMES (Guy 1994). The original "sufficiently large"  $N \geq 3^{3^{15}} = e^{16.573}$  was subsequently reduced to  $e^{11.503}$  by Chen and Wang (1989). Chen (1973, 1978) also showed that all sufficiently large EVEN NUMBERS are the sum of a PRIME and the PRODUCT of at most two PRIMES (Guy 1994, Courant and Robbins 1996).

It has been shown that if the weak Goldbach conjecture is false, then there are only a FINITE number of exceptions.

Other variants of the Goldbach conjecture include the statements that every EVEN number  $\geq 6$  is the SUM of two ODD PRIMES, and every INTEGER  $> 17$  the sum of exactly three distinct PRIMES. Let  $R(n)$  be the number of representations of an EVEN INTEGER  $n$  as the sum of two PRIMES. Then the "extended" Goldbach conjecture states that

$$R(n) \sim 2\Pi_2 \prod_{\substack{k=2 \\ p_k | n}} \frac{p_k - 1}{p_k - 2} \int_2^x \frac{dx}{(\ln x)^2},$$

where  $\Pi_2$  is the TWIN PRIMES CONSTANT (Halberstam and Richert 1974).

If the Goldbach conjecture is true, then for every number  $m$ , there are PRIMES  $p$  and  $q$  such that

$$\phi(p) + \phi(q) = 2m,$$

where  $\phi(x)$  is the TOTIENT FUNCTION (Guy 1994, p. 105).

Vinogradov (1937ab, 1954) proved that every sufficiently large ODD NUMBER is the sum of three PRIMES, and Estermann (1938) proves that almost all EVEN NUMBERS are the sums of two PRIMES.

### Golden Mean

see GOLDEN RATIO

### Golden Ratio

A number often encountered when taking the ratios of distances in simple geometric figures such as the DECAGON and DODECAGON. It is denoted  $\phi$ , or sometimes  $\tau$  (which is an abbreviation of the Greek "tome," meaning "to cut").  $\phi$  is also known as the DIVINE PROPORTION, GOLDEN MEAN, and GOLDEN SECTION and is a PISOT-VIJAYARAGHAVAN CONSTANT. It has surprising connections with CONTINUED FRACTIONS and the

EUCLIDEAN ALGORITHM for computing the GREATEST COMMON DIVISOR of two INTEGERS.

Given a RECTANGLE having sides in the ratio  $1 : \phi$ ,  $\phi$  is defined such that partitioning the original RECTANGLE into a SQUARE and new RECTANGLE results in a new RECTANGLE having sides with a ratio  $1 : \phi$ . Such a RECTANGLE is called a GOLDEN RECTANGLE, and successive points dividing a GOLDEN RECTANGLE into SQUARES lie on a LOGARITHMIC SPIRAL. This figure is known as a WHIRLING SQUARE.

This means that

$$\frac{1}{\phi - 1} = \phi \quad (1)$$

$$\phi^2 - \phi - 1 = 0. \quad (2)$$

So, by the QUADRATIC EQUATION,

$$\phi = \frac{1}{2}(1 \pm \sqrt{1+4}) = \frac{1}{2}(1 + \sqrt{5}) \quad (3)$$

$$= 1.618033988749894848204586834365638117720... \quad (4)$$

(Sloane's A001622).

A geometric definition can be given in terms of the above figure. Let the ratio  $x \equiv AB/BC$ . The NUMERATOR and DENOMINATOR can then be taken as  $AB = x$  and  $BC = 1$  without loss of generality. Now define the position of  $B$  by

$$\frac{BC}{AB} = \frac{AB}{AC}. \quad (5)$$

Plugging in gives

$$\frac{1}{x} = \frac{x}{1+x}, \quad (6)$$

or

$$x^2 - x - 1 = 0, \quad (7)$$

which can be solved using the QUADRATIC EQUATION to obtain

$$\phi \equiv x = \frac{1 \pm \sqrt{1^2 - (-4)}}{2} = \frac{1}{2}(1 + \sqrt{5}). \quad (8)$$

$\phi$  is the "most" IRRATIONAL number because it has a CONTINUED FRACTION representation

$$\phi = [1, 1, 1, 1, \dots] \quad (9)$$

(Sloane's A000012). Another infinite representation in terms of a CONTINUED SQUARE ROOT is

$$\phi = \sqrt{1 + \sqrt{1 + \sqrt{1 + \sqrt{1 + \dots}}}} \quad (10)$$

Ramanujan gave the curious CONTINUED FRACTION identities

$$\frac{1}{(\sqrt{\phi\sqrt{5}})e^{2\pi/5}} = 1 + \frac{e^{-2\pi}}{1 + \frac{e^{-4\pi}}{1 + \frac{e^{-6\pi}}{1 + \frac{e^{-8\pi}}{1 + \frac{e^{-10\pi}}{1 + \dots}}}}} \quad (11)$$

$$\frac{1}{\left\{ \frac{\sqrt{5}}{1 + [5^{3/4}(\phi-1)^{5/2} - 1] - \phi} \right\} e^{2\pi/\sqrt{5}}} = 1 + \frac{e^{-2\pi\sqrt{5}}}{1 + \frac{e^{-4\pi\sqrt{5}}}{1 + \frac{e^{-6\pi\sqrt{5}}}{1 + \frac{e^{-8\pi\sqrt{5}}}{1 + \frac{e^{-10\pi\sqrt{5}}}{1 + \dots}}}}} \quad (12)$$

(Ramanathan 1984).

The legs of a GOLDEN TRIANGLE are in a golden ratio to its base. In fact, this was the method used by Pythagoras to construct  $\phi$ . Euclid used the following construction.

Draw the SQUARE  $\square ABDC$ , call  $E$  the MIDPOINT of  $AC$ , so that  $AE = EC \equiv x$ . Now draw the segment  $BE$ , which has length

$$x\sqrt{2^2 + 1^2} = x\sqrt{5}, \quad (13)$$

and construct  $EF$  with this length. Now construct  $FG = EF$ , then

$$\phi = \frac{FC}{CD} = \frac{EF + CE}{CD} = \frac{x(\sqrt{5} + 1)}{2x} = \frac{1}{2}(\sqrt{5} + 1). \quad (14)$$

The ratio of the CIRCUMRADIUS to the length of the side of a DECAGON is also  $\phi$ ,

$$\frac{R}{s} = \frac{1}{2} \csc\left(\frac{\pi}{10}\right) = \frac{1}{2}(1 + \sqrt{5}) = \phi. \quad (15)$$

Similarly, the legs of a GOLDEN TRIANGLE (an ISOSCELES TRIANGLE with a VERTEX ANGLE of  $36^\circ$ ) are in a GOLDEN RATIO to the base. Bisecting a GAULLIST CROSS also gives a golden ratio (Gardner 1961, p. 102).

In the figure above, three TRIANGLES can be INSCRIBED in the RECTANGLE  $\square ABCD$  of arbitrary aspect ratio  $1 : r$  such that the three RIGHT TRIANGLES have equal areas by dividing  $AB$  and  $BC$  in the golden ratio. Then

$$K_{\triangle ADE} = \frac{1}{2} \cdot r(1 + \phi) \cdot 1 = \frac{1}{2} r \phi^2 \quad (16)$$

$$K_{\triangle BEF} = \frac{1}{2} \cdot r \phi \cdot \phi = \frac{1}{2} r \phi^2 \quad (17)$$

$$K_{\triangle CDF} = \frac{1}{2} (1 + \phi) \cdot r = \frac{1}{2} r \phi^2, \quad (18)$$

which are all equal.

The golden ratio also satisfies the RECURRENCE RELATION

$$\phi^{n+1} = \phi^{n-1} + \phi^n. \quad (19)$$

Taking  $n = 0$  gives

$$\phi = \phi^{-1} + 1 \quad (20)$$

$$\phi^2 = 1 + \phi. \quad (21)$$

But this is the definition equation for  $\phi$  (when the root with the plus sign is used). Squaring gives

$$\begin{aligned} \phi^2 &= \frac{1}{4}(5 + 2\sqrt{5} + 1) = \frac{1}{4}(6 + 2\sqrt{5}) = \frac{1}{2}(3 + \sqrt{5}) \\ &= \frac{1}{2}(\sqrt{5} + 1) + 1 = \phi^0 + \phi^1 \end{aligned} \quad (22)$$

$$\phi^3 = (\phi^0 + \phi^1)\phi^1 = \phi^0\phi^1 + (\phi^1)^2 = \phi^1 + \phi^2, \quad (23)$$

and so on.

For the difference equations

$$\begin{cases} x_0 = 1 \\ x_n = 1 + \frac{1}{x_{n-1}} \end{cases} \text{ for } n = 1, 2, 3, \quad (24)$$

$\phi$  is also given by

$$\phi = \lim_{n \rightarrow \infty} x_n. \quad (25)$$

In addition,

$$\phi = \lim_{n \rightarrow \infty} \frac{F_n}{F_{n-1}}, \quad (26)$$

where  $F_n$  is the  $n$ th FIBONACCI NUMBER.

The SUBSTITUTION MAP

$$0 \rightarrow 01 \quad (27)$$

$$1 \rightarrow 0 \quad (28)$$

gives

$$0 \rightarrow 01 \rightarrow 010 \rightarrow 01001 \rightarrow \dots, \quad (29)$$

giving rise to the sequence

$$0100101001001010010100100101\dots \quad (30)$$

(Sloane's A003849). Here, the zeros occur at positions 1, 3, 4, 6, 8, 9, 11, 12, ... (Sloane's A000201), and the ones occur at positions 2, 5, 7, 10, 13, 15, 18, ... (Sloane's A001950). These are complementary BEATTY SEQUENCES generated by  $\lfloor n\phi \rfloor$  and  $\lfloor n\phi^2 \rfloor$ . The sequence also has many connections with the FIBONACCI NUMBERS.

Salem showed that the set of PISOT-VIJAYARAGHAVAN CONSTANTS is closed, with  $\phi$  the smallest accumulation point of the set (Le Lionnais 1983).

### Golden Ratio Conjugate

The quantity

$$\phi_C \equiv \frac{1}{\phi} = \phi - 1 = \frac{\sqrt{5} - 1}{2} \approx 0.6180339885, \quad (1)$$

where  $\phi$  is the GOLDEN RATIO. The golden ratio conjugate is sometimes also called the SILVER RATIO. A quantity similar to the FEIGENBAUM CONSTANT can be found for the  $n$ th CONTINUED FRACTION representation

$$[a_0, a_1, a_2, \dots]. \quad (2)$$

Taking the limit of

$$\delta_n \equiv \frac{\sigma_n - \sigma_{n-1}}{\sigma_n - \sigma_{n+1}} \quad (3)$$

gives

$$\delta \equiv \lim_{n \rightarrow \infty} = 1 + \phi = 2 + \phi_C. \quad (4)$$

see also GOLDEN RATIO, SILVER RATIO

### Golden Rectangle

Given a RECTANGLE having sides in the ratio  $1 : \phi$ , the GOLDEN RATIO  $\phi$  is defined such that partitioning the original RECTANGLE into a SQUARE and new RECTANGLE results in a new RECTANGLE having sides with a ratio  $1 : \phi$ . Such a RECTANGLE is called a golden rectangle, and successive points dividing a golden rectangle into SQUARES lie on a LOGARITHMIC SPIRAL.

### Golden Section

see GOLDEN RATIO

### Golden Theorem

see QUADRATIC RECIPROCITY THEOREM

### Golden Triangle

An ISOSCELES TRIANGLE with VERTEX angles  $36^\circ$ . Such TRIANGLES occur in the PENTAGRAM and DECAGON. The legs are in a GOLDEN RATIO to the base. For such a TRIANGLE,

$$\sin(18^\circ) = \sin\left(\frac{1}{10}\pi\right) = \frac{\frac{1}{2}b}{l} \quad (1)$$

$$b = 2a \sin\left(\frac{1}{10}\pi\right) = 2a \frac{\sqrt{5} - 1}{4} = \frac{1}{2}a(\sqrt{5} - 1) \quad (2)$$

$$b + l = \frac{1}{2}a(\sqrt{5} + 1) \quad (3)$$

$$\frac{b + a}{a} = \frac{\sqrt{5} + 1}{2} = \phi. \quad (4)$$

### Goldschmidt Solution

The discontinuous solution of the SURFACE OF REVOLUTION AREA minimization problem for surfaces connecting two CIRCLES. When the CIRCLES are sufficiently far apart, the usual CATENOID is no longer stable and the surface will break and form two surfaces with the CIRCLES as boundaries.

see also CALCULUS OF VARIATIONS, SURFACE OF REVOLUTION

### Golomb Constant

see GOLOMB-DICKMAN CONSTANT

**Golomb-Dickman Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let  $\Pi$  be a PERMUTATION of  $n$  elements, and let  $\alpha_i$  be the number of CYCLES of length  $i$  in this PERMUTATION. Picking  $\Pi$  at RANDOM gives

$$\left\langle \sum_{j=1}^{\infty} \alpha_j \right\rangle = \sum_{i=1}^n \frac{1}{i} = \ln n + \gamma + \mathcal{O}\left(\frac{1}{n}\right) \quad (1)$$

$$\text{var} \left( \sum_{j=1}^{\infty} \alpha_j \right) = \sum_{i=1}^n \frac{i-1}{i^2} = \ln n + \gamma - \frac{1}{6}\pi^2 + \mathcal{O}\left(\frac{1}{n}\right) \quad (2)$$

$$\lim_{n \rightarrow \infty} P(\alpha_1 = 0) = \frac{1}{e} \quad (3)$$

(Shepp and Lloyd 1966, Wilf 1990). Goncharov (1942) showed that

$$\lim_{n \rightarrow \infty} P(\alpha_j = k) = \frac{1}{k!} e^{-1/j} j^{-k}, \quad (4)$$

which is a POISSON DISTRIBUTION, and

$$\lim_{n \rightarrow \infty} P \left[ \left( \sum_{j=1}^{\infty} \alpha_j - \ln n \right) (\ln n)^{-1/2} \leq x \right] = \Phi(x), \quad (5)$$

which is a NORMAL DISTRIBUTION,  $\gamma$  is the EULER-MASCHERONI CONSTANT, and  $\Phi$  is the NORMAL DISTRIBUTION FUNCTION. Let

$$M(\alpha) \equiv \max_{1 \leq j < \infty} \alpha_j \quad (6)$$

$$m(\alpha) \equiv \min_{1 \leq j < \infty} \alpha_j. \quad (7)$$

Golomb (1959) derived

$$\lambda \equiv \lim_{n \rightarrow \infty} \frac{\langle M(\alpha) \rangle}{n} = 0.6243299885 \dots, \quad (8)$$

which is known as the GOLOMB CONSTANT or Golomb-Dickman constant. Knuth (1981) asked for the constants  $b$  and  $c$  such that

$$\lim_{n \rightarrow \infty} n^b [\langle M(\alpha) \rangle - \lambda n - \frac{1}{2} \lambda] = c, \quad (9)$$

and Gourdon (1996) showed that

$$\langle M(\alpha) \rangle = \lambda \left( n + \frac{1}{2} \right) - \frac{e^\gamma}{24n} + \frac{\frac{1}{48}e^\gamma - \frac{1}{8}(-1)^n}{n^2} + \frac{\frac{17}{3840}e^\gamma + \frac{1}{8}(-1)^n + \frac{1}{6}j^{1+2n} + \frac{1}{6}j^{2+n}}{n^3}, \quad (10)$$

where

$$j \equiv e^{2\pi i/3}. \quad (11)$$

$\lambda$  can be expressed in terms of the function  $f(x)$  defined by  $f(x) = 1$  for  $1 \leq x \leq 2$  and

$$\frac{df}{dx} = -\frac{f(x-1)}{x-1} \quad (12)$$

for  $x > 2$ , by

$$\lambda = \int_1^\infty \frac{f(x)}{x^2} dx. \quad (13)$$

Shepp and Lloyd (1966) derived

$$\begin{aligned} \lambda &= \int_0^\infty \exp \left( -x - \int_x^\infty \frac{e^{-y}}{y} dy \right) \\ &= \int_0^1 \exp \left( \int_0^x \frac{dy}{\ln y} \right) dx. \end{aligned} \quad (14)$$

Mitchell (1968) computed  $\lambda$  to 53 decimal places.

Surprisingly enough, there is a connection between  $\lambda$  and PRIME FACTORIZATION (Knuth and Pardo 1976, Knuth 1981, pp. 367–368, 395, and 611). Dickman (1930) investigated the probability  $P(x, n)$  that the largest PRIME FACTOR  $p$  of a random INTEGER between 1 and  $n$  satisfies  $p < n^x$  for  $x \in (0, 1)$ . He found that

$$F(x) \equiv \lim_{n \rightarrow \infty} P(x, n) = \begin{cases} 1 & \text{if } x \geq 1 \\ \int_0^x F\left(\frac{t}{1-t}\right) \frac{dt}{t} & \text{if } 0 \leq x < 1. \end{cases} \quad (15)$$

Dickman then found the average value of  $x$  such that  $p = n^x$ , obtaining

$$\begin{aligned} \mu &\equiv \lim_{n \rightarrow \infty} \langle x \rangle = \lim_{n \rightarrow \infty} \left\langle \frac{\ln p}{\ln n} \right\rangle = \int_0^1 x \frac{dF}{dx} dx \\ &= \int_0^1 F\left(\frac{1}{1-t}\right) dt = 0.62432999, \end{aligned} \quad (16)$$

which is  $\lambda$ .

### Golomb Ruler

A Golomb ruler is a set of NONNEGATIVE integers such that all pairwise POSITIVE differences are distinct. The optimum Golomb ruler with  $n$  marks is the Golomb ruler having the smallest possible maximum element ("length"). The set  $(0, 1, 3, 7)$  is an order four Golomb ruler since its differences are  $(1 = 1 - 0, 2 = 3 - 1, 3 = 3 - 0, 4 = 7 - 3, 6 = 7 - 1, 7 = 7 - 0)$ , all of which are distinct. However, the optimum 4-mark Golomb ruler is  $(0, 1, 4, 6)$ , which measures the distances  $(1, 2, 3, 4, 5, 6)$  (and is therefore also a PERFECT RULER).

The lengths of the optimal  $n$ -mark Golomb rulers for  $n = 2, 3, 4, \dots$  are  $1, 3, 6, 11, 17, 25, 34, \dots$  (Sloane's A003022, Vanderschel and Garry). The lengths of the optimal  $n$ -mark Golomb rulers are not known for  $n \geq 20$ .

### Golygon

A PLANE path on a set of equally spaced LATTICE POINTS, starting at the ORIGIN, where the first step is one unit to the north or south, the second step is two units to the east or west, the third is three units to the north or south, etc., and continuing until the ORIGIN is again reached. No crossing or backtracking is allowed. The simplest golygon is  $(0, 0)$ ,  $(0, 1)$ ,  $(2, 1)$ ,  $(2, -2)$ ,  $(-2, -2)$ ,  $(-2, -7)$ ,  $(-8, -7)$ ,  $(-8, 0)$ ,  $(0, 0)$ .

A golygon can be formed if there exists an EVEN INTEGER  $n$  such that

$$\pm 1 \pm 3 \pm \dots \pm (n-1) = 0 \quad (1)$$

$$\pm 2 \pm 4 \pm \dots \pm n = 0 \quad (2)$$

(Vardi 1991). Gardner proved that all golygons are of the form  $n = 8k$ . The number of golygons of length  $n$  (EVEN), with each initial direction counted separately, is the PRODUCT of the COEFFICIENT of  $x^{n^2/8}$  in

$$(1+x)(1+x^3)\dots(1+x^{n-1}), \quad (3)$$

with the COEFFICIENT of  $x^{n(n/2+1)/8}$  in

$$(1+x)(1+x^2)\dots(1+x^{n/2}). \quad (4)$$

The number of golygons  $N(n)$  of length  $8n$  for the first few  $n$  are 4, 112, 8432, 909288, ... (Sloane's A006718) and is asymptotic to

$$N(n) \sim \frac{3 \cdot 2^{8n-4}}{\pi n^2(4n+1)} \quad (5)$$

(Sallows et al. 1991, Vardi 1991).

### Gomory's Theorem

Regardless of where one white and one black square are deleted from an ordinary  $8 \times 8$  CHESSBOARD, the reduced board can always be covered exactly with 31 DOMINOES (of dimension  $2 \times 1$ ).

see also CHESSBOARD

### Gompertz Constant

$$G \equiv \int_0^\infty \frac{e^{-u}}{1+u} du = -e \operatorname{ei}(-1) = 0.596347362\dots,$$

where  $\operatorname{ei}(x)$  is the EXPONENTIAL INTEGRAL. Stieltjes showed it has the CONTINUED FRACTION representation

$$G = \frac{1}{2 - \frac{1^2}{4 - \frac{2^2}{6 - \frac{3^2}{8 - \dots}}}}$$

see also EXPONENTIAL INTEGRAL

**Gompertz Curve**

The function defined by

$$y = ab^{a^x}.$$

It is used in actuarial science for specifying a simplified mortality law. Using  $s(x)$  as the probability that a newborn will achieve age  $x$ , the Gompertz law (1825) is

$$s(x) = \exp[-m(c^x - 1)],$$

for  $c > 1$ ,  $x \geq 0$ .

see POLYGONAL NUMBER

**Good Path**

see  $p$ -GOOD PATH

**Good Prime**

A PRIME  $p_n$  is called "good" if

$$p_n^2 > p_{n-i}p_{n+i}$$

for all  $1 \leq i \leq n-1$  (there is a typo in Guy 1994 in which the  $is$  are replaced by  $1s$ ). There are infinitely many good primes, and the first few are 5, 11, 17, 29, 37, 41, 53, ... (Sloane's A028388).

**Goodman's Formula**

A two-coloring of a COMPLETE GRAPH  $K_n$  of  $n$  nodes which contains exactly the number of MONOCHROMATIC FORCED TRIANGLES and no more (i.e., a minimum of  $R+B$  where  $R$  and  $B$  are the number of red and blue TRIANGLES) is called an EXTREMAL GRAPH. Goodman (1959) showed that for an extremal graph,

$$R+B = \begin{cases} \frac{1}{6}m(m-1)(m-2) & \text{for } n = 2m \\ \frac{1}{6}m(m-1)(4m+1) & \text{for } n = 4m+1 \\ \frac{1}{6}m(m+1)(4m-1) & \text{for } n = 4m+3. \end{cases}$$

Schwenk (1972) rewrote the equation in the form

$$R+B = \binom{n}{3} - \left\lfloor \frac{1}{2}n \left\lfloor \frac{1}{4}(n-1)^2 \right\rfloor \right\rfloor,$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT and  $\lfloor x \rfloor$  is the FLOOR FUNCTION.

**Goodstein Sequence**

Given a HEREDITARY REPRESENTATION of a number  $n$  in BASE, let  $B[b](n)$  be the NONNEGATIVE INTEGER which results if we syntactically replace each  $b$  by  $b+1$  (i.e.,  $B[b]$  is a base change operator that 'bumps the base' from  $b$  up to  $b+1$ ). The HEREDITARY REPRESENTATION of 266 in base 2 is

$$\begin{aligned} 266 &= 2^8 + 2^3 + 2 \\ &= 2^{2^{2+1}} + 2^{2+1} + 2, \end{aligned}$$

so bumping the base from 2 to 3 yields

$$B[2](266) = 3^{3^{3+1}} + 3^{3+1} + 3.$$

Now repeatedly bump the base and subtract 1,

$$\begin{aligned} G_0(266) &= 266 = 2^{2^{2+1}} + 2^{2+1} + 2 \\ G_1(266) &= B[2](266) - 1 = 3^{3^{3+1}} + 3^{3+1} + 2 \\ G_2(266) &= B[3](G_1) - 1 = 4^{4^{4+1}} + 4^{4+1} + 1 \\ G_3(266) &= B[4](G_2) - 1 = 5^{5^{5+1}} + 5^{5+1} \\ G_4(266) &= B[5](G_3) - 1 = 6^{6^{6+1}} + 6^{6+1} - 1 \\ &= 6^{6^{6+1}} + 5 \cdot 6^6 + 5 \cdot 6^5 + \dots + 5 \cdot 6 + 5 \\ G_5(266) &= B[6](G_4) - 1 \\ &= 7^{7^{7+1}} + 5 \cdot 7^7 + 5 \cdot 7^5 + \dots + 5 \cdot 7 + 4, \end{aligned}$$

etc. Starting this procedure at an INTEGER  $n$  gives the Goodstein sequence  $\{G_k(n)\}$ . Amazingly, despite the apparent rapid increase in the terms of the sequence, GOODSTEIN'S THEOREM states that  $G_k(n)$  is 0 for any  $n$  and any sufficiently large  $k$ .

## Gosper Island

A modification of the KOCH SNOWFLAKE which has FRACTAL DIMENSION

$$D = \frac{2 \ln 3}{\ln 7} = 1.12915 \dots$$

The term "Gosper island" was used by Mandelbrot (1977) because this curve bounds the space filled by the PEANO-GOSPER CURVE; Gosper and Gardner use the term FLOWSNAKE FRACTAL instead. Gosper islands can TILE the PLANE.

see GOSPER'S ALGORITHM

## Graceful Graph

A LABELLED GRAPH which can be "gracefully numbered" is called a graceful graph. Label the nodes with distinct NONNEGATIVE INTEGERS. Then label the EDGES with the absolute differences between node values. If the EDGE numbers then run from 1 to  $e$ , the graph is gracefully numbered. In order for a graph to be graceful, it must be without loops or multiple EDGES.

Golomb showed that the number of EDGES connecting the EVEN-numbered and ODD-numbered sets of nodes is  $\lfloor (e+1)/2 \rfloor$ , where  $e$  is the number of EDGES. In addition, if the nodes of a graph are all of EVEN ORDER, then the graph is graceful only if  $\lfloor (e+1)/2 \rfloor$  is EVEN. The only ungraceful simple graphs with  $\leq 5$  nodes are shown below.

There are exactly  $e!$  graceful graphs with  $e$  EDGES (Sheppard 1976), where  $e!/2$  of these correspond to different labelings of the same graph. Golomb (1974) showed that all complete bipartite graphs are graceful. CATERPILLAR GRAPHS; COMPLETE GRAPHS  $K_2$ ,  $K_3$ ,  $K_4 = W_4 = T$  (and only these; Golomb 1974); CYCLIC GRAPHS  $C_n$  when  $n \equiv 0$  or  $3 \pmod{4}$ , when the number of consecutive chords  $k = 2, 3$ , or  $n - 3$  (Koh and Punim 1982), or when they contain a  $P_k$  chord (Delorme *et al.* 1980, Koh and Yap 1985, Punim and Pabhapote 1987); GEAR GRAPHS; PATH GRAPHS; the PETERSEN GRAPH; POLYHEDRAL GRAPHS  $T = K_4 = W_4$ ,  $C$ ,  $O$ ,  $D$ , and  $I$  (Gardner 1983); STAR GRAPHS; the THOMSEN GRAPH (Gardner 1983); and WHEEL GRAPHS (Frucht 1988) are all graceful.

Some graceful graphs have only one numbering, but others have more than one. It is conjectured that all trees are graceful (Bondy and Murty 1976), but this has only

been proved for trees with  $\leq 16$  VERTICES. It has also been conjectured that all unicyclic graphs are graceful.

An excellent on-line resource is Brundage (<http://www.math.washington.edu/~brundage/oldgraceful/>).

### Graded Algebra

If  $A$  is a graded module and there EXISTS a degree-preserving linear map  $\phi : A \otimes A \rightarrow A$ , then  $(A, \phi)$  is called a graded algebra.

### References

- Jacobson, N. *Lie Algebras*. New York: Dover, p. 163, 1979.

### Gradian

A unit of angular measure in which the angle of an entire CIRCLE is 400 gradians. A RIGHT ANGLE is therefore 100 gradians.

see also DEGREE, RADIAN

### Gradient

The gradient is a VECTOR operator denoted  $\nabla$  and sometimes also called DEL or NABLA. It most often is applied to a real function of three variables  $f(u_1, u_2, u_3)$ , and may be denoted

$$\nabla f \equiv \text{grad}(f). \quad (1)$$

For general CURVILINEAR COORDINATES, the gradient is given by

$$\nabla \phi = \frac{1}{h_1} \frac{\partial \phi}{\partial u_1} \hat{\mathbf{u}}_1 + \frac{1}{h_2} \frac{\partial \phi}{\partial u_2} \hat{\mathbf{u}}_2 + \frac{1}{h_3} \frac{\partial \phi}{\partial u_3} \hat{\mathbf{u}}_3, \quad (2)$$

which simplifies to

$$\nabla \phi(x, y, z) = \frac{\partial \phi}{\partial x} \hat{\mathbf{x}} + \frac{\partial \phi}{\partial y} \hat{\mathbf{y}} + \frac{\partial \phi}{\partial z} \hat{\mathbf{z}} \quad (3)$$

in CARTESIAN COORDINATES.

The direction of  $\nabla f$  is the orientation in which the DIRECTIONAL DERIVATIVE has the largest value and  $|\nabla f|$  is the value of that DIRECTIONAL DERIVATIVE. Furthermore, if  $\nabla f \neq 0$ , then the gradient is PERPENDICULAR to the LEVEL CURVE through  $(x_0, y_0)$  if  $z = f(x, y)$  and PERPENDICULAR to the level surface through  $(x_0, y_0, z_0)$  if  $F(x, y, z) = 0$ .

In TENSOR notation, let

$$ds^2 = g_\mu dx_\mu^2 \quad (4)$$

be the LINE ELEMENT in principal form. Then

$$\nabla_{\tilde{\epsilon}_\alpha} \tilde{\epsilon}_\beta = \nabla_\alpha \tilde{\epsilon}_\beta = \frac{1}{\sqrt{g_\alpha}} \frac{\partial}{\partial x_\alpha} \tilde{\epsilon}_\beta. \quad (5)$$

For a MATRIX  $A$ ,

$$\nabla |A\mathbf{x}| = \frac{(A\mathbf{x})^T A}{|A\mathbf{x}|}. \quad (6)$$

For expressions giving the gradient in particular coordinate systems, see CURVILINEAR COORDINATES.

#### Gradient Four-Vector

The 4-dimensional version of the GRADIENT, encountered frequently in general relativity and special relativity, is

$$\nabla_\mu = \left[ \begin{array}{c} \frac{1}{c} \frac{\partial}{\partial t} \\ \frac{\partial}{\partial x} \\ \frac{\partial}{\partial y} \\ \frac{\partial}{\partial z} \end{array} \right],$$

which can be written

$$(\nabla^\mu)^2 \equiv \square^2,$$

where  $\square^2$  is the D'ALEMBERTIAN OPERATOR.

see also D'ALEMBERTIAN OPERATOR, GRADIENT, TENSOR, VECTOR

#### References

Morse, P. M. and Feshbach, H. "The Differential Operator  $\nabla$ ." §1.4 in *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 31-44, 1953.

#### Gradient Theorem

$$\int_b^a (\nabla f) \cdot ds = f(b) - f(a),$$

where  $\nabla$  is the GRADIENT, and the integral is a LINE INTEGRAL. It is this relationship which makes the definition of a scalar potential function  $f$  so useful in gravitation and electromagnetism as a concise way to encode information about a VECTOR FIELD.

see also DIVERGENCE THEOREM, GREEN'S THEOREM, LINE INTEGRAL

#### Graeco-Latin Square

see EULER SQUARE

#### Graeco-Roman Square

see EULER SQUARE

#### Graeffe's Method

A ROOT-finding method which proceeds by multiplying a POLYNOMIAL  $f(x)$  by  $f(-x)$  and noting that

$$f(x) = (x - a_1)(x - a_2) \cdots (x - a_n) \quad (1)$$

$$f(-x) = (-1)^n (x + a_1)(x + a_2) \cdots (x + a_n) \quad (2)$$

so the result is

$$f(x)f(-x) = (-1)^n (x^2 - a_1^2)(x^2 - a_2^2) \cdots (x^2 - a_n^2). \quad (3)$$

Repeat  $\nu$  times, then write this in the form

$$y^n + b_1 y^{n-1} + \cdots + b_n = 0 \quad (4)$$

where  $y \equiv x^{2\nu}$ . Since the coefficients are given by NEWTON'S RELATIONS

$$b_1 = -(y_1 + y_2 + \cdots + y_n) \quad (5)$$

$$b_2 = (y_1 y_2 + y_1 y_3 + \cdots + y_{n-1} y_n) \quad (6)$$

$$b_n = (-1)^n y_1 y_2 \cdots y_n, \quad (7)$$

and since the squaring procedure has separated the roots, the first term is larger than rest. Therefore,

$$b_1 \approx -y_1 \quad (8)$$

$$b_2 \approx y_1 y_2 \quad (9)$$

$$b_n \approx (-1)^n y_1 y_2 \cdots y_n, \quad (10)$$

giving

$$y_1 \approx -b_1 \quad (11)$$

$$y_2 \approx -\frac{b_2}{b_1} \quad (12)$$

$$y_n \approx -\frac{b_n}{b_{n-1}}. \quad (13)$$

Solving for the original roots gives

$$a_1 \approx \sqrt[2\nu]{-b_1} \quad (14)$$

$$a_2 \approx \sqrt[2\nu]{-\frac{b_2}{b_1}} \quad (15)$$

$$a_n \approx \sqrt[2\nu]{-\frac{b_n}{b_{n-1}}}. \quad (16)$$

This method works especially well if all roots are real.

### Graham's Biggest Little Hexagon

The largest possible (not necessarily regular) HEXAGON for which no two of the corners are more than unit distance apart. In the above figure, the heavy lines are all of unit length. The AREA of the hexagon is  $A = 0.674981\dots$ , where  $A$  is a ROOT of

$$4096A^{10} - 8192A^9 - 3008A^8 - 30,848A^7 + 21,056A^6 + 146,496A^5 - 221,360A^4 + 1232A^3 + 144,464A^2 - 78,488A + 11,993 = 0.$$

### Graham's Number

The smallest dimension of a HYPERCUBE such that if the lines joining all pairs of corners are two-colored, a PLANAR COMPLETE GRAPH  $K_4$  of one color will be forced. That an answer exists was proved by R. L. Graham and B. L. Rothschild. The actual answer is believed to be 6, but the best bound proved is

$$64 \left\{ \begin{array}{l} 3 \uparrow \uparrow \uparrow \uparrow 3 \\ \underbrace{3 \uparrow 3} \\ \vdots \\ \underbrace{3 \uparrow 3} \end{array} \right.$$

where  $\uparrow$  is stacked ARROW NOTATION. It is less than  $3 \rightarrow 3 \rightarrow 3 \rightarrow 3$ , where CHAINED ARROW NOTATION has been used.

**Gram Matrix**

Given  $m$  points with  $n$ -D vector coordinates  $\mathbf{v}_i$ , let  $\mathbf{M}$  be the  $n \times m$  matrix whose  $j$ th column consists of the coordinates of the vector  $\mathbf{v}_j$ , with  $j = 1, \dots, m$ . Then define the  $m \times m$  Gram matrix of dot products  $a_{ij} = \mathbf{v}_i \cdot \mathbf{v}_j$  as

$$\mathbf{A} = \mathbf{M}^T \mathbf{M},$$

where  $\mathbf{A}^T$  denotes the TRANSPOSE. The Gram matrix determines the vectors  $\mathbf{v}_i$  up to ISOMETRY.

**Gram-Schmidt Orthonormalization**

A procedure which takes a nonorthogonal set of LINEARLY INDEPENDENT functions and constructs an ORTHOGONAL BASIS over an arbitrary interval with respect to an arbitrary WEIGHTING FUNCTION  $w(x)$ . Given an original set of linearly independent functions  $\{u_n\}$ , let  $\{\psi_n\}$  denote the orthogonalized (but not normalized) functions and  $\{\phi_n\}$  the orthonormalized functions.

$$\psi_0(x) \equiv u_1(x) \quad (1)$$

$$\phi_0(x) \equiv \frac{\psi_0(x)}{\sqrt{\int \psi_0^2(x) w(x) dx}}. \quad (2)$$

Take

$$\psi_1(x) = u_1(x) + a_{10}\phi_0(x), \quad (3)$$

where we require

$$\int \psi_1 \phi_0 w dx = \int u_1 \phi_0 w dx + a_{10} \int \phi_0^2 w dx = 0. \quad (4)$$

By definition,

$$\int \phi_0^2 w dx = 1, \quad (5)$$

so

$$a_{10} = - \int u_1 \phi_0 w dx. \quad (6)$$

The first orthogonalized function is therefore

$$\psi_1 = u_1(x) - \left[ \int u_1 \phi_0 w dx \right] \phi_0, \quad (7)$$

and the corresponding normalized function is

$$\phi_1 = \frac{\psi_1(x)}{\sqrt{\int \psi_1^2 w dx}}. \quad (8)$$

By mathematical induction, it follows that

$$\phi_i(x) = \frac{\psi_i(x)}{\sqrt{\int \psi_i^2 w dx}}, \quad (9)$$

where

$$\psi_i(x) = u_i + a_{i0}\phi_0 + a_{i1}\phi_1 + \dots + a_{i,i-1}\phi_{i-1} \quad (10)$$

and

$$a_{ij} \equiv - \int u_i \phi_j w dx. \quad (11)$$

If the functions are normalized to  $N_j$  instead of 1, then

$$\int_a^b [\phi_j(x)]^2 w dx = N_j^2 \quad (12)$$

$$\phi_i(x) = N_i \frac{\psi_i(x)}{\sqrt{\int \psi_i^2 w dx}} \quad (13)$$

$$a_{ij} = - \frac{\int u_i \phi_j w dx}{N_j^2}. \quad (14)$$

ORTHOGONAL POLYNOMIALS are especially easy to generate using GRAM-SCHMIDT ORTHONORMALIZATION. Use the notation

$$\langle x_i | x_j \rangle \equiv \langle x_i | w | x_j \rangle \equiv \int_a^b x_i(x) x_j(x) w(x) dx, \quad (15)$$

where  $w(x)$  is a WEIGHTING FUNCTION, and define the first few POLYNOMIALS,

$$p_0(x) \equiv 1 \quad (16)$$

$$p_1(x) = \left[ x - \frac{\langle x p_0 | p_0 \rangle}{\langle p_0 | p_0 \rangle} \right] p_0. \quad (17)$$

As defined,  $p_0$  and  $p_1$  are ORTHOGONAL POLYNOMIALS, as can be seen from

$$\begin{aligned} \langle p_0 | p_1 \rangle &= \left\langle \left[ x - \frac{\langle x p_0 | p_0 \rangle}{\langle p_0 | p_0 \rangle} \right] p_0 \right\rangle \\ &= \langle x p_0 \rangle - \frac{\langle x p_0 | p_0 \rangle}{\langle p_0 | p_0 \rangle} \langle p_0 \rangle \\ &= \langle x p_0 \rangle - \langle x p_0 \rangle = 0. \end{aligned} \quad (18)$$

Now use the RECURRENCE RELATION

$$p_{i+1}(x) = \left[ x - \frac{\langle x p_i | p_i \rangle}{\langle p_i | p_i \rangle} \right] p_i - \left[ \frac{\langle p_i | p_i \rangle}{\langle p_{i-1} | p_{i-1} \rangle} \right] p_{i-1} \quad (19)$$

to construct all higher order POLYNOMIALS.

To verify that this procedure does indeed produce ORTHOGONAL POLYNOMIALS, examine

$$\begin{aligned} \langle p_{i+1} | p_i \rangle &= \left\langle \left[ x - \frac{\langle x p_i | p_i \rangle}{\langle p_i | p_i \rangle} \right] p_i \middle| p_i \right\rangle \\ &\quad - \left\langle \frac{\langle p_i | p_i \rangle}{\langle p_{i-1} | p_{i-1} \rangle} p_{i-1} \middle| p_i \right\rangle \\ &= \langle x p_i | p_i \rangle - \frac{\langle x p_i | p_i \rangle}{\langle p_i | p_i \rangle} \langle p_i | p_i \rangle \\ &\quad - \frac{\langle p_i | p_i \rangle}{\langle p_{i-1} | p_{i-1} \rangle} \langle p_{i-1} | p_i \rangle \\ &= - \frac{\langle p_i | p_i \rangle}{\langle p_{i-1} | p_{i-1} \rangle} \langle p_{i-1} | p_i \rangle \\ &= - \frac{\langle p_i | p_i \rangle}{\langle p_{i-1} | p_{i-1} \rangle} \left[ - \frac{\langle p_{i-1} | p_{j-1} \rangle}{\langle p_{j-2} | p_{j-2} \rangle} \langle p_{j-2} | p_{j-1} \rangle \right] \\ &= \dots = (-1)^j \frac{\langle p_j | p_j \rangle}{\langle p_0 | p_0 \rangle} \langle p_0 | p_1 \rangle = 0, \end{aligned} \quad (20)$$

since  $\langle p_0 | p_1 \rangle = 0$ . Therefore, all the POLYNOMIALS  $p_i(x)$  are orthogonal. Many common ORTHOGONAL POLYNOMIALS of mathematical physics can be generated in this manner. However, the process is numerically unstable (Golub and van Loan 1989).

#### Gram Series

$$R(x) = 1 + \sum_{k=1}^{\infty} \frac{(\ln x)^k}{kk! \zeta(k+1)},$$

where  $\zeta$  is the RIEMANN ZETA FUNCTION. This approximation to the PRIME COUNTING FUNCTION is 10 times better than  $\text{Li}(x)$  for  $x < 10^9$  but has been proven to be worse infinitely often by Littlewood (Ingham 1990). An equivalent formulation due to Ramanujan is

$$G(x) \equiv \frac{4}{\pi} \sum_{k=1}^{\infty} \frac{(-1)^{k-1} k}{B_{2k}(2k-1)} \left( \frac{\ln x}{2\pi} \right)^{2k-1} \sim \pi(x)$$

(Berndt 1994), where  $B_{2k}$  is a BERNOULLI NUMBER. The integral analog, also found by Ramanujan, is

$$J(x) \equiv \int_0^{\infty} \frac{(\ln x)^t dt}{t\Gamma(t+1)\zeta(t+1)} \sim \pi(x)$$

(Berndt 1994).

#### Granny Knot

A COMPOSITE KNOT of seven crossings consisting of a KNOT SUM of TREFOILS. The granny knot has the same ALEXANDER POLYNOMIAL  $(x^2 - x + 1)^2$  as the SQUARE KNOT.

#### Graph (Function)

Technically, the graph of a function is its RANGE (a.k.a. image). Informally, given a FUNCTION  $f(x_1, \dots, x_n)$  defined on a DOMAIN  $U$ , the graph of  $f$  is defined as a CURVE or SURFACE showing the values taken by  $f$  over  $U$  (or some portion of  $U$ ),

$$\text{graph } f(x) \equiv \{(x, F(x)) \in \mathbb{R}^2 : x \in U\}$$

$$\text{graph } f(x_1, \dots, x_n) \equiv \{(x_1, \dots, x_n, f(x_1, \dots, x_n)) \in \mathbb{R}^{n+1} : (x_1, \dots, x_n) \in U\}.$$

A graph is sometimes also called a PLOT.

Good routines for plotting graphs use adaptive algorithms which plot more points in regions where the function varies most rapidly (Wagon 1991, Math Works 1992, Heck 1993, Wickham-Jones 1994).

#### Graph (Graph Theory)

A mathematical object composed of points known as VERTICES or NODES and lines connecting some (possibly empty) SUBSET of them, known as EDGES. The study of graphs is known as GRAPH THEORY. Graphs are 1-D COMPLEXES, and there are always an EVEN number of ODD NODES in a graph. The number of nonisomorphic graphs with  $v$  NODES is given by the PÓLYA ENUMERATION THEOREM. The first few values for  $n = 1, 2, \dots$ , are 1, 2, 4, 11, 34, 156, 1044, ... (Sloane's A000088; see above figure).

Graph sums, differences, powers, and products can be defined, as can graph eigenvalues.

Before applying PÓLYA ENUMERATION THEOREM, define the quantity

$$h_j = \frac{p!}{\prod_{i=1}^p i^{j_i} j_i!}, \quad (1)$$

where  $p!$  is the FACTORIAL of  $p$ , and the related polynomial

$$Z_p(S) = \sum_i h_{j_i} \prod_{k=1}^p f_k^{(j_i)_k}, \quad (2)$$

where the  $j_i = (j_1, \dots, j_p)_i$  are all of the  $p$ -VECTORS satisfying

$$j_1 + 2j_2 + 3j_3 + \dots + pj_p = p. \quad (3)$$

For example, for  $p = 3$ , the three possible values of  $j$  are

$$j_1 = (3, 0, 0), \text{ since } (1 \cdot 3) + (2 \cdot 0) + (3 \cdot 0) = 3,$$

$$\text{giving } h_{j_1} = \frac{3!}{(1^3 3!)(2^0 0!)(3^0 0!)} = 1 \quad (4)$$

$$j_2 = (1, 1, 0), \text{ since } (1 \cdot 1) + (2 \cdot 1) + (3 \cdot 0) = 3,$$

$$\text{giving } h_{j_2} = \frac{3!}{(1^1 1!)(2^1 1!)(3^0 0!)} = 3, \quad (5)$$

$$j_3 = (0, 0, 1), \text{ since } (1 \cdot 0) + (2 \cdot 0) + (3 \cdot 1) = 3$$

$$\text{giving } h_{j_3} = \frac{3!}{(1^0 0!)(2^0 0!)(3^1 1!)} = 2. \quad (6)$$

Therefore,

$$Z_3(S) = f_1^3 + 3f_1 f_2 + 2f_3. \quad (7)$$

For small  $p$ , the first few values of  $Z_p(S)$  are given by

$$Z_2(S) = f_1^2 + f_2 \quad (8)$$

$$Z_3(S) = f_1^3 + 3f_1 f_2 + 2f_3 \quad (9)$$

$$Z_4(S) = f_1^4 + 6f_1^2 f_2 + 3f_2^2 + 8f_1 f_3 + 6f_4 \quad (10)$$

$$Z_5(S) = f_1^5 + 10f_1^3 f_2 + 15f_1 f_2^2 + 20f_1^2 f_3 + 20f_2 f_3 + 30f_1 f_4 + 24f_5 \quad (11)$$

$$Z_6(S) = f_1^6 + 15f_1^4 f_2 + 45f_1^2 f_2^2 + 15f_2^3 + 40f_1^3 f_3 + 120f_1 f_2 f_3 + 40f_3^2 + 90f_1^2 f_4 + 90f_2 f_4 + 144f_1 f_5 + 120f_6 \quad (12)$$

$$Z_7(S) = f_1^7 + 21f_1^5 f_2 + 105f_1^3 f_2^2 + 105f_1 f_2^3 + 70f_1^4 f_3 + 420f_1^2 f_2 f_3 + 210f_2^2 f_3 + 280f_1 f_3^2 + 210f_1^3 f_4 + 630f_1 f_2 f_4 + 420f_3 f_4 + 504f_1^2 f_5 + 504f_2 f_5 + 840f_1 f_6 + 720f_7. \quad (13)$$

Application of the PÓLYA ENUMERATION THEOREM then gives the formula

$$Z(R) = \frac{1}{p!} \sum_{(j)} h_j \prod_{n=0}^{\lfloor (p-1)/2 \rfloor} g_{2n+1}^{n j_{2n+1} + (2n+1) \binom{j_{2n+1}}{2}} \times \prod_{n=1}^{\lfloor p/2 \rfloor} [(g_n g_{2n})^{n-1}]^{j_{2n}} g_{2n}^{2n \binom{j_{2n}}{2}} \times \prod_{q=1}^p \prod_{r=q+1}^p g_{\text{LCM}(q,r)}^{j_q j_r \text{GCD}(q,r)}, \quad (14)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION,  $\binom{n}{m}$  is a BINOMIAL COEFFICIENT, LCM is the LEAST COMMON MULTIPLE, GCD is the GREATEST COMMON DIVISOR, and the SUM ( $j$ ) is over all  $j_i$  satisfying the sum identity described above. The first few generating functions  $Z_p(R)$  are

$$Z_2(R) = 2g_1 \quad (15)$$

$$Z_3(R) = g_1^3 + 3g_1 g_2 + 2g_3 \quad (16)$$

$$Z_4(R) = g_1^6 + 9g_1^2 g_2^2 + 8g_3^2 + 6g_2 g_4 \quad (17)$$

$$Z_5(R) = g_1^{10} + 10g_1^4 g_2^3 + 15g_1^2 g_2^4 + 20g_1 g_3^3 + 30g_2 g_4^2 + 24g_5^2 + 20g_1 g_3 g_6 \quad (18)$$

$$Z_6(R) = g_1^{15} + 15g_1^7 g_2^4 + 60g_1^3 g_2^6 + 40g_1^3 g_3^4 + 40g_3^5 + 180g_1 g_2 g_4^3 + 144g_5^3 + 120g_1 g_2 g_3^2 g_6 + 120g_3 g_6^2 \quad (19)$$

$$Z_7(R) = g_1^{21} + 21g_1^{11} g_2^5 + 105g_1^5 g_2^8 + 105g_1^3 g_2^9 + 70g_1^6 g_3^5 + 280g_3^7 + 210g_1^3 g_2 g_4^4 + 630g_1 g_2^2 g_4^4 + 504g_1 g_5^4 + 420g_1^2 g_2^2 g_3^3 g_6 + 210g_1^2 g_2^2 g_3 g_6^2 + 840g_3 g_6^3 + 720g_7^3 + 504g_1 g_5^2 g_{10} + 420g_2 g_3 g_4 g_{12}. \quad (20)$$

Letting  $g_i = 1 + x^i$  then gives a POLYNOMIAL  $S_i(x)$ , which is a GENERATING FUNCTION for (i.e., the terms of  $x^i$  give) the number of graphs with  $i$  EDGES. The total number of graphs having  $i$  edges is  $S_i(1)$ . The first few  $S_i(x)$  are

$$S_2 = 1 + x \quad (21)$$

$$S_3 = 1 + x + x^2 + x^3 \quad (22)$$

$$S_4 = 1 + x + 2x^2 + 3x^3 + 2x^4 + x^5 + x^6 \quad (23)$$

$$S_5 = 1 + x + 2x^2 + 4x^3 + 6x^4 + 6x^5 + 6x^6 + 4x^7 + 2x^8 + x^9 + x^{10} \quad (24)$$

$$S_6 = 1 + x + 2x^2 + 5x^3 + 9x^4 + 15x^5 + 21x^6 + 24x^7 + 24x^8 + 21x^9 + 15x^{10} + 9x^{11} + 5x^{12} + 2x^{13} + x^{14} + x^{15} \quad (25)$$

$$S_7 = 1 + x + 2x^2 + 5x^3 + 10x^4 + 21x^5 + 21x^6 + 24x^7 + 41x^8 + 65x^9 + 97x^{10}$$

$$\begin{aligned}
&+ 131x^9 + 148x^{10} + 148x^{11} \\
&+ 131x^{12} + 97x^{13} + 65x^{14} + 41x^{15} \\
&+ 21x^{16} + 10x^{17} + 5x^{18} + 2x^{19} + x^{20} + x^{21},
\end{aligned}
\tag{26}$$

giving the number of graphs with  $n$  nodes as 1, 2, 4, 11, 34, 156, 1044, ... (Sloane's A000088). King and Palmer (cited in Read 1981) have calculated  $S_n$  up to  $n = 24$ , for which

$$\begin{aligned}
S_{24} = &195, 704, 906, 302, 078, 447, 922, 174, 862, 416, \dots \\
&\dots 726, 256, 004, 122, 075, 267, 063, 365, 754, 368.
\end{aligned}
\tag{27}$$

#### Graph Two-Coloring

Assignment of each EDGE of a GRAPH to one of two color classes ("red" or "green").

see also BLUE-EMPTY GRAPH, MONOCHROMATIC FORCED TRIANGLE

**Graphical Partition**

A graphical partition of order  $n$  is the DEGREE SEQUENCE of a GRAPH with  $n/2$  EDGES and no isolated VERTICES. For  $n = 2, 4, 6, \dots$ , the number of graphical partitions is 1, 2, 5, 9, 17, ... (Sloane's A000569).

**Grassmann Algebra**

see EXTERIOR ALGEBRA

**Grassmann Coordinates**

An  $(m+1)$ -D SUBSPACE  $W$  of an  $(n+1)$ -D VECTOR SPACE  $V$  can be specified by an  $(m+1) \times (n+1)$  MATRIX whose rows are the coordinates of a BASIS of  $W$ . The set of all  $\binom{n+1}{m+1}$   $(m+1) \times (m+1)$  MINORS of this MATRIX are then called the Grassmann coordinates of  $w$  (where  $\binom{a}{b}$  is a BINOMIAL COEFFICIENT).

see also CHOW COORDINATES

**References**

- Wilson, W. S.; Chern, S. S.; Abhyankar, S. S.; Lang, S.; and Igusa, J.-I. "Wei-Liang Chow." *Not. Amer. Math. Soc.* **43**, 1117–1124, 1996.

**Grassmann Manifold**

A special case of a FLAG MANIFOLD. A Grassmann manifold is a certain collection of vector SUBSPACES of a VECTOR SPACE. In particular,  $G_{n,k}$  is the Grassmann manifold of  $k$ -dimensional subspaces of the VECTOR SPACE  $\mathbb{R}^n$ . It has a natural MANIFOLD structure as an orbit-space of the STIEFEL MANIFOLD  $V_{n,k}$  of orthonormal  $k$ -frames in  $\mathbb{R}^n$ . One of the main things about Grassmann manifolds is that they are classifying spaces for VECTOR BUNDLES.

**Gray Code**

An encoding of numbers so that adjacent numbers have a single DIGIT differing by 1. A BINARY Gray code with  $n$  DIGITS corresponds to a HAMILTONIAN PATH on an  $n$ -D HYPERCUBE (including direction reversals). The term Gray code is often used to refer to a "reflected" code, or more specifically still, the binary reflected Gray code.

To convert a BINARY number  $d_1 d_2 \dots d_{n-1} d_n$  to its corresponding binary reflected Gray code, start at the right with the digit  $d_n$  (the  $n$ th, or last, DIGIT). If the  $d_{n-1}$  is 1, replace  $d_n$  by  $1 - d_n$ ; otherwise, leave it unchanged. Then proceed to  $d_{n-1}$ . Continue up to the first DIGIT

$d_1$ , which is kept the same since  $d_0$  is assumed to be a 0. The resulting number  $g_1 g_2 \dots g_{n-1} g_n$  is the reflected binary Gray code.

To convert a binary reflected Gray code  $g_1 g_2 \dots g_{n-1} g_n$  to a BINARY number, start again with the  $n$ th digit, and compute

$$\Sigma_n \equiv \sum_{i=1}^{n-1} g_i \pmod{2}.$$

If  $\Sigma_n$  is 1, replace  $g_n$  by  $1 - g_n$ ; otherwise, leave it the unchanged. Next compute

$$\Sigma_{n-1} \equiv \sum_{i=1}^{n-2} g_i \pmod{2},$$

and so on. The resulting number  $d_1 d_2 \dots d_{n-1} d_n$  is the BINARY number corresponding to the initial binary reflected Gray code.

The code is called reflected because it can be generated in the following manner. Take the Gray code 0, 1. Write it forwards, then backwards: 0, 1, 1, 0. Then append 0s to the first half and 1s to the second half: 00, 01, 11, 10. Continuing, write 00, 01, 11, 10, 10, 11, 01, 00 to obtain: 000, 001, 011, 010, 110, 111, 101, 100, ... (Sloane's A014550). Each iteration therefore doubles the number of codes. The Gray codes corresponding to the first few nonnegative integers are given in the following table.

0	0	20	11110	40	111100
1	1	21	11111	41	111101
2	11	22	11101	42	111111
3	10	23	11100	43	111110
4	110	24	10100	44	111010
5	111	25	10101	45	111011
6	101	26	10111	46	111001
7	100	27	10110	47	111000
8	1100	28	10010	48	101000
9	1101	29	10011	49	101001
10	1111	30	10001	50	101011
11	1110	31	10000	51	101010
12	1010	32	110000	52	101110
13	1011	33	110001	53	101111
14	1001	34	110011	54	101101
15	1000	35	110010	55	101100
16	11000	36	110110	56	100100
17	11001	37	110111	57	100101
18	11011	38	110101	58	100111
19	11010	39	110100	59	100110

The binary reflected Gray code is closely related to the solution of the TOWERS OF HANOI as well as the BAGUENAUDIER.

## Great Circle

The shortest path between two points on a SPHERE, also known as an ORTHODROME. To find the great circle (GEODESIC) distance between two points located at LATITUDE  $\delta$  and LONGITUDE  $\lambda$  of  $(\delta_1, \lambda_1)$  and  $(\delta_2, \lambda_2)$  on a SPHERE of RADIUS  $a$ , convert SPHERICAL COORDINATES to CARTESIAN COORDINATES using

$$\mathbf{r}_i = a \begin{bmatrix} \cos \lambda_i \cos \delta_i \\ \sin \lambda_i \cos \delta_i \\ \sin \delta_i \end{bmatrix}. \quad (1)$$

(Note that the LATITUDE  $\delta$  is related to the COLATITUDE  $\phi$  of SPHERICAL COORDINATES by  $\delta = 90^\circ - \phi$ , so the conversion to CARTESIAN COORDINATES replaces  $\sin \phi$  and  $\cos \phi$  by  $\cos \delta$  and  $\sin \delta$ , respectively.) Now find the ANGLE  $\alpha$  between  $\mathbf{r}_1$  and  $\mathbf{r}_2$  using the DOT PRODUCT,

$$\begin{aligned} \cos \alpha &= \hat{\mathbf{r}}_1 \cdot \hat{\mathbf{r}}_2 \\ &= \cos \delta_1 \cos \delta_2 (\sin \lambda_1 \sin \lambda_2 + \cos \lambda_1 \cos \lambda_2) \\ &\quad + \sin \delta_1 \sin \delta_2 \\ &= \cos \delta_1 \cos \delta_2 \cos(\lambda_1 - \lambda_2) + \sin \delta_1 \sin \delta_2. \end{aligned} \quad (2)$$

The great circle distance is then

$$d = a \cos^{-1} [\cos \delta_1 \cos \delta_2 \cos(\lambda_1 - \lambda_2) + \sin \delta_1 \sin \delta_2]. \quad (3)$$

For the Earth, the equatorial RADIUS is  $a \approx 6378$  km, or 3963 (statute) miles. Unfortunately, the FLATTENING of the Earth cannot be taken into account in this simple derivation, since the problem is considerable more complicated for a SPHEROID or ELLIPSOID (each of which has a RADIUS which is a function of LATITUDE).

The equation of the great circle can be explicitly computed using the GEODESIC formalism. Writing

$$u = \lambda \quad (4)$$

$$v = \delta = \frac{1}{2}\pi - \phi \quad (5)$$

gives the  $P$ ,  $Q$ , and  $R$  parameters of the GEODESIC (which are just combinations of the PARTIAL DERIVATIVES) as

$$P \equiv \left( \frac{\partial x}{\partial u} \right)^2 + \left( \frac{\partial y}{\partial u} \right)^2 + \left( \frac{\partial z}{\partial u} \right)^2 = a^2 \sin^2 v \quad (6)$$

$$Q \equiv \frac{\partial x}{\partial u} \frac{\partial x}{\partial v} + \frac{\partial y}{\partial u} \frac{\partial y}{\partial v} + \frac{\partial z}{\partial u} \frac{\partial z}{\partial v} = 0 \quad (7)$$

$$R \equiv \left( \frac{\partial x}{\partial v} \right)^2 + \left( \frac{\partial y}{\partial v} \right)^2 + \left( \frac{\partial z}{\partial v} \right)^2 = a^2. \quad (8)$$

The GEODESIC differential equation then becomes

$$\cos v \sin^4 v + 2 \cos v \sin^2 v v'^2 + \cos v v'^4 - \sin v v'' = 0. \quad (9)$$

However, because this is a special case of  $Q = 0$  with  $P$  and  $R$  explicit functions of  $v$  only, the GEODESIC solution takes on the special form

$$\begin{aligned} v &= c_1 \int \sqrt{\frac{R}{P^2 - c_1^2 P}} dv = c_1 \int \frac{dv}{a^2 \sin^4 v - c_1^2 \sin^2 v} \\ &= \int \frac{dv}{\sin v \sqrt{\left(\frac{a}{c_1}\right)^2 \sin^2 v - 1}} \\ &= -\tan^{-1} \left[ \frac{\cos v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} \right] + c_2 \end{aligned} \quad (10)$$

(Gradshteyn and Ryzhik 1979, p. 174, eqn. 2.599.6), which can be rewritten as

$$v = -\sin^{-1} \left( \frac{\cot v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} \right) + c_2. \quad (11)$$

It therefore follows that

$$(\sin c_2) a \sin v \cos u - (\cos c_2) a \sin v \sin u - \frac{a \cos v}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} = 0. \quad (12)$$

This equation can be written in terms of the CARTESIAN COORDINATES as

$$x \sin c_2 - y \cos c_2 - \frac{z}{\sqrt{\left(\frac{a}{c_1}\right)^2 - 1}} = 0, \quad (13)$$

which is simply a PLANE passing through the center of the SPHERE and the two points on the surface of the SPHERE.

**Great Rhombicuboctahedron (Archimedean)**

An ARCHIMEDEAN SOLID sometimes (improperly) called the TRUNCATED CUBOCTAHEDRON and also called the RHOMBITRUNCATED CUBOCTAHEDRON. Its DUAL is the DISDYAKIS DODECAHEDRON, also called the HEXAKIS OCTAHEDRON. It has SCHLÄFLI SYMBOL  $t\left\{\frac{3}{4}\right\}$ . It is also UNIFORM POLYHEDRON  $U_{11}$  and has WYTHOFF SYMBOL  $2\ 3\ 4$ . Its faces are  $8\{6\} + 12\{4\} + 6\{8\}$ . The SMALL CUBICUBOCTAHEDRON is a FACETED version. The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for unit edge length are

$$r = \frac{3}{97}(14 + \sqrt{2})\sqrt{13 + 6\sqrt{2}} \approx 2.20974$$

$$\rho = \frac{1}{2}\sqrt{12 + 6\sqrt{2}} \approx 2.26303$$

$$R = \frac{1}{2}\sqrt{13 + 6\sqrt{2}} \approx 2.31761.$$

Additional quantities are

$$t = \tan\left(\frac{1}{8}\pi\right) = \sqrt{2} - 1$$

$$l = 2t = 2(\sqrt{2} - 1)$$

$$h = 1 + l\sin\left(\frac{1}{4}\pi\right) = 3 - \sqrt{2}.$$

### Greater

A quantity  $a$  is said to be greater than  $b$  if  $a$  is larger than  $b$ , written  $a > b$ . If  $a$  is greater than or EQUAL to  $b$ , the relationship is written  $a \geq b$ . If  $a$  is MUCH GREATER than  $b$ , this is written  $a \gg b$ . Statements involving greater than and LESS than symbols are called INEQUALITIES.

see also EQUAL, GREATER THAN/LESS THAN SYMBOL, INEQUALITY, LESS, MUCH GREATER

### Greater Than/Less Than Symbol

When applied to a system possessing a length  $R$  at which solutions in a variable  $r$  change character (such as the gravitational field of a sphere as  $r$  runs from the interior to the exterior), the symbols

$$r_{>} \equiv \max(r, R)$$

$$r_{<} \equiv \min(r, R)$$

are sometimes used.

see also EQUAL, GREATER, LESS

**Greatest Common Denominator**

see GREATEST COMMON DIVISOR

**Greatest Common Divisor**

The greatest common divisor of  $a$  and  $b$   $\text{GCD}(a, b)$ , sometimes written  $(a, b)$ , is the largest DIVISOR common to  $a$  and  $b$ . Symbolically, let

$$a \equiv \prod_i p_i^{\alpha_i} \quad (1)$$

$$b \equiv \prod_i p_i^{\beta_i} \quad (2)$$

Then the greatest common divisor is given by

$$(a, b) = \prod_i p_i^{\min(\alpha_i, \beta_i)}, \quad (3)$$

where  $\min$  denotes the MINIMUM. The GCD is DISTRIBUTIVE

$$(ma, mb) = m(a, b) \quad (4)$$

$$(ma, mb, mc) = m(a, b, c), \quad (5)$$

and ASSOCIATIVE

$$(a, b, c) = ((a, b), c) = (a, (b, c)) \quad (6)$$

$$(ab, cd) = (a, c)(b, d) \left( \frac{a}{(a, c)}, \frac{d}{(b, d)} \right) \left( \frac{c}{(a, c)}, \frac{b}{(b, d)} \right). \quad (7)$$

If  $a = a_1(a, b)$  and  $b = b_1(a, b)$ , then

$$(a, b) = (a_1(a, b), b_1(a, b)) = (a, b)(a_1, b_1), \quad (8)$$

so  $(a_1, b_1) = 1$  and  $a_1$  and  $b_1$  are said to be RELATIVELY PRIME. The GCD is also IDEMPOTENT

$$(a, a) = a, \quad (9)$$

COMMUTATIVE

$$(a, b) = (b, a), \quad (10)$$

and satisfies the ABSORPTION LAW

$$[a, (a, b)] = a. \quad (11)$$

The probability that two INTEGERS picked at random are RELATIVELY PRIME is  $[\zeta(2)]^{-1} = 6/\pi^2$ , where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION. Polezzi (1997) observed that  $(m, n) = k$ , where  $k$  is the number of LATTICE POINTS in the PLANE on the straight LINE connecting the VECTORS  $(0, 0)$  and  $(m, n)$  (excluding  $(m, n)$  itself). This observation is intimately connected with the probability of obtaining RELATIVELY PRIME integers, and also with the geometric interpretation of a REDUCED FRACTION  $y/x$  as a string through a LATTICE of points with ends at  $(1, 0)$  and  $(x, y)$ . The pegs it presses against

$(x_i, y_i)$  give alternate CONVERGENTS  $y_i/x_i$  of the CONTINUED FRACTION for  $y/x$ , while the other CONVERGENTS are obtained from the pegs it presses against with the initial end at  $(0, 1)$ .

Knuth showed that

$$(2^p - 1, q^q - 1) = 2^{(p, q)} - 1 \quad (12)$$

for  $p, q$  PRIME.

The extended greatest common divisor of two INTEGERS  $m$  and  $n$  can be defined as the greatest common divisor of  $m$  and  $n$  which also satisfies the constraint  $g = rm + sn$  for  $r$  and  $s$  given INTEGERS. It is used in solving LINEAR DIOPHANTINE EQUATIONS.

## Grebe Point

see LEMOINE POINT

## Greedy Algorithm

An algorithm used to recursively construct a SET of objects from the smallest possible constituent parts.

Given a SET of  $k$  INTEGERS  $(a_1, a_2, \dots, a_k)$  with  $a_1 < a_2 < \dots < a_k$ , a greedy algorithm can be used to find a VECTOR of coefficients  $(c_1, c_2, \dots, c_k)$  such that

$$\sum_{i=1}^k c_i a_i = \mathbf{c} \cdot \mathbf{a} = n, \quad (1)$$

where  $\mathbf{c} \cdot \mathbf{a}$  is the DOT PRODUCT, for some given INTEGER  $n$ . This can be accomplished by letting  $c_i = 0$  for  $i = 1, \dots, k-1$  and setting

$$c_k = \left\lfloor \frac{n}{a_k} \right\rfloor. \quad (2)$$

Now define the difference between the representation and  $n$  as

$$\Delta \equiv n - \mathbf{c} \cdot \mathbf{a}. \quad (3)$$

If  $\Delta = 0$  at any step, a representation has been found. Otherwise, decrement the NONZERO  $a_i$  term with least  $i$ , set all  $a_j = 0$  for  $j < i$ , and build up the remaining terms from

$$c_j = \left\lfloor \frac{\Delta_j}{a_k} \right\rfloor \quad (4)$$

for  $j = i-1, \dots, 1$  until  $\Delta = 0$  or all possibilities have been exhausted.

For example, MCNUGGET NUMBERS are numbers which are representable using only  $(a_1, a_2, a_3) = (6, 9, 20)$ . Taking  $n = 62$  and applying the algorithm iteratively gives the sequence (0, 0, 3), (0, 2, 2), (2, 1, 2), (3, 0, 2), (1, 4, 1), at which point  $\Delta = 0$ . 62 is therefore a MCNUGGET NUMBER with

$$62 = (1 \cdot 6) + (4 \cdot 9) + (1 \cdot 20). \quad (5)$$

If any INTEGER  $n$  can be represented with  $c_i = 0$  or 1 using a sequence  $(a_1, a_2, \dots)$ , then this sequence is called a COMPLETE SEQUENCE.

A greedy algorithm can also be used to break down arbitrary fractions into UNIT FRACTIONS in a finite number of steps. For a FRACTION  $a/b$ , find the least INTEGER  $x_1$  such that  $1/x_1 \leq a/b$ , i.e.,

$$x_1 = \frac{\lceil b \rceil}{a}, \quad (6)$$

where  $\lceil x \rceil$  is the CEILING FUNCTION. Then find the least INTEGER  $x_2$  such that  $1/x_2 \leq a/b - 1/x_1$ . Iterate until there is no remainder. The ALGORITHM gives two or fewer terms for  $1/n$  and  $2/n$ , three or fewer terms for  $3/n$ , and four or fewer for  $4/n$ .

Paul Erdős and E. G. Strays have conjectured that the DIOPHANTINE EQUATION

$$\frac{4}{n} = \frac{1}{a} + \frac{1}{b} + \frac{1}{c} \quad (7)$$

always can be solved, and W. Sierpiński conjectured that

$$\frac{5}{n} = \frac{1}{a} + \frac{1}{b} + \frac{1}{c} \quad (8)$$

can be solved.

## Green's Function

Let

$$\tilde{L} = \tilde{D}^n + a_{n-1}(t)\tilde{D}^{n-1} + \dots + a_1(t)\tilde{D} + a_0(t) \quad (1)$$

be a differential OPERATOR in 1-D, with  $a_i(t)$  CONTINUOUS for  $i = 0, 1, \dots, n-1$  on the interval  $I$ , and assume we wish to find the solution  $y(t)$  to the equation

$$\tilde{L}y(t) = h(t), \quad (2)$$

where  $h(t)$  is a given CONTINUOUS on  $I$ . To solve equation (2), we look for a function  $g : C^n(I) \mapsto C(I)$  such that  $\tilde{L}(g(h)) = h$ , where

$$y(t) = g(h(t)). \quad (3)$$

This is a CONVOLUTION equation of the form

$$y = g * h, \quad (4)$$

so the solution is

$$y(t) = \int_{t_0}^t g(t-x)h(x) dx, \quad (5)$$

where the function  $g(t)$  is called the Green's function for  $\tilde{L}$  on  $I$ .

Now, note that if we take  $h(t) = \delta(t)$ , then

$$y(t) = \int_{t_0}^t g(t-x)\delta(x) dx = g(t), \quad (6)$$

so the Green's function can be defined by

$$\tilde{L}g(t) = \delta(t). \quad (7)$$

However, the Green's function can be uniquely determined only if some initial or boundary conditions are given.

For an arbitrary linear differential operator  $\tilde{L}$  in 3-D, the Green's function  $G(\mathbf{r}, \mathbf{r}')$  is defined by analogy with the 1-D case by

$$\tilde{L}G(\mathbf{r}, \mathbf{r}') = \delta(\mathbf{r} - \mathbf{r}'). \quad (8)$$

The solution to  $\tilde{L}\phi = f$  is then

$$\phi(\mathbf{r}) = \int G(\mathbf{r}, \mathbf{r}') f(\mathbf{r}') d^3 \mathbf{r}'. \quad (9)$$

Explicit expressions for  $G(\mathbf{r}, \mathbf{r}')$  can often be found in terms of a basis of given eigenfunctions  $\phi_n(\mathbf{r}_1)$  by expanding the Green's function

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) \quad (10)$$

and DELTA FUNCTION,

$$\delta^3(\mathbf{r}_1 - \mathbf{r}_2) = \sum_{n=0}^{\infty} b_n \phi_n(\mathbf{r}_1). \quad (11)$$

Multiplying both sides by  $\phi_m(\mathbf{r}_2)$  and integrating over  $\mathbf{r}_1$  space,

$$\int \phi_m(\mathbf{r}_2) \delta^3(\mathbf{r}_1 - \mathbf{r}_2) d^3 \mathbf{r}_1 = \sum_{n=0}^{\infty} b_n \int \phi_m(\mathbf{r}_2) \phi_n(\mathbf{r}_1) d^3 \mathbf{r}_1 \quad (12)$$

$$\phi_m(\mathbf{r}_2) = \sum_{n=0}^{\infty} b_n \delta_{nm} = b_m, \quad (13)$$

so

$$\delta^3(\mathbf{r}_1 - \mathbf{r}_2) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2). \quad (14)$$

By plugging in the differential operator, solving for the  $a_n$ s, and substituting into  $G$ , the original nonhomogeneous equation then can be solved.

#### References

Arfken, G. "Nonhomogeneous Equation—Green's Function," "Green's Functions—One Dimension," and "Green's Functions—Two and Three Dimensions." §8.7 and §16.5–16.6 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 480–491 and 897–924, 1985.

#### Green's Function—Helmholtz Differential Equation

The inhomogeneous HELMHOLTZ DIFFERENTIAL EQUATION is

$$\nabla^2 \psi(\mathbf{r}) + k^2 \psi(\mathbf{r}) = \rho(\mathbf{r}), \quad (1)$$

where the Helmholtz operator is defined as  $\tilde{L} \equiv \nabla^2 + k^2$ . The Green's function is then defined by

$$(\nabla^2 + k^2)G(\mathbf{r}_1, \mathbf{r}_2) = \delta^3(\mathbf{r}_1 - \mathbf{r}_2). \quad (2)$$

Define the basis functions  $\phi_n$  as the solutions to the homogeneous HELMHOLTZ DIFFERENTIAL EQUATION

$$\nabla^2 \phi_n(\mathbf{r}) + k_n^2 \phi_n(\mathbf{r}) = 0. \quad (3)$$

The Green's function can then be expanded in terms of the  $\phi_n$ s,

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1), \quad (4)$$

and the DELTA FUNCTION as

$$\delta^3(\mathbf{r}_1 - \mathbf{r}_2) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2). \quad (5)$$

Plugging (4) and (5) into (2) gives

$$\begin{aligned} \nabla^2 \left[ \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) \right] + k^2 \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) \\ = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2). \end{aligned} \quad (6)$$

Using (3) gives

$$\begin{aligned} - \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) k_n^2 \phi_n(\mathbf{r}_1) + k^2 \sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) \\ = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2) \end{aligned} \quad (7)$$

$$\sum_{n=0}^{\infty} a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) (k^2 - k_n^2) = \sum_{n=0}^{\infty} \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2). \quad (8)$$

This equation must hold true for each  $n$ , so

$$a_n(\mathbf{r}_2) \phi_n(\mathbf{r}_1) (k^2 - k_n^2) = \phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2) \quad (9)$$

$$a_n(\mathbf{r}_2) = \frac{\phi_n(\mathbf{r}_2)}{k^2 - k_n^2}, \quad (10)$$

and (4) can be written

$$G(\mathbf{r}_1, \mathbf{r}_2) = \sum_{n=0}^{\infty} \frac{\phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2)}{k^2 - k_n^2}. \quad (11)$$

The general solution to (1) is therefore

$$\begin{aligned} \psi(\mathbf{r}_1) &= \int G(\mathbf{r}_1, \mathbf{r}_2) \rho(\mathbf{r}_2) d^3 \mathbf{r}_2 \\ &= \sum_{n=0}^{\infty} \int \frac{\phi_n(\mathbf{r}_1) \phi_n(\mathbf{r}_2) \rho(\mathbf{r}_2)}{k^2 - k_n^2} d^3 \mathbf{r}_2. \end{aligned} \quad (12)$$

#### References

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 529–530, 1985.

#### Green's Function—Poisson's Equation

POISSON'S EQUATION equation is

$$\nabla^2 \phi = 4\pi\rho, \quad (1)$$

where  $\phi$  is often called a potential function and  $\rho$  a density function, so the differential operator in this case is  $\tilde{L} = \nabla^2$ . As usual, we are looking for a Green's function  $G(\mathbf{r}_1, \mathbf{r}_2)$  such that

$$\nabla^2 G(\mathbf{r}_1, \mathbf{r}_2) = \delta^3(\mathbf{r}_1 - \mathbf{r}_2). \quad (2)$$

But from LAPLACIAN,

$$\nabla^2 \left( \frac{1}{|\mathbf{r} - \mathbf{r}'|} \right) = -4\pi\delta^3(\mathbf{r} - \mathbf{r}'), \quad (3)$$

so

$$G(\mathbf{r}, \mathbf{r}') = -\frac{1}{4\pi|\mathbf{r} - \mathbf{r}'|}, \quad (4)$$

and the solution is

$$\phi(\mathbf{r}) = \int G(\mathbf{r}, \mathbf{r}') [4\pi\rho(\mathbf{r}')] d^3 \mathbf{r}' = - \int \frac{\rho(\mathbf{r}') d^3 \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|}. \quad (5)$$

Expanding  $G(\mathbf{r}_1, \mathbf{r}_2)$  in the SPHERICAL HARMONICS  $Y_l^m$  gives

$G(\mathbf{r}_1, \mathbf{r}_2)$

$$= \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{1}{2l+1} \frac{r_{<}^l}{r_{>}^{l+1}} Y_l^m(\theta_1, \phi_1) Y_l^{m*}(\theta_2, \phi_2), \quad (6)$$

where  $r_{<}$  and  $r_{>}$  are GREATER THAN/LESS THAN SYMBOLS. This expression simplifies to

$$G(\mathbf{r}_1, \mathbf{r}_2) = \frac{1}{4\pi} \sum_{l=0}^{\infty} \frac{r_{<}^l}{r_{>}^{l+1}} P_l(\cos \gamma), \quad (7)$$

where  $P_l$  are LEGENDRE POLYNOMIALS, and  $\cos \gamma \equiv \mathbf{r}_1 \cdot \mathbf{r}_2$ . Equations (6) and (7) give the addition theorem for LEGENDRE POLYNOMIALS.

In CYLINDRICAL COORDINATES, the Green's function is much more complicated,

$$\begin{aligned} G(\mathbf{r}_1, \mathbf{r}_2) &= \frac{1}{2\pi^2} \sum_{m=-\infty}^{\infty} \int_0^{\infty} I_m(k\rho_{<}) K_m(k\rho_{>}) e^{im(\phi_1 - \phi_2)} \cos[k(z_1 - z_2)] dk, \\ &\quad (8) \end{aligned}$$

where  $I_m(x)$  and  $K_m(x)$  are MODIFIED BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS (Arfken 1985).

#### References

Arfken, G. *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 485–486, 905, and 912, 1985.

#### Green's Identities

Green's identities are a set of three vector derivative/integral identities which can be derived starting with the vector derivative identities

$$\nabla \cdot (\psi \nabla \phi) = \psi \nabla^2 \phi + (\nabla \psi) \cdot (\nabla \phi) \quad (1)$$

and

$$\nabla \cdot (\phi \nabla \psi) = \phi \nabla^2 \psi + (\nabla \phi) \cdot (\nabla \psi), \quad (2)$$

where  $\nabla \cdot$  is the DIVERGENCE,  $\nabla$  is the GRADIENT,  $\nabla^2$  is the LAPLACIAN, and  $\mathbf{a} \cdot \mathbf{b}$  is the DOT PRODUCT. From the DIVERGENCE THEOREM,

$$\int_V (\nabla \cdot \mathbf{F}) dV = \int_S \mathbf{F} \cdot d\mathbf{a}. \quad (3)$$

Plugging (2) into (3),

$$\int_S \phi (\nabla \psi) \cdot d\mathbf{a} = \int_V [\phi \nabla^2 \psi + (\nabla \phi) \cdot (\nabla \psi)] dV. \quad (4)$$

This is Green's first identity.

Subtracting (2) from (1),

$$\nabla \cdot (\phi \nabla \psi - \psi \nabla \phi) = \phi \nabla^2 \psi - \psi \nabla^2 \phi. \quad (5)$$

Therefore,

$$\int_V (\phi \nabla^2 \psi - \psi \nabla^2 \phi) dV = \int_S (\phi \nabla \psi - \psi \nabla \phi) \cdot d\mathbf{a}. \quad (6)$$

This is Green's second identity.

Let  $u$  have continuous first PARTIAL DERIVATIVES and be HARMONIC inside the region of integration. Then Green's third identity is

$$u(x, y) = \frac{1}{2\pi} \oint_C \left[ \ln \left( \frac{1}{r} \right) \frac{\partial u}{\partial n} - u \frac{\partial}{\partial n} \ln \left( \frac{1}{r} \right) \right] ds \quad (7)$$

(Kaplan 1991, p. 361).

#### Greene's Method

A method for predicting the onset of widespread CHAOS. It is based on the hypothesis that the dissolution of an invariant torus can be associated with the sudden change from stability to instability of nearly closed orbits (Tabor 1989, p. 163).

see also OVERLAPPING RESONANCE METHOD

#### References

Tabor, M. *Chaos and Integrability in Nonlinear Dynamics: An Introduction*. New York: Wiley, 1989.

#### Green Space

A  $G$ -SPACE provides local notions of harmonic, hyperharmonic, and superharmonic functions. When there exists a nonconstant superharmonic function greater than 0, it is called a Green space. Examples are  $\mathbb{R}^n$  (for  $n \geq 3$ ) and any bounded domain of  $\mathbb{R}^n$ .

#### Green's Theorem

Green's theorem is a vector identity which is equivalent to the CURL THEOREM in the PLANE. Over a region  $D$  in the plane with boundary  $\partial D$ ,

$$\int_{\partial D} f(x, y) dx + g(x, y) dy = \iint_D \left( \frac{\partial g}{\partial x} - \frac{\partial f}{\partial y} \right) dx dy$$

$$\int_{\partial D} \mathbf{F} \cdot d\mathbf{s} = \iint_D (\nabla \times \mathbf{F}) \cdot \mathbf{k} dA.$$

If the region  $D$  is on the left when traveling around  $\partial D$ , then AREA of  $D$  can be computed using

$$A = \frac{1}{2} \int_{\partial D} x dy - y dx.$$

#### Gregory's Formula

A series FORMULA for  $\pi$  found by Gregory and Leibniz,

$$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \dots$$

It converges very slowly, but its convergence can be accelerated using certain transformations, in particular

$$\pi = \sum_{k=1}^{\infty} \frac{3^k - 1}{4^k} \zeta(k+1),$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION (Vardi 1991).

see also MACHIN'S FORMULA, MACHIN-LIKE FORMULAS,  $\pi$

#### References

Vardi, I. *Computational Recreations in Mathematica*. Reading, MA: Addison-Wesley, pp. 157–158, 1991.

#### Gregory Number

A number

$$t_x = \tan^{-1} \left( \frac{1}{x} \right) = \cot^{-1} x,$$

where  $x$  is an INTEGER or RATIONAL NUMBER,  $\tan^{-1} x$  is the INVERSE TANGENT, and  $\cot^{-1} x$  is the INVERSE COTANGENT. Gregory numbers arise in the determination of MACHIN-LIKE FORMULAS. Every Gregory number  $t_x$  can be expressed uniquely as a sum of  $t_n$ s where the  $n$ s are STØRMER NUMBERS.

#### Grenz-Formel

An equation derived by Kronecker:

$$\sum' (x^2 + y^2 + dz^2)^{-s} = 4\zeta(s)\eta(s) + \frac{2\pi}{s-1} \frac{\zeta(2s-2)}{d^{s-1}} + \frac{2\pi^s}{\Gamma(s)} d^{(1-s)/2} \sum_{n=1}^{\infty} n^{(s-1)/2} \sum_{u^2|n} \frac{r\left(\frac{n}{u^2}\right)}{u^{2s-2}} \int_0^{\infty} e^{\pi\sqrt{nd}(y+y^{-1})} y^{s-2} dy,$$

where

$$r(n) = 4 \sum_{d|n} \sin\left(\frac{1}{2}\pi d\right),$$

$\zeta(z)$ , is the RIEMANN ZETA FUNCTION,  $\eta(z)$  is the DIRICHLET ETA FUNCTION,  $\Gamma(z)$  is the GAMMA FUNCTION, and the primed sum omits infinite terms (Selberg and Chowla 1967).

### Griffiths Points

“The” Griffiths point is the fixed point in GRIFFITHS’ THEOREM. Given four points on a CIRCLE and a line through the center of the CIRCLE, the four corresponding Griffiths points are COLLINEAR (Tabov 1995).

The points

$$Gr = I + 4Ge$$

$$Gr' = I - 4Ge,$$

are known as the first and second Griffiths points, where  $I$  is the INCENTER and  $Ge$  is the GERGONNE POINT.

see also GERGONNE POINT, GRIFFITHS’ THEOREM, INCENTER, OLDKNOW POINTS, RIGBY POINTS

#### References

- Oldknow, A. “The Euler-Gergonne-Soddy Triangle of a Triangle.” *Amer. Math. Monthly* **103**, 319–329, 1996.  
 Tabov, J. “Four Collinear Griffiths Points.” *Math. Mag.* **68**, 61–64, 1995.

### Griffiths’ Theorem

When a point  $P$  moves along a line through the CIRCUMCENTER of a given TRIANGLE  $\Delta$ , the CIRCUMCIRCLE of the PEDAL TRIANGLE of  $P$  with respect to  $\Delta$  passes through a fixed point (the GRIFFITHS POINT) on the NINE-POINT CIRCLE of  $\Delta$ .

see also CIRCUMCENTER, GRIFFITHS POINTS, NINE-POINT CIRCLE, PEDAL TRIANGLE

### Grimm’s Conjecture

Grimm conjectures that if  $n + 1, n + 2, \dots, n + k$  are all COMPOSITE NUMBERS, then there are distinct PRIMES  $p_i$  such that  $p_i | (n + j)$  for  $1 \leq j \leq k$ .

#### References

- Guy, R. K. “Grimm’s Conjecture.” §B32 in *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, p. 86, 1994.

### Grinberg Formula

A formula satisfied by all HAMILTONIAN CIRCUITS with  $n$  nodes. Let  $f_j$  be the number of regions inside the circuit with  $j$  sides, and let  $g_j$  be the number of regions outside the circuit with  $j$  sides. If there are  $d$  interior diagonals, then there must be  $d + 1$  regions

$$[\# \text{ regions in interior}] = d + 1 = f_2 + f_3 + \dots + f_n. \quad (1)$$

Any region with  $j$  sides is bounded by  $j$  EDGES, so such regions contribute  $jf_j$  to the total. However, this counts each diagonal twice (and each EDGE only once). Therefore,

$$2f_2 + 3f_3 + \dots + nf_n = 2d + n. \quad (2)$$

Take  $(2) - 2 \times (1)$ ,

$$f_3 + 2f_4 + 3f_5 + \dots + (n - 2)f_n = n - 2. \quad (3)$$

Similarly,

$$g_3 + 2g_4 + \dots + (n - 2)g_n = n - 2, \quad (4)$$

so

$$(f_3 - g_3) + 2(f_4 - g_4) + 3(f_5 - g_5) + \dots + (n - 2)(f_n - g_n) = 0. \quad (5)$$

### Gröbner Basis

A Gröbner basis for a system of POLYNOMIAL equations is an equivalence system that possesses useful properties. It is very roughly analogous to computing an ORTHONORMAL BASIS from a set of BASIS VECTORS and can be described roughly as a combination of GAUSSIAN ELIMINATION (for linear systems) and the EUCLIDEAN ALGORITHM (for UNIVARIATE POLYNOMIALS over a FIELD).

Gröbner bases are useful in the construction of symbolic algebra algorithms. The algorithm for computing Gröbner bases is known as BUCHBERGER’S ALGORITHM.

see also BUCHBERGER’S ALGORITHM, COMMUTATIVE ALGEBRA

### Groemer Packing

A honeycomb-like packing that forms HEXAGONS.

see also GROEMER THEOREM

#### References

- Stewart, I. “A Bundling Fool Beats the Wrap.” *Sci. Amer.* **268**, 142–144, 1993.

**Groemer Theorem**

Given  $n$  CIRCLES and a PERIMETER  $p$ , the total AREA of the CONVEX HULL is

$$A_{\text{Convex Hull}} = 2\sqrt{3}(n-1) + p(1 - \frac{1}{2}\sqrt{3}) + \pi(\sqrt{3}-1).$$

Furthermore, the actual AREA equals this value IFF the packing is a GROEMER PACKING. The theorem was proved in 1960 by Helmut Groemer.

see also CONVEX HULL

**Gronwall's Theorem**

Let  $\sigma(n)$  be the DIVISOR FUNCTION. Then

$$\overline{\lim}_{n \rightarrow \infty} \frac{\sigma(n)}{n \ln \ln n} = e^\gamma,$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT. Ramanujan independently discovered a less precise version of this theorem (Berndt 1994). Robin (1984) showed that the validity of the inequality

$$\sigma(n) < e^\gamma n \ln \ln n$$

for  $n \geq 5041$  is equivalent to the RIEMANN HYPOTHESIS.

**Grothendieck's Majorant**

The best known majorant of Grothendieck's constant.

Let  $A$  be an  $n \times n$  REAL SQUARE MATRIX such that

$$\left| \sum_{1 \leq i, j \leq n} a_{ij} x_i y_j \right| \quad (1)$$

in which  $x_i$  and  $y_j$  have REAL ABSOLUTE VALUES  $< 1$ . Grothendieck has shown there exists a number  $K_G$  independent of  $A$  and  $n$  satisfying

$$\left| \sum_{1 \leq i, j \leq n} a_{ij} \langle x_i, y_j \rangle \right| \quad (2)$$

in which the vectors  $x_i$  and  $y_j$  have a norm  $< 1$  in HILBERT SPACE. The Grothendieck constant is the smallest REAL NUMBER for which this inequality has been proven. Krivine (1977) showed that

$$1.676\dots \leq K_G \leq 1.782\dots, \quad (3)$$

and has postulated that

$$K_G \equiv \frac{\pi}{2 \ln(1 + \sqrt{2})} = 1.7822139\dots \quad (4)$$

It is related to KHINTCHINE'S CONSTANT.

**Grothendieck's Theorem**

Let  $E$  and  $F$  be paired spaces with  $S$  a family of absolutely convex bounded sets of  $F$  such that the sets of  $S$  generate  $F$  and, if  $B_1, B_2 \in S$ , then there exists a  $B_3 \in S$  such that  $B_3 \supset B_1$  and  $B_3 \supset B_2$ . Then  $E_S$  is complete IFF algebraic linear functional  $f(y)$  of  $F$  that is weakly continuous on every  $B \in S$  is expressed as  $f(y) = \langle x, y \rangle$  for some  $x \in E$ . When  $E_S$  is not complete, the space of all linear functionals satisfying this condition gives the completion  $\hat{E}_S$  of  $E_S$ .

see also MACKEY'S THEOREM

**References**

### Ground Set

A PARTIALLY ORDERED SET is defined as an ordered pair  $P = (X, \leq)$ . Here,  $X$  is called the GROUND SET of  $P$  and  $\leq$  is the PARTIAL ORDER of  $P$ .

see also PARTIAL ORDER, PARTIALLY ORDERED SET

### Group

A group  $G$  is defined as a finite or infinite set of OPERANDS (called "elements")  $A, B, C, \dots$  that may be combined or "multiplied" via a BINARY OPERATOR to form well-defined products and which furthermore satisfy the following conditions:

1. Closure: If  $A$  and  $B$  are two elements in  $G$ , then the product  $AB$  is also in  $G$ .
2. Associativity: The defined multiplication is associative, i.e., for all  $A, B, C \in G$ ,  $(AB)C = A(BC)$ .
3. Identity: There is an IDENTITY ELEMENT  $I$  (a.k.a.  $1$ ,  $E$ , or  $e$ ) such that  $IA = AI = A$  for every element  $A \in G$ .
4. Inverse: There must be an inverse or reciprocal of each element. Therefore, the set must contain an element  $B = A^{-1}$  such that  $AA^{-1} = A^{-1}A = I$  for each element of  $G$ .

A group is therefore a MONOID for which every element is invertible. A group must contain at least one element.

The study of groups is known as GROUP THEORY. If there are a finite number of elements, the group is called a FINITE GROUP and the number of elements is called the ORDER of the group.

Since each element  $A, B, C, \dots, X$ , and  $Y$  is a member of the GROUP, GROUP property 1 requires that the product

$$D \equiv ABC \dots XY \quad (1)$$

must also be a member. Now apply  $D$  to  $Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1}$ ,

$$\begin{aligned} D(Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1}) \\ = (ABC \dots XY)(Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1}). \end{aligned} \quad (2)$$

But

$$\begin{aligned} ABC \dots XYY^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1} \\ = ABC \dots XIX^{-1} \dots C^{-1}B^{-1}A^{-1} \\ = ABC \dots C^{-1}B^{-1}A^{-1} = \dots = AA^{-1} = I, \end{aligned} \quad (3)$$

so

$$I = D(Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1}), \quad (4)$$

which means that

$$D^{-1} = Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1} \quad (5)$$

and

$$(ABC \dots XY)^{-1} = Y^{-1}X^{-1} \dots C^{-1}B^{-1}A^{-1}. \quad (6)$$

An IRREDUCIBLE REPRESENTATION of a group is a representation for which there exists no UNITARY TRANSFORMATION which will transform the representation MATRIX into block diagonal form. The IRREDUCIBLE REPRESENTATION has some remarkable properties. Let the ORDER of a GROUP be  $h$ , and the dimension of the  $i$ th representation (the order of each constituent matrix) be  $l_i$  (a POSITIVE INTEGER). Let any operation be denoted  $R$ , and let the  $m$ th row and  $n$ th column of the matrix corresponding to a matrix  $R$  in the  $i$ th IRREDUCIBLE REPRESENTATION be  $\Gamma_i(R)_{mn}$ . The following properties can be derived from the GROUP ORTHOGONALITY THEOREM,

$$\sum_R \Gamma_i(R)_{mn} \Gamma_j(R)_{m'n'}^* = \frac{h}{\sqrt{l_i l_j}} \delta_{ij} \delta_{mm'} \delta_{nn'}. \quad (7)$$

1. The DIMENSIONALITY THEOREM:

$$h = \sum_i l_i^2 = l_1^2 + l_2^2 + l_3^2 + \dots = \sum_i \chi_i^2(I), \quad (8)$$

where each  $l_i$  must be a POSITIVE INTEGER and  $\chi$  is the CHARACTER (trace) of the representation.

2. The sum of the squares of the CHARACTERS in any IRREDUCIBLE REPRESENTATION  $i$  equals  $h$ ,

$$h = \sum_R \chi_i^2(R). \quad (9)$$

3. ORTHOGONALITY of different representations

$$\sum_R \chi_i(R) \chi_j(R) = 0 \quad \text{for } i \neq j. \quad (10)$$

4. In a given representation, reducible or irreducible, the CHARACTERS of all MATRICES belonging to operations in the same class are identical (but differ from those in other representations).
5. The number of IRREDUCIBLE REPRESENTATIONS of a GROUP is equal to the number of CONJUGACY CLASSES in the GROUP. This number is the dimension of the  $\Gamma$  MATRIX (although some may have zero elements).
6. A one-dimensional representation with all 1s (totally symmetric) will always exist for any GROUP.
7. A 1-D representation for a GROUP with elements expressed as MATRICES can be found by taking the CHARACTERS of the MATRICES.
8. The number  $a_i$  of IRREDUCIBLE REPRESENTATIONS  $\chi_i$  present in a reducible representation  $c$  is given by

$$a_i = \frac{1}{h} \sum_R \chi(R) \chi_i(R), \quad (11)$$

where  $h$  is the ORDER of the GROUP and the sum must be taken over all elements in each class. Written explicitly,

$$a_i = \frac{1}{h} \sum_R \chi(R) \chi_i'(R) n_R, \quad (12)$$

where  $\chi_i'$  is the CHARACTER of a single entry in the CHARACTER TABLE and  $n_R$  is the number of elements in the corresponding CONJUGACY CLASS.

### Group Ring

The set of sums  $\sum_x a_x x$  ranging over a multiplicative GROUP and  $a_i$  are elements of a FIELD with all but a finite number of  $a_i = 0$ .

## Group Theory

The study of GROUPS. Gauss developed but did not publish parts of the mathematics of group theory, but Galois is generally considered to have been the first to develop the theory. Group theory is a powerful formal method for analyzing abstract and physical systems in which SYMMETRY is present and has surprising importance in physics, especially quantum mechanics.

## Groupoid

There are at least two definitions of "groupoid" currently in use.

The first type of groupoid is an algebraic structure on a SET with a BINARY OPERATOR. The only restriction on the operator is CLOSURE (i.e., applying the BINARY OPERATOR to two elements of a given set  $S$  returns a value which is itself a member of  $S$ ). Associativity, commutativity, etc., are not required (Rosenfeld 1968, pp. 88–103). A groupoid can be empty. The numbers of nonisomorphic groupoids of this type having  $n$  elements are 1, 1, 10, 3330, 178981952, ... (Sloane's A001329), and the numbers of nonisomorphic and nonantiisomorphic groupoids are 1, 7, 1734, 89521056, ... (Sloane's A001424). An associative groupoid is called a SEMI-GROUP.

The second type of groupoid is an algebraic structure first defined by Brandt (1926) and also known as a VIRTUAL GROUP. A groupoid with base  $B$  is a set  $G$  with mappings  $\alpha$  and  $\beta$  from  $G$  onto  $B$  and a partially defined binary operation  $(g, h) \mapsto gh$ , satisfying the following four conditions:

1.  $gh$  is defined only when  $\beta(G) = \alpha(h)$  for certain maps  $\alpha$  and  $\beta$  from  $G$  onto  $\mathbb{R}^2$  with  $\alpha : (x, \gamma, y) \mapsto x$  and  $\beta : (x, \gamma, y) \mapsto y$ .
2. ASSOCIATIVITY: If either  $(gh)k$  or  $g(hk)$  is defined, then so is the other and  $(gh)k = g(hk)$ .
3. For each  $g$  in  $G$ , there are left and right IDENTITY ELEMENTS  $\lambda_g$  and  $\rho_g$  such that  $\lambda_g g = g = g \rho_g$ .
4. Each  $g$  in  $G$  has an inverse  $g^{-1}$  for which  $gg^{-1} = \lambda_g$  and  $g^{-1}g = \rho_g$ .

(Weinstein 1996). A groupoid is a small CATEGORY with every morphism invertible.

## Growth Function

see BLOCK GROWTH

## Growth Spiral

see LOGARITHMIC SPIRAL

**Grundy's Game**

A special case of NIM played by the following rules. Given a heap of size  $n$ , two players alternately select a heap and divide it into two unequal heaps. A player loses when he cannot make a legal move because all heaps have size 1 or 2. Flammenkamp gives a table of the extremal SPRAGUE-GRUNDY VALUES for this game. The first few values of Grundy's game are 0, 0, 0, 1, 0, 2, 1, 0, 2, ... (Sloane's A002188).

**Gudermannian Function**

Denoted either  $\gamma(x)$  or  $\text{gd}(x)$ .

$$\text{gd}(x) \equiv \tan^{-1}(\sinh x) = 2 \tan^{-1}(e^x) - \frac{1}{2}\pi \quad (1)$$

$$\text{gd}^{-1}(x) = \ln[\tan(\frac{1}{4}\pi + \frac{1}{2}x)] = \ln(\sec x + \tan x). \quad (2)$$

The derivatives are given by

$$\frac{d}{dx} \text{gd}(x) = \text{sech } x \quad (3)$$

$$\frac{d}{dx} \text{gd}^{-1}(x) = \sec x. \quad (4)$$

**Guldinus Theorem**

see PAPPUS'S CENTROID THEOREM

**Gumbel's Distribution**

A special case of the FISHER-TIPPETT DISTRIBUTION with  $a = 0$ ,  $b = 1$ . The MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\begin{aligned} \mu &= \gamma \\ \sigma^2 &= \frac{1}{6}\pi^2 \\ \gamma_1 &= \frac{12\sqrt{6}\zeta(3)}{\pi^3} \\ \gamma_2 &= \frac{12}{5}. \end{aligned}$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT, and  $\zeta(3)$  is APÉRY'S CONSTANT.

see also FISHER-TIPPETT DISTRIBUTION

**Guthrie's Problem**

The problem of deciding if four-colors are sufficient to color any map on a plane or SPHERE.

see also FOUR-COLOR THEOREM

**Gutschoven's Curve**

see KAPPA CURVE

**Guy's Conjecture**

Guy's conjecture, which has not yet been proven or disproven, states that the CROSSING NUMBER for a COMPLETE GRAPH of order  $n$  is

$$\frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lfloor \frac{n-1}{2} \right\rfloor \left\lfloor \frac{n-2}{2} \right\rfloor \left\lfloor \frac{n-3}{2} \right\rfloor,$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, which can be rewritten

$$\begin{cases} \frac{1}{64}n(n-2)^2(n-4) & \text{for } n \text{ even} \\ \frac{1}{64}(n-1)^2(n-3)^2 & \text{for } n \text{ odd.} \end{cases}$$

The first few values are 0, 0, 0, 0, 1, 3, 9, 18, 36, 60, ... (Sloane's A000241).

**Gyroelongated Square Dipyramid**

One of the eight convex DELTAHEDRA. It consists of two oppositely faced SQUARE PYRAMIDS rotated  $45^\circ$  to each other and separated by a ribbon of eight side-to-side TRIANGLES. It is JOHNSON SOLID  $J_{17}$ .

Call the coordinates of the upper PYRAMID bases  $(\pm 1, \pm 1, h_1)$  and of the lower  $(\pm\sqrt{2}, 0, -h_1)$  and  $(0, \pm\sqrt{2}, -h_1)$ . Call the PYRAMID apexes  $(0, 0, \pm(h_1 + h_2))$ . Consider the points  $(1, 1, 0)$  and  $(0, 0, h_1 + h_2)$ . The height of the PYRAMID is then given by

$$\sqrt{1^2 + 1^2 + h_2^2} = \sqrt{2 + h_2^2} = 2 \quad (1)$$

$$h_2 = \sqrt{2}. \quad (2)$$

Now consider the points  $(1, 1, h_1)$  and  $(\sqrt{2}, 0, -h_1)$ . The height of the base is given by

$$(1 - \sqrt{2})^2 + 1^2 + (2h_1)^2 = 1 - 2\sqrt{2} + 2 + 1 + 4h_1^2 = 4 - 2\sqrt{2} + 4h_1^2 = 2^2 = 4 \quad (3)$$

$$4h_1^2 = 2\sqrt{2} \quad (4)$$

$$h_1^2 = \frac{\sqrt{2}}{2} = \frac{1}{\sqrt{2}} = 2^{-1/2}, \quad (5)$$

so

$$h_1 = 2^{-1/4} \quad (6)$$

$$h_2 = 2^{1/2}. \quad (7)$$

# H

## h-Cobordism

An *h*-cobordism is a COBORDISM  $W$  between two MANIFOLDS  $M_1$  and  $M_2$  such that  $W$  is SIMPLY CONNECTED and the inclusion maps  $M_1 \rightarrow W$  and  $M_2 \rightarrow W$  are HOMOTOPY equivalences.

## h-Cobordism Theorem

If  $W$  is a SIMPLY CONNECTED, COMPACT MANIFOLD with a boundary that has two components,  $M_1$  and  $M_2$ , such that inclusion of each is a HOMOTOPY equivalence, then  $W$  is DIFFEOMORPHIC to the product  $M_1 \times [0, 1]$  for  $\dim(M_1) \geq 5$ . In other words, if  $M$  and  $M'$  are two simply connected MANIFOLDS of DIMENSION  $\geq 5$  and there exists an *h*-COBORDISM  $W$  between them, then  $W$  is a product  $M \times I$  and  $M$  is DIFFEOMORPHIC to  $M'$ .

The proof of the *h*-cobordism theorem can be accomplished using SURGERY. A particular case of the *h*-cobordism theorem is the POINCARÉ CONJECTURE in dimension  $n \geq 5$ . Smale proved this theorem in 1961.

see also DIFFEOMORPHISM, POINCARÉ CONJECTURE, SURGERY

## H-Spread

The difference  $H_2 - H_1$ , where  $H_1$  and  $H_2$  are HINGES. It is the same as the INTERQUARTILE RANGE for  $N = 5, 9, 13, \dots$  points.

see also HINGE, INTERQUARTILE RANGE, STEP

## References

Tukey, J. W. *Explanatory Data Analysis*. Reading, MA: Addison-Wesley, p. 44, 1977.

## H-Transform

A 2-D generalization of the HAAR TRANSFORM which is used for the compression of astronomical images. The algorithm consists of dividing the  $2^N \times 2^N$  image into blocks of  $2 \times 2$  pixels, calling the pixels in the block  $a_{00}, a_{10}, a_{01}$ , and  $a_{11}$ . For each block, compute the four coefficients

$$h_0 \equiv \frac{1}{2}(a_{11} + a_{10} + a_{01} + a_{00})$$

$$h_x \equiv \frac{1}{2}(a_{11} + a_{10} - a_{01} - a_{00})$$

$$h_y \equiv \frac{1}{2}(a_{11} - a_{10} + a_{01} - a_{00})$$

$$h_c \equiv \frac{1}{2}(a_{11} - a_{10} - a_{01} + a_{00}).$$

Construct a  $2^{N-1} \times 2^{N-1}$  image from the  $h_0$  values, and repeat until only one  $h_0$  value remains. The H-transform can be performed in place and requires about  $16N^2/3$  additions for an  $N \times N$  image.

Stewart, I. *The Problems of Mathematics*, 2nd ed. Oxford, England: Oxford University Press, 1987.

A SYMMETRIC BLOCK DESIGN  $(4n+3, n+1, n)$  which is equivalent to a HADAMARD MATRIX of order  $4n+4$ . It is conjectured that Hadamard designs exist from all integers  $n > 0$ , but this has not yet been proven. This elusive proof (or disproof) remains one of the most important unsolved problems in COMBINATORICS.

Dinitz, J. H. and Stinson, D. R. "A Brief Introduction to Design Theory." Ch. 1 in *Contemporary Design Theory: A Collection of Surveys* (Ed. J. H. Dinitz and D. R. Stinson). New York: Wiley, pp. 1-12, 1992.

Let  $A = a_{ii}$  be an arbitrary  $n \times n$  nonsingular MATRIX with REAL elements and DETERMINANT  $|A|$ , then

$$|A|^2 \leq \prod_{i=1}^n \left( \sum_{k=1}^n a_{ik}^2 \right).$$

see also HADAMARD'S THEOREM

#### Hadamard Matrix

A class of SQUARE MATRIX invented by Sylvester (1867) under the name of ANALLAGMATIC PAVEMENT. A Hadamard matrix is a SQUARE MATRIX containing only 1s and -1s such that when any two columns or rows are placed side by side, HALF the adjacent cells are the same SIGN and half the other (excepting from the count an L-shaped "half-frame" bordering the matrix on two sides which is composed entirely of 1s). When viewed as pavements, cells with 1s are colored black and those with -1s are colored white. Therefore, the  $n \times n$  Hadamard matrix  $H_n$  must have  $n(n-1)/2$  white squares (-1s) and  $n(n+1)/2$  black squares (1s).

This is equivalent to the definition

$$H_n H_n^T = nI_n, \quad (1)$$

where  $I_n$  is the  $n \times n$  IDENTITY MATRIX. A Hadamard matrix of order  $4n+4$  corresponds to a HADAMARD DESIGN  $(4n+3, 2n+1, n)$ .

PALEY'S THEOREM guarantees that there always exists a Hadamard matrix  $H_n$  when  $n$  is divisible by 4 and of the form  $2^e(q^m+1)$ , where  $p$  is an ODD PRIME. In such cases, the MATRICES can be constructed using a PALEY CONSTRUCTION. The PALEY CLASS  $k$  is undefined for the following values of  $m < 1000$ : 92, 116, 156, 172, 184, 188, 232, 236, 260, 268, 292, 324, 356, 372, 376, 404, 412, 428, 436, 452, 472, 476, 508, 520, 532, 536, 584, 596, 604, 612, 652, 668, 712, 716, 732, 756, 764, 772, 808, 836, 852, 856, 872, 876, 892, 904, 932, 940, 944, 952, 956, 964, 980, 988, 996.

Sawade (1985) constructed  $H_{268}$ . It is conjectured (and verified up to  $n < 428$ ) that  $H_n$  exists for all  $n$  DIVISIBLE by 4 (van Lint and Wilson 1993). However, the proof of this CONJECTURE remains an important problem in CODING THEORY. The number of Hadamard matrices of order  $4n$  are 1, 1, 1, 5, 3, 60, 487, ... (Sloane's A007299).

If  $H_n$  and  $H_m$  are known, then  $H_{nm}$  can be obtained by replacing all 1s in  $H_m$  by  $H_n$  and all -1s by  $-H_n$ . For  $n \leq 100$ , Hadamard matrices with  $n = 12, 20, 28, 36,$

44, 52, 60, 68, 76, 84, 92, and 100 cannot be built up from lower order Hadamard matrices.

$$H_2 = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \quad (2)$$

$$H_4 = \begin{bmatrix} H_2 & H_2 \\ -H_2 & H_2 \end{bmatrix} = \begin{bmatrix} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} & \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \\ -\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} & \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \end{bmatrix}$$

$$= \begin{bmatrix} 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \end{bmatrix} \quad (3)$$

$H_8$  can be similarly generated from  $H_4$ . Hadamard matrices can also be expressed in terms of the WALSH FUNCTIONS Cal and Sal

$$H_8 = \begin{bmatrix} \text{Cal}(0, t) \\ \text{Sal}(4, t) \\ \text{Sal}(2, t) \\ \text{Cal}(2, t) \\ \text{Sal}(1, t) \\ \text{Cal}(3, t) \\ \text{Cal}(1, t) \\ \text{Sal}(3, t) \end{bmatrix} \quad (4)$$

Hadamard matrices can be used to make ERROR-CORRECTING CODES.

see also HADAMARD DESIGN, PALEY CONSTRUCTION, PALEY'S THEOREM, WALSH FUNCTION

### Hadamard Transform

A FAST FOURIER TRANSFORM-like ALGORITHM which produces a hologram of an image.

### Hadamard-Vallée Poussin Constants

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

The sum of RECIPROCALs of PRIMES diverges, but

$$\begin{aligned} \lim_{n \rightarrow \infty} \left[ \sum_{k=1}^{\pi(n)} \frac{1}{p_k} - \ln(\ln n) \right] \\ = \gamma + \sum_{k=1}^{\infty} \left[ \ln \left( 1 - \frac{1}{p_k} \right) + \frac{1}{p_k} \right] \\ \equiv C_1 = 0.2614972128 \dots, \quad (1) \end{aligned}$$

where  $\pi(n)$  is the PRIME COUNTING FUNCTION and  $\gamma$  is the EULER-MASCHERONI CONSTANT (Le Lionnais 1983). Hardy and Wright (1985) show that, if  $\omega(n)$  is the number of distinct PRIME factors of  $n$ , then

$$\lim_{n \rightarrow \infty} \left[ \frac{1}{n} \sum_{k=1}^n \omega(k) - \ln(\ln n) \right] = C_1. \quad (2)$$

Furthermore, if  $\Omega(n)$  is the total number of PRIME factors of  $n$ , then

$$\begin{aligned} \lim_{n \rightarrow \infty} \left[ \frac{1}{n} \sum_{k=1}^n \Omega(k) - \ln(\ln n) \right] \\ = C_1 + \sum_{k=1}^{\infty} \frac{1}{p_k(p_k - 1)} = 1.0346538819 \dots \quad (3) \end{aligned}$$

Similarly,

$$\begin{aligned} \lim_{n \rightarrow \infty} \left( \sum_{k=1}^{\pi(n)} \frac{\ln p_k}{p_k} - \ln n \right) = -\gamma - \sum_{j=2}^{\infty} \sum_{k=1}^{\infty} \frac{\ln p_k}{p_k^j} \\ \equiv -C_2 = -1.3325822757 \dots \quad (4) \end{aligned}$$

### Hadwiger's Principal Theorem

The VECTORS  $\pm \mathbf{a}_1, \dots, \pm \mathbf{a}_n$  in a 3-space form a normalized EUTACTIC STAR IFF  $T\mathbf{x} = \mathbf{x}$  for all  $\mathbf{x}$  in the 3-space.

### Hadwiger Problem

What is the largest number of subcubes (not necessarily different) into which a CUBE cannot be divided by plane cuts? The answer is 47.

see also CUBE DISSECTION

### Hafner-Sarnak-McCurley Constant

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Given two randomly chosen INTEGER  $n \times n$  matrices, what is the probability  $D(n)$  that the corresponding determinants are coprime? Hafner *et al.* (1993) showed that

$$D(n) = \prod_{p_k} \left\{ 1 - \left[ 1 - \prod_{j=1}^n (1 - p_k^{-j}) \right]^2 \right\}, \quad (1)$$

where the product is over PRIMES. The case  $D(1)$  is just the probability that two random INTEGERS are coprime,

$$D(1) = \frac{6}{\pi^2} = 0.6079271019 \dots \quad (2)$$

Vardi (1991) computed the limit

$$\sigma \equiv \lim_{n \rightarrow \infty} D(n) = 0.3532363719 \dots \quad (3)$$

The speed of convergence is roughly  $\sim 0.57^n$  (Flajolet and Vardi 1996).

### Hahn-Banach Theorem

A linear FUNCTIONAL defined on a SUBSPACE of a VECTOR SPACE  $V$  and which is dominated by a sublinear function defined on  $V$  has a linear extension which is also dominated by the sublinear function.

#### References

- Zeidler, E. *Applied Functional Analysis: Applications to Mathematical Physics*. New York: Springer-Verlag, 1995.

### Hailstone Number

Sequences of INTEGERS generated in the COLLATZ PROBLEM. For example, for a starting number of 7, the sequence is 7, 22, 11, 34, 17, 52, 26, 13, 40, 20, 10, 5, 16, 8, 4, 2, 1, 4, 2, 1, .... Such sequences are called hailstone sequences because the values typically rise and fall, somewhat analogously to a hailstone inside a cloud.

While a hailstone eventually becomes so heavy that it falls to ground, every starting INTEGER ever tested has produced a hailstone sequence that eventually drops down to the number 1 and then "bounces" into the small loop 4, 2, 1, ....

see also COLLATZ PROBLEM

### Hairy Ball Theorem

There does not exist an everywhere NONZERO VECTOR FIELD on the 2-SPHERE  $S^2$ . This implies that somewhere on the surface of the Earth, there is a point with zero horizontal wind velocity.

### Half

The UNIT FRACTION  $1/2$ .

see also QUARTER, SQUARE ROOT, UNIT FRACTION

### Half-Closed Interval

An INTERVAL in which one endpoint is included but not the other. A half-closed interval is denoted  $[a, b)$  or  $(a, b]$  and is also called a HALF-OPEN INTERVAL.

see also CLOSED INTERVAL, OPEN INTERVAL

### Half-Normal Distribution

A NORMAL DISTRIBUTION with MEAN 0 and STANDARD DEVIATION  $1/\theta$  limited to the domain  $[0, \infty)$ .

$$P(x) = \frac{2\theta}{\pi} e^{-x^2\theta^2/\pi} \quad (1)$$

$$D(x) = \operatorname{erf}\left(\frac{tx}{\sqrt{\pi}}\right). \quad (2)$$

The MOMENTS are

$$\mu_1 = \frac{1}{t} \quad (3)$$

$$\mu_2 = \frac{\pi}{2t^2} \quad (4)$$

$$\mu_3 = \frac{\pi}{t^3} \quad (5)$$

$$\mu_4 = \frac{3\pi^2}{4t^4}, \quad (6)$$

so the MEAN, VARIANCE, SKEWNESS, and KURTOSIS are

$$\mu = \frac{1}{\theta} \quad (7)$$

$$\sigma^2 \equiv \mu_2 - \mu_1^2 = \frac{\pi - 2}{2t^2} \quad (8)$$

$$\gamma_1 = 2\sqrt{\frac{2}{\pi}} \quad (9)$$

$$\gamma_2 = 0. \quad (10)$$

see also NORMAL DISTRIBUTION

### Half-Open Interval

see HALF-CLOSED INTERVAL

### Hall-Janko Group

The SPORADIC GROUP  $HJ$ , also denoted  $J_2$ .

see also JANKO GROUPS

**Halley's Irrational Formula**

A ROOT-finding ALGORITHM which makes use of a third-order TAYLOR SERIES

$$f(x) = f(x_n) + f'(x_n)(x - x_n) + \frac{1}{2}f''(x_n)(x - x_n)^2 + \dots \quad (1)$$

A ROOT of  $f(x)$  satisfies  $f(x) = 0$ , so

$$0 \approx f(x_n) + f'(x_n)(x_{n+1} - x_n) + \frac{1}{2}f''(x_n)(x_{n+1} - x_n)^2. \quad (2)$$

Using the QUADRATIC EQUATION then gives

$$x_{n+1} = x_n + \frac{-f'(x_n) \pm \sqrt{[f'(x_n)]^2 - 2f(x_n)f''(x_n)}}{f''(x_n)}. \quad (3)$$

Picking the plus sign gives the iteration function

$$C_f(x) = x - \frac{1 - \sqrt{1 - \frac{2f(x)f''(x)}{[f'(x)]^2}}}{\frac{f''(x)}{f'(x)}}. \quad (4)$$

This equation can be used as a starting point for deriving HALLEY'S METHOD.

If the alternate form of the QUADRATIC EQUATION is used instead in solving (2), the iteration function becomes instead

$$C_f(x) = x - \frac{2f(x)}{f'(x) \pm \sqrt{[f'(x)]^2 - 2f(x)f''(x)}}. \quad (5)$$

This form can also be derived by setting  $n = 2$  in LAGUERRE'S METHOD. Numerically, the SIGN in the DENOMINATOR is chosen to maximize its ABSOLUTE VALUE. Note that in the above equation, if  $f''(x) = 0$ , then NEWTON'S METHOD is recovered. This form of Halley's irrational formula has cubic convergence, and is usually found to be substantially more stable than NEWTON'S METHOD. However, it does run into difficulty when both  $f(x)$  and  $f'(x)$  or  $f'(x)$  and  $f''(x)$  are simultaneously near zero.

see also HALLEY'S METHOD, LAGUERRE'S METHOD, NEWTON'S METHOD

**References**

- Qiu, H. "A Robust Examination of the Newton-Raphson Method with Strong Global Convergence Properties." Master's Thesis. University of Central Florida, 1993.  
Scavo, T. R. and Thoo, J. B. "On the Geometry of Halley's Method." *Amer. Math. Monthly* **102**, 417-426, 1995.

**Halley's Method**

Also known as the TANGENT HYPERBOLAS METHOD or HALLEY'S RATIONAL FORMULA. As in HALLEY'S IRRATIONAL FORMULA, take the second-order TAYLOR POLYNOMIAL

$$f(x) = f(x_n) + f'(x_n)(x - x_n) + \frac{1}{2}f''(x_n)(x - x_n)^2 + \dots \quad (1)$$

A ROOT of  $f(x)$  satisfies  $f(x) = 0$ , so

$$0 \approx f(x_n) + f'(x_n)(x_{n+1} - x_n) + \frac{1}{2}f''(x_n)(x_{n+1} - x_n)^2. \quad (2)$$

Now write

$$0 = f(x_n) + (x_{n+1} - x_n)[f'(x_n) + \frac{1}{2}f''(x_n)(x_{n+1} - x_n)], \quad (3)$$

giving

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n) + \frac{1}{2}f''(x_n)(x_{n+1} - x_n)}. \quad (4)$$

Using the result from NEWTON'S METHOD,

$$x_{n+1} - x_n = -\frac{f(x_n)}{f'(x_n)}, \quad (5)$$

gives

$$x_{n+1} = x_n - \frac{2f(x_n)f'(x_n)}{2[f'(x_n)]^2 - f(x_n)f''(x_n)}, \quad (6)$$

so the iteration function is

$$H_f(x) = x - \frac{2f(x)f'(x)}{2[f'(x)]^2 - f(x)f''(x)}. \quad (7)$$

This satisfies  $H'_f(\alpha) = H''_f(\alpha) = 0$  where  $\alpha$  is a ROOT, so it is third order for simple zeros. Curiously, the third derivative

$$H'''_f(\alpha) = -\left\{ \frac{f'''(\alpha)}{f'(\alpha)} - \frac{3}{2} \left[ \frac{f''(\alpha)}{f'(\alpha)} \right]^2 \right\} \quad (8)$$

is the SCHWARZIAN DERIVATIVE. Halley's method may also be derived by applying NEWTON'S METHOD to  $ff'^{-1/2}$ . It may also be derived by using an OSCULATING CURVE of the form

$$y(x) = \frac{(x - x_n) + c}{a(x - x_n) + b}. \quad (9)$$

Taking derivatives,

$$f(x_n) = \frac{c}{b} \quad (10)$$

$$f'(x_n) = \frac{b - ac}{b^2} \quad (11)$$

$$f''(x_n) = \frac{2a(ac - b)}{b^3}, \quad (12)$$

which has solutions

$$a = -\frac{f''(x_n)}{2[f'(x_n)]^2 - f(x_n)f''(x_n)} \quad (13)$$

$$b = \frac{2f'(x_n)}{2[f'(x_n)]^2 - f(x_n)f''(x_n)} \quad (14)$$

$$c = \frac{2f(x_n)f'(x_n)}{2[f'(x_n)]^2 - f(x_n)f''(x_n)}, \quad (15)$$

so at a ROOT,  $y(x_{n+1}) = 0$  and

$$x_{n+1} = x_n - c, \quad (16)$$

which is Halley's method.

### Hamilton's Rules

The rules for the MULTIPLICATION of QUATERNIONS.

see also QUATERNION

### Hamiltonian Circuit

A closed loop through a GRAPH that visits each node exactly once and ends adjacent to the initial point. The Hamiltonian circuit is named after Sir William Rowan Hamilton, who devised a puzzle in which such a path along the EDGES of an ICOSAEDRON was sought (the ICOSIAN GAME).

All PLATONIC SOLIDS have a Hamiltonian circuit, as do planar 4-connected graphs. However, no foolproof method is known for determining whether a given general GRAPH has a Hamiltonian circuit. The number of Hamiltonian circuits on an  $n$ -HYPERCUBE is 2, 8, 96, 43008, ... (Sloane's A006069, Gardner 1986, pp. 23–24).

**Hamiltonian Group**

A non-Abelian GROUP all of whose SUBGROUPS are self-conjugate.

References

- Carmichael, R. D. "Hamiltonian Groups." §31 in *Introduction to the Theory of Groups of Finite Order*. New York: Dover, p. 113–116, 1956.

**Hamiltonian Map**

Consider a 1-D Hamiltonian MAP of the form

$$H(p, q) = \frac{1}{2}p^2 + V(q), \quad (1)$$

which satisfies HAMILTON'S EQUATIONS

$$\dot{q} = \frac{\partial H}{\partial p} \quad (2)$$

$$\dot{p} = -\frac{\partial H}{\partial q}. \quad (3)$$

Now, write

$$\dot{q}_i = \frac{(q_{i+1} - q_i)}{\Delta t}, \quad (4)$$

where

$$q_i = q(t) \quad (5)$$

$$q_{i+1} = q(t + \Delta t). \quad (6)$$

Then the equations of motion become

$$q_{i+1} = q_i + p_i \Delta t \quad (7)$$

$$p_{i+1} = p_i - \Delta t \left( \frac{\partial V}{\partial q_i} \right)_{q=q_i}. \quad (8)$$

Note that equations (7) and (8) are not AREA-PRESERVING, since

$$\frac{\partial(q_{i+1}, p_{i+1})}{\partial(q_i, p_i)} = \begin{vmatrix} 1 & -\Delta t \frac{\partial^2 V}{\partial q_i^2} \\ \Delta t & 1 \end{vmatrix} = 1 + (\Delta t)^2 \frac{\partial^2 V}{\partial q_i^2} \neq 1. \quad (9)$$

However, if we take instead of (7) and (8),

$$q_{i+1} = q_i + p_i \Delta t \quad (10)$$

$$p_{i+1} = p_i - \Delta t \left( \frac{\partial V}{\partial q_i} \right)_{q=q_{i+1}} \quad (11)$$

$$\begin{aligned} \frac{\partial(q_{i+1}, p_{i+1})}{\partial(q_i, p_i)} &= \begin{vmatrix} 1 & -\Delta t \frac{\partial}{\partial q_i} \left( \frac{\partial V}{\partial q} \right)_{q=q_{i+1}} \\ \Delta t & 1 \end{vmatrix} \\ &= 1 + (\Delta t)^2 \frac{\partial^2 V}{\partial q_i^2} = 1, \end{aligned} \quad (12)$$

which is AREA-PRESERVING.

**Hamiltonian Path**

A loop through a GRAPH that visits each node exactly once but does *not* end adjacent to the initial point. The number of Hamiltonian paths on an  $n$ -HYPERCUBE is 0, 0, 48, 48384, ... (Sloane's A006070, Gardner 1986, pp. 23–24).

see also HAMILTONIAN CIRCUIT, HAMILTONIAN GRAPH

References

- Gardner, M. "The Binary Gray Code." In *Knotted Doughnuts and Other Mathematical Entertainments*. New York: W. H. Freeman, pp. 23–24, 1986.  
 Sloane, N. J. A. Sequence A006070/M5295 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Hamiltonian System**

A system of variables which can be written in the form of HAMILTON'S EQUATIONS.

**Hammer-Aitoff Equal-Area Projection**

A MAP PROJECTION whose inverse is defined using the intermediate variable

$$z \equiv \sqrt{1 - \left(\frac{1}{4}x\right)^2 - \left(\frac{1}{2}y\right)^2}.$$

Then the longitude and latitude are given by

$$\lambda = 2 \tan^{-1} \left( \frac{zx}{2(2z^2 - 1)} \right)$$

$$\phi = \sin^{-1}(yz).$$

**Hamming Function**

An APODIZATION FUNCTION chosen to minimize the height of the highest sidelobe. The Hamming function is given by

$$A(x) = 0.54 + 0.46 \cos \left( \frac{\pi x}{a} \right), \quad (1)$$

Its FULL WIDTH AT HALF MAXIMUM is  $1.05543a$ . The corresponding INSTRUMENT FUNCTION is

$$I(k) = \frac{a(1.08 - 0.64a^2k^2) \operatorname{sinc}(2\pi ak)}{1 - 4a^2k^2}. \quad (2)$$

This APODIZATION FUNCTION is close to the one produced by the requirement that the APPARATUS FUNCTION goes to 0 at  $ka = 5/4$ . From APODIZATION FUNCTION, a general symmetric apodization function  $A(x)$  can be written as a FOURIER SERIES

$$A(x) = a_0 + 2 \sum_{n=1}^{\infty} a_n \cos\left(\frac{n\pi x}{b}\right), \quad (3)$$

where the COEFFICIENTS satisfy

$$a_0 + 2 \sum_{n=1}^{\infty} a_n = 1. \quad (4)$$

The corresponding apparatus function is

$$I(t) = 2b\{a_0 \operatorname{sinc}(2\pi kb) + \sum_{n=1}^{\infty} [\operatorname{sinc}(2\pi kb + n\pi) + \operatorname{sinc}(2\pi kb - n\pi)]\}. \quad (5)$$

To obtain an APODIZATION FUNCTION with zero at  $ka = 3/4$ , use

$$a_0 + 2a_1 = 1, \quad (6)$$

so

$$a_0 \operatorname{sinc}\left(\frac{5}{2}\pi\right) + a_1 [\operatorname{sinc}\left(\frac{7}{2}\pi\right) + \operatorname{sinc}\left(\frac{3}{2}\pi\right)] = 0 \quad (7)$$

$$(1-2a_1) \frac{2}{5\pi} - a_1 \left( \frac{2}{7\pi} + \frac{2}{3\pi} \right) = (1-2a_1) \frac{1}{5} - a_1 \left( \frac{1}{7} + \frac{1}{3} \right) = 0 \quad (8)$$

$$a_1 \left( \frac{1}{7} + \frac{1}{3} + \frac{2}{5} \right) = \frac{1}{5} \quad (9)$$

$$a_1 = \frac{\frac{1}{5}}{\frac{2}{5} + \frac{1}{7} + \frac{1}{3}} = \frac{7 \cdot 3}{2 \cdot 3 \cdot 7 + 3 \cdot 5 + 5 \cdot 7} = \frac{21}{92} \approx 0.2283 \quad (10)$$

$$a_0 = 1 - 2a_1 = \frac{92 - 2 \cdot 21}{92} = \frac{92 - 42}{92} = \frac{50}{92} = \frac{25}{46} \approx 0.5435. \quad (11)$$

The FWHM is 1.81522, the peak is 1.08, the peak NEGATIVE and POSITIVE sidelobes (in units of the peak) are -0.00689132 and 0.00734934, respectively.

#### Handedness

Objects which are identical except for a mirror reflection are said to display handedness and to be CHIRAL.

see also AMPHICHIRAL, CHIRAL, ENANTIOMER, MIRROR IMAGE

#### Handkerchief Surface

A surface given by the parametric equations

$$\begin{aligned} x(u, v) &= u \\ y(u, v) &= v \\ z(u, v) &= \frac{1}{3}u^3 + uv^2 + 2(u^2 - v^2). \end{aligned}$$

#### References

Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, p. 628, 1993.

#### Handle

Handles are to MANIFOLDS as CELLS are to CW-COMPLEXES. If  $M$  is a MANIFOLD together with a  $(k-1)$ -SPHERE  $S^{k-1}$  embedded in its boundary with a trivial TUBULAR NEIGHBORHOOD, we attach a  $k$ -handle to  $M$  by gluing the tubular NEIGHBORHOOD of the  $(k-1)$ -SPHERE  $S^{k-1}$  to the TUBULAR NEIGHBORHOOD of the standard  $(k-1)$ -SPHERE  $S^{k-1}$  in the  $\dim(M)$ -dimensional DISK.

In this way, attaching a  $k$ -handle is essentially just the process of attaching a fattened-up  $k$ -DISK to  $M$  along the  $(k-1)$ -SPHERE  $S^{k-1}$ . The embedded DISK in this new MANIFOLD is called the  $k$ -handle in the UNION of  $M$  and the handle.

see also HANDLEBODY, SURGERY, TUBULAR NEIGHBORHOOD

#### Handlebody

A handlebody of type  $(n, k)$  is an  $n$ -D MANIFOLD that is attained from the standard  $n$ -DISK by attaching only  $k$ -D HANDLES.

**Hankel Function of the First Kind**

$$H_n^{(1)}(z) \equiv J_n(z) + iY_n(z),$$

where  $J_n(z)$  is a BESSEL FUNCTION OF THE FIRST KIND and  $Y_n(z)$  is a BESSEL FUNCTION OF THE SECOND KIND. Hankel functions of the first kind can be represented as a CONTOUR INTEGRAL using

$$H_n^{(1)}(z) = \frac{1}{i\pi} \int_0^\infty \int_{\text{upper half plane}} \frac{e^{(z/2)(t-1/t)}}{t^{n+1}} dt.$$

see also DEBYE'S ASYMPTOTIC REPRESENTATION, WATSON-NICHOLSON FORMULA, WEYRICH'S FORMULA

**References**

Arfken, G. "Hankel Functions." §11.4 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 604–610, 1985.

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 623–624, 1953.

**Hankel Function of the Second Kind**

$$H_n^{(2)}(z) \equiv J_n(z) - iY_n(z),$$

where  $J_n(z)$  is a BESSEL FUNCTION OF THE FIRST KIND and  $Y_n(z)$  is a BESSEL FUNCTION OF THE SECOND KIND. Hankel functions of the second kind can be represented as a CONTOUR INTEGRAL using

$$H_n^{(2)}(z) = \frac{1}{i\pi} \int_{-\infty}^0 \int_{\text{lower half plane}} \frac{e^{(z/2)(t-1/t)}}{t^{n+1}} dt.$$

see also WATSON-NICHOLSON FORMULA

**References**

Arfken, G. "Hankel Functions." §11.4 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 604–610, 1985.

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 623–624, 1953.

**Hankel's Integral**

$$J_m(x) = \frac{x^m}{2^{m-1}\sqrt{\pi}\Gamma\left(m + \frac{1}{2}\right)} \times \int_0^1 \cos(xt)(1-t^2)^{m-1/2} dt,$$

where  $J_m(x)$  is a BESSEL FUNCTION OF THE FIRST KIND and  $\Gamma(z)$  is the GAMMA FUNCTION. Hankel's integral can be derived from SONINE'S INTEGRAL.

see also POISSON INTEGRAL, SONINE'S INTEGRAL

**Hankel Matrix**

A MATRIX with identical values for each element in a given diagonal. Define  $H_n$  to be the Hankel matrix with leading column made up of the INTEGERS  $1, \dots, n$ , then

$$H_2 = \begin{bmatrix} 1 & 2 \\ 2 & 0 \end{bmatrix}$$

$$H_3 = \begin{bmatrix} 1 & 2 & 3 \\ 2 & 3 & 0 \\ 3 & 0 & 0 \end{bmatrix}.$$

**Hankel Transform**

Equivalent to a 2-D FOURIER TRANSFORM with a radially symmetric KERNEL, and also called the FOURIER-BESSEL TRANSFORM.

$$g(u, v) = \mathcal{F}[f(r)] = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(r) e^{-2\pi i(ux+vy)} dx dy. \quad (1)$$

Let

$$x + iy = r e^{i\theta} \quad (2)$$

$$u + iv = q e^{i\phi} \quad (3)$$

so that

$$x = r \cos \theta \quad (4)$$

$$y = r \sin \theta \quad (5)$$

$$r = \sqrt{x^2 + y^2} \quad (6)$$

$$u = q \cos \phi \quad (7)$$

$$v = q \sin \phi \quad (8)$$

$$q = \sqrt{u^2 + v^2}. \quad (9)$$

Then

$$\begin{aligned} g(q) &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi i r q (\cos \phi \cos \theta + \sin \phi \sin \theta)} r dr d\theta \\ &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi i r q \cos(\theta - \phi)} r dr d\theta \\ &= \int_0^\infty \int_{-\phi}^{2\pi - \phi} f(r) e^{-2\pi i r q \cos \theta} r dr d\theta \\ &= \int_0^\infty \int_0^{2\pi} f(r) e^{-2\pi i r q \cos \theta} r dr d\theta \\ &= \int_0^\infty f(r) \left[ \int_0^{2\pi} e^{-2\pi i r q \cos \theta} d\theta \right] r dr \\ &= 2\pi \int_0^\infty f(r) J_0(2\pi q r) r dr, \end{aligned} \quad (10)$$

where  $J_0(z)$  is a zeroth order BESSEL FUNCTION OF THE FIRST KIND. Therefore, the Hankel transform pairs are

$$g(k) = \int_0^\infty f(x) J_0(kx) x dx \quad (11)$$

$$f(x) = \int_0^\infty g(k) J_0(kx) k dk. \quad (12)$$

see also BESSEL FUNCTION OF THE FIRST KIND, FOURIER TRANSFORM, LAPLACE TRANSFORM

#### References

### Hann Function

see HANNING FUNCTION

### Hanning Function

An APODIZATION FUNCTION, also called the HANN FUNCTION, frequently used to reduce ALIASING in FOURIER TRANSFORMS. The illustrations above show the Hanning function, its INSTRUMENT FUNCTION, and a blowup of the INSTRUMENT FUNCTION sidelobes. The Hanning function is given by

$$f(x) = \cos^2\left(\frac{\pi x}{2a}\right) = \frac{1}{2} - \frac{1}{2} \cos\left(\frac{\pi x}{a}\right). \quad (1)$$

The INSTRUMENT FUNCTION for Hanning apodization can also be written

$$a[\text{sinc}(2\pi ka) + \frac{1}{2} \text{sinc}(2\pi ka - \pi) + \frac{1}{2} \text{sinc}(2\pi ka + \pi)]. \quad (2)$$

Its FULL WIDTH AT HALF MAXIMUM is  $a$ . It has APPARATUS FUNCTION

$$\begin{aligned} A(x) &= \int_{-a}^a \left[ \frac{1}{2} - \frac{1}{2} \cos\left(\frac{\pi x}{a}\right) \right] e^{-2\pi i k x} dx \\ &= \frac{1}{2} \int_{-a}^a e^{-2\pi i k x} dx - \frac{1}{2} \int_{-a}^a e^{-2\pi i k x} \cos\left(\frac{\pi x}{a}\right) dx \\ &\equiv \frac{1}{2}(A_1 + A_2). \end{aligned} \quad (3)$$

The first integral is

$$I_1 = \int_{-a}^a e^{-2\pi i k x} dx = \frac{\sin(2\pi ka)}{\pi k} = 2a \text{sinc}(2\pi ka). \quad (4)$$

The second integral can be rewritten

$$\begin{aligned} I_2 &= \int_{-a}^0 \cos\left(\frac{\pi x}{a}\right) e^{-2\pi i k x} dx \\ &\quad + \int_0^a \cos\left(\frac{\pi x}{a}\right) e^{-2\pi i k x} dx \\ &= \int_0^a \cos\left(\frac{\pi x}{a}\right) (e^{2\pi i k x} + e^{-2\pi i k x}) dx \\ &= 2 \int_0^a \cos\left(\frac{\pi x}{a}\right) \cos(2\pi k x) dx \\ &= 2 \left\{ \frac{\sin\left(\frac{\pi}{a} - 2\pi k\right) x}{2\left(\frac{\pi}{a} - 2\pi k\right)} + \frac{\sin\left(\frac{\pi}{a} + 2\pi k\right) x}{2\left(\frac{\pi}{a} + 2\pi k\right)} \right\}_0^a \\ &= a \left[ \frac{\sin(\pi - 2\pi ka)}{\pi - 2\pi ka} + \frac{\sin(\pi + 2\pi ka)}{\pi + 2\pi ka} \right] \\ &= \frac{a}{\pi} \left[ \frac{\sin(2\pi ka)}{1 - 2ka} - \frac{\sin(2\pi ka)}{1 + 2ka} \right] \\ &= a[\text{sinc}(\pi - 2\pi ka) + \text{sinc}(\pi + 2\pi ka)]. \end{aligned} \quad (5)$$

Combining (4) and (5) gives

$$A(x) = a[\text{sinc}(2\pi ka) + \frac{1}{2} \text{sinc}(\pi - 2\pi ka) + \frac{1}{2} \text{sinc}(\pi + 2\pi ka)]. \quad (6)$$

To find the extrema, define  $x \equiv 2\pi ka$  and rewrite (6) as

$$A(x) = a[\sin x + \frac{1}{2} \text{sinc}(x - \pi) + \frac{1}{2} \text{sinc}(x + \pi)]. \quad (7)$$

Then solve

$$\frac{dA}{dx} = \frac{\pi^2(-x^3 \cos x + 3x^2 \sin x + \pi^2 x \cos x - \pi^2 \sin x)}{x^2(\pi^2 - x^2)^2} = 0 \quad (8)$$

to find the extrema. The roots are  $x = 7.42023$  and  $10.7061$ , giving a peak NEGATIVE sidelobe of  $-0.026708$  and a peak POSITIVE sidelobe (in units of  $a$ ) of  $0.00843441$ . The peak in units of  $a$  is 1, and the full-width at half maximum is given by setting (7) equal to  $1/2$  and solving for  $x$ , yielding

$$x_{1/2} = 2\pi k_{1/2} a = \pi. \quad (9)$$

Therefore, with  $L \equiv 2a$ , the FULL WIDTH AT HALF MAXIMUM is

$$\text{FWHM} = 2k_{1/2} = \frac{1}{a} = \frac{2}{L}. \quad (10)$$

see also APODIZATION FUNCTION, HAMMING FUNCTION

**Hanoi Graph**

A GRAPH  $H_n$  arising in conjunction with the TOWERS OF HANOI problem. The above figure is the Hanoi graph  $H_3$ .

see also TOWERS OF HANOI

**Hansen Number**

A number  $n$  for which a shortest chain exists which is a HANSEN CHAIN is called a Hansen number.

**References**

Guy, R. K. *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 111–112, 1994.

**Hansen's Problem**

A SURVEYING PROBLEM: from the position of two known but inaccessible points  $A$  and  $B$ , determine the position of two unknown accessible points  $P$  and  $P'$  by bearings from  $A, B, P'$  to  $P$  and  $A, B, P$  to  $P'$ .

see also SURVEYING PROBLEMS

**References**

Dörrie, H. "Annex to a Survey." §40 in *100 Great Problems of Elementary Mathematics: Their History and Solutions*. New York: Dover, pp. 193–197, 1965.

**Happy Number**

Let the sum of the SQUARES of the DIGITS of a POSITIVE INTEGER  $s_0$  be represented by  $s_1$ . In a similar way, let the sum of the SQUARES of the DIGITS of  $s_1$  be represented by  $s_2$ , and so on. If some  $s_i = 1$  for  $i \geq 1$ , then the original INTEGER  $s_0$  is said to be happy.

Once it is known whether a number is happy (or not), then any number in the sequence  $s_1, s_2, s_3, \dots$  will also be happy (or not). A number which is not happy is called UNHAPPY. Unhappy numbers have EVENTUALLY PERIODIC sequences of  $s_i$ : 4, 16, 37, 58, 89, 145, 42, 20, 4, ... which do not reach 1.

Any PERMUTATION of the DIGITS of an UNHAPPY or happy number must also be unhappy or happy. This follows from the fact that ADDITION is COMMUTATIVE. The first few happy numbers are 1, 7, 10, 13, 19, 23, 28, 31, 32, 44, 49, 68, 70, 79, 82, 86, 91, 94, 97, 100, ... (Sloane's A007770). These are also the numbers whose 2-RECURRING DIGITAL INVARIANT sequences have period 1.

**Hard Hexagon Entropy Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

A constant related to the HARD SQUARE ENTROPY CONSTANT. This constant is given by

$$\kappa_h \equiv \lim_{N \rightarrow \infty} [G(N)]^{1/N} = 1.395485972\dots, \quad (1)$$

where  $G(N)$  is the number of configurations of nonattacking KINGS on an  $n \times n$  chessboard with regular hexagonal cells, where  $N \equiv n^2$ . Amazingly,  $\kappa_h$  is algebraic and given by

$$\kappa_h \equiv \kappa_1 \kappa_2 \kappa_3 \kappa_4, \quad (2)$$

where

$$\kappa_1 \equiv 4^{-1} 3^{5/4} 11^{-5/12} c^{-2} \quad (3)$$

$$\kappa_2 \equiv [1 - \sqrt{1-c} + \sqrt{2+c+2\sqrt{1+c+c^2}}]^2 \quad (4)$$

$$\kappa_3 \equiv [-1 - \sqrt{1-c} + \sqrt{2+c+2\sqrt{1+c+c^2}}]^2 \quad (5)$$

$$\kappa_4 \equiv [\sqrt{1-a} + \sqrt{2+a+2\sqrt{1+a+a^2}}]^{-1/2} \quad (6)$$

$$a \equiv -\frac{124}{363} 11^{1/3} \quad (7)$$

$$b \equiv \frac{2501}{11979} 33^{1/2} \quad (8)$$

$$c \equiv \{\frac{1}{4} + \frac{3}{8} a[(b+1)^{1/3} - (b-1)^{1/3}]\}^{1/3}. \quad (9)$$

(Baxter 1980, Joyce 1988).

**Hard Square Entropy Constant**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Let  $F(n^2)$  be the number of binary  $n \times n$  MATRICES with no adjacent 1s (in either columns or rows). Define  $N \equiv n^2$ , then the hard square entropy constant is defined by

$$\kappa \equiv \lim_{N \rightarrow \infty} [F(N)]^{1/N} = 1.503048082\dots$$

The quantity  $\ln \kappa$  arises in statistical physics (Baxter *et al.* 1980, Pearce and Seaton 1988), and is known as the entropy per site of hard squares. A related constant known as the HARD HEXAGON ENTROPY CONSTANT can also be defined.

**Hardy's Inequality**

Let  $\{a_n\}$  be a NONNEGATIVE SEQUENCE and  $f(x)$  a NONNEGATIVE integrable FUNCTION. Define

$$A_n = \sum_{k=1}^n a_k \quad (1)$$

$$B_n = \sum_{k=n}^{\infty} a_k \quad (2)$$

and

$$F(x) = \int_0^x f(t) dt \quad (3)$$

$$G(x) = \int_x^{\infty} f(t) dt, \quad (4)$$

and take  $p > 1$ . For sums,

$$\sum_{n=1}^{\infty} \left( \frac{A_n}{n} \right)^p < \left( \frac{p}{p-1} \right)^p \sum_{n=1}^{\infty} (a_n)^p \quad (5)$$

(unless all  $a_n = 0$ ), and for integrals,

$$\int_0^{\infty} \left[ \frac{F(x)}{x} \right]^p dx < \left( \frac{p}{p-1} \right)^p \int_0^{\infty} [f(x)]^p dx \quad (6)$$

(unless  $f$  is identically 0).

**Hardy-Littlewood Conjectures**

The first Hardy-Littlewood conjecture is called the  $k$ -TUPLE CONJECTURE. It states that the asymptotic number of PRIME CONSTELLATIONS can be computed explicitly.

The second Hardy-Littlewood conjecture states that

$$\pi(x+y) - \pi(x) \leq \pi(y)$$

for all  $x$  and  $y$ , where  $\pi(x)$  is the PRIME COUNTING FUNCTION. Although it is not obvious, Richards (1974) proved that this conjecture is incompatible with the first Hardy-Littlewood conjecture.

see also PRIME CONSTELLATION, PRIME COUNTING FUNCTION

**Hardy-Ramanujan Number**

The smallest nontrivial TAXICAB NUMBER, i.e., the smallest number representable in two ways as a sum of two CUBES. It is given by

$$1729 = 1^3 + 12^3 = 9^3 + 10^3.$$

The number derives its name from the following story G. H. Hardy told about Ramanujan. “Once, in the taxi from London, Hardy noticed its number, 1729. He must have thought about it a little because he entered the room where Ramanujan lay in bed and, with scarcely a hello, blurted out his disappointment with it. It was, he declared, ‘rather a dull number,’ adding that he hoped that wasn’t a bad omen. ‘No, Hardy,’ said Ramanujan, ‘it is a very interesting number. It is the smallest number expressible as the sum of two [POSITIVE] cubes in two different ways’” (Hofstadter 1989, Kanigel 1991, Snow 1993).

see also DIOPHANTINE EQUATION—CUBIC, TAXICAB NUMBER

**References**

**Hardy-Ramanujan Theorem**

Let  $\omega(n)$  be the number of DISTINCT PRIME FACTORS of  $n$ . If  $\Psi(x)$  tends steadily to infinity with  $x$ , then

$$\ln \ln x - \Psi(x) \sqrt{\ln \ln x} < \omega(n) < \ln \ln x + \Psi(x) \sqrt{\ln \ln x}$$

for ALMOST ALL numbers  $n < x$ . “ALMOST ALL” means here the frequency of those INTEGERS  $n$  in the interval  $1 \leq n \leq x$  for which

$$|\omega(n) - \ln \ln x| > \Psi(x) \sqrt{\ln \ln x}$$

approaches 0 as  $x \rightarrow \infty$ .

see also DISTINCT PRIME FACTORS, ERDŐS-KAC THEOREM

**Hardy’s Rule**

Let the values of a function  $f(x)$  be tabulated at intervals equally spaced by  $h$  about  $x_0$ , so that  $f_{-3} = f(x_0 - 3h)$ ,  $f_{-2} = f(x_0 - 2h)$ , etc. Then Hardy’s rule gives the approximation to the integral of  $f(x)$  as

$$\int_{x_0-3h}^{x_0+3h} f(x) dx = \frac{1}{100} h (28f_{-3} + 162f_{-2} + 22f_0 + 162f_2 + 28f_3) + \frac{9}{1400} h^7 [2f^{(4)}(\xi_2) - h^2 f^{(8)}(\xi_1)],$$

where the final term gives the error, with  $\xi_1, \xi_2 \in [x_0 - 3h, x_0 + 3h]$ .

see also BODE’S RULE, DURAND’S RULE, NEWTON-COTES FORMULAS, SIMPSON’S 3/8 RULE, SIMPSON’S RULE, TRAPEZOIDAL RULE, WEDDLE’S RULE

**Harmonic Addition Theorem**

To convert an equation of the form

$$f(\theta) = a \cos \theta + b \sin \theta \quad (1)$$

to the form

$$f(\theta) = c \cos(\theta + \delta), \quad (2)$$

expand (2) using the trigonometric addition formulas to obtain

$$f(\theta) = c \cos \theta \cos \delta - c \sin \theta \sin \delta. \quad (3)$$

Now equate the COEFFICIENTS of (1) and (3)

$$a = c \cos \delta \quad (4)$$

$$b = -c \sin \delta, \quad (5)$$

so

$$\tan \delta = -\frac{b}{a} \quad (6)$$

$$a^2 + b^2 = c^2, \quad (7)$$

and we have

$$\delta = \tan^{-1} \left( -\frac{b}{a} \right) \quad (8)$$

$$c = \sqrt{a^2 + b^2}. \quad (9)$$

Given two general sinusoidal functions with frequency  $\omega$ :

$$\psi_1 = A_1 \sin(\omega t + \delta_1) \quad (10)$$

$$\psi_2 = A_2 \sin(\omega t + \delta_2), \quad (11)$$

their sum  $\psi$  can be expressed as a sinusoidal function with frequency  $\omega$

$$\begin{aligned} \psi &\equiv \psi_1 + \psi_2 = A_1[\sin(\omega t) \cos \delta_1 + \sin \delta_1 \cos(\omega t)] \\ &\quad + A_2[\sin(\omega t) \cos \delta_2 + \sin \delta_2 \cos(\omega t)] \\ &= [A_1 \cos \delta_1 + A_2 \cos \delta_2] \sin(\omega t) \\ &\quad + [A_1 \sin \delta_1 + A_2 \sin \delta_2] \cos(\omega t). \end{aligned} \quad (12)$$

Now, define

$$A \cos \delta \equiv A_1 \cos \delta_1 + A_2 \cos \delta_2 \quad (13)$$

$$A \sin \delta \equiv A_1 \sin \delta_1 + A_2 \sin \delta_2. \quad (14)$$

Then (12) becomes

$$A \cos \delta \sin(\omega t) + A \sin \delta \cos(\omega t) = A \sin(\omega t + \delta). \quad (15)$$

Square and add (13) and (14)

$$A_2 = A_1^2 + A_2^2 + 2A_1A_2 \cos(\delta_2 - \delta_1). \quad (16)$$

Also, divide (14) by (13)

$$\tan \delta = \frac{A_1 \sin \delta_1 + A_2 \sin \delta_2}{A_1 \cos \delta_1 + A_2 \cos \delta_2}, \quad (17)$$

so

$$\psi = A \sin(\omega t + \delta), \quad (18)$$

where  $A$  and  $\delta$  are defined by (16) and (17).

This procedure can be generalized to a sum of  $n$  harmonic waves, giving

$$\psi = \sum_{i=1}^n A_i \cos(\omega t + \delta_i) = A \cos(\omega t + \delta), \quad (19)$$

where

$$A^2 \equiv \sum_{i=1}^n A_i^2 + 2 \sum_{j>i} \sum_{i=1}^n A_i A_j \cos(\delta_i - \delta_j) \quad (20)$$

and

$$\tan \delta = -\frac{\sum_{i=1}^n A_i \sin \delta_i}{\sum_{i=1}^n A_i \cos \delta_i}. \quad (21)$$

## Harmonic Analysis

see also FOURIER SERIES

## Harmonic Brick

A right-angled PARALLELEPIPED with dimensions  $a \times ab \times abc$ , where  $a$ ,  $b$ , and  $c$  are INTEGERS.

see also BRICK, DE BRUIJN'S THEOREM, EULER BRICK

## Harmonic Conjugate Function

The harmonic conjugate to a given function  $u(x, y)$  is a function  $v(x, y)$  such that

$$f(x, y) = u(x, y) + v(x, y)$$

is COMPLEX DIFFERENTIABLE (i.e., satisfies the CAUCHY-RIEMANN EQUATIONS). It is given by

$$v(z) = \int u x dy - u y dx.$$

## Harmonic Conjugate Points

Given COLLINEAR points  $W$ ,  $X$ ,  $Y$ , and  $Z$ ,  $Y$  and  $Z$  are harmonic conjugates with respect to  $W$  and  $X$  if

$$\frac{|WY|}{|YX|} = \frac{|WZ|}{|ZX|}.$$

The distances between such points are said to be in HARMONIC RATIO, and the LINE SEGMENT depicted above is called a HARMONIC SEGMENT.

Harmonic conjugate points are also defined for a TRIANGLE. If  $W$  and  $X$  have TRILINEAR COORDINATES  $\alpha : \beta : \gamma$  and  $\alpha' : \beta' : \gamma'$ , then the TRILINEAR COORDINATES of the harmonic conjugates are

$$\begin{aligned} Y &= \alpha + \alpha' : \beta + \beta' : \gamma + \gamma' \\ Z &= \alpha - \alpha' : \beta - \beta' : \gamma - \gamma' \end{aligned}$$

(Kimberling 1994).

## Harmonic Coordinates

Satisfy the condition

$$\Gamma^\lambda \equiv g^{\mu\nu} \Gamma_{\mu\nu}^\lambda = 0, \quad (1)$$

or equivalently,

$$\frac{\partial}{\partial x^\kappa} (\sqrt{g} g^{\lambda\kappa}) = 0. \quad (2)$$

It is always possible to choose such a system. Using the D'ALEMBERTIAN OPERATOR,

$$\square^2 \phi \equiv (g^{\lambda\kappa} \phi_{,\lambda})_{,\kappa} = g^{\lambda\kappa} \frac{\partial^2 \phi}{\partial x^\lambda \partial x^\kappa} - \Gamma^\lambda \frac{\partial \phi}{\partial x^\lambda}. \quad (3)$$

But since  $\Gamma^\lambda \equiv 0$  for harmonic coordinates,

$$\square^2 x^\mu = 0. \quad (4)$$

### Harmonic Decomposition

A POLYNOMIAL function in the elements of  $\mathbf{x}$  can be uniquely decomposed into a sum of harmonic POLYNOMIALS times POWERS of  $|\mathbf{x}|$ .

### Harmonic Divisor Number

A number  $n$  for which the HARMONIC MEAN of the DIVISORS of  $n$ , i.e.,  $nd(n)/\sigma(n)$ , is an INTEGER, where  $d(n)$  is the number of POSITIVE integral DIVISORS of  $n$  and  $\sigma(n)$  is the DIVISOR FUNCTION. For example, the divisors of  $n = 140$  are 1, 2, 4, 5, 7, 10, 14, 20, 28, 35, 70, and 140, giving

$$\begin{aligned} d(140) &= 12 \\ \sigma(140) &= 336 \\ \frac{140d(140)}{\sigma(140)} &= \frac{140 \cdot 12}{336} = 5, \end{aligned}$$

so 140 is a harmonic divisor number. Harmonic divisor numbers are also called ORE NUMBERS. Garcia (1954) gives the 45 harmonic divisor numbers less than  $10^7$ . The first few are 1, 6, 140, 270, 672, 1638, ... (Sloane's A007340).

For distinct PRIMES  $p$  and  $q$ , harmonic divisor numbers are equivalent to EVEN PERFECT NUMBERS for numbers of the form  $p^r q$ . Mills (1972) proved that if there exists an ODD POSITIVE harmonic divisor number  $n$ , then  $n$  has a prime-POWER factor greater than  $10^7$ .

Another type of number called "harmonic" is the HARMONIC NUMBER.

see also DIVISOR FUNCTION, HARMONIC NUMBER

### Harmonic Equation

see LAPLACE'S EQUATION

### Harmonic Function

Any real-valued function  $u(x, y)$  with continuous second PARTIAL DERIVATIVES which satisfies LAPLACE'S EQUATION

$$\nabla^2 u(x, y) = 0 \quad (1)$$

is called a harmonic function. Harmonic functions are called POTENTIAL FUNCTIONS in physics and engineering. Potential functions are extremely useful, for example, in electromagnetism, where they reduce the study of a 3-component VECTOR FIELD to a 1-component SCALAR FUNCTION. A scalar harmonic function is called a SCALAR POTENTIAL, and a vector harmonic function is called a VECTOR POTENTIAL.

To find a class of such functions in the PLANE, write the LAPLACE'S EQUATION in POLAR COORDINATES

$$u_{rr} + \frac{1}{r} u_r + \frac{1}{r^2} u_{\theta\theta} = 0, \quad (2)$$

and consider only radial solutions

$$u_{rr} + \frac{1}{r} u_r = 0. \quad (3)$$

This is integrable by quadrature, so define  $v \equiv du/dr$ ,

$$\frac{dv}{dr} + \frac{1}{r} v = 0 \quad (4)$$

$$\frac{dv}{v} = -\frac{dr}{r} \quad (5)$$

$$\ln \left( \frac{v}{A} \right) = -\ln r \quad (6)$$

$$\frac{v}{A} = \frac{1}{r} \quad (7)$$

$$v = \frac{du}{dr} = \frac{A}{r} \quad (8)$$

$$du = A \frac{dr}{r}, \quad (9)$$

so the solution is

$$u = A \ln r. \quad (10)$$

Ignoring the trivial additive and multiplicative constants, the general pure radial solution then becomes

$$u = \ln[(x-a)^2 + (y-b)^2]^{1/2} = \frac{1}{2} \ln [(x-a)^2 + (y-b)^2]. \quad (11)$$

Other solutions may be obtained by differentiation, such as

$$u = \frac{x - a}{(x - a)^2 + (y - b)^2} \quad (12)$$

$$v = \frac{y - b}{(x - a)^2 + (y - b)^2}, \quad (13)$$

$$u = e^x \sin y \quad (14)$$

$$v = e^x \cos y, \quad (15)$$

and

$$\tan^{-1} \left( \frac{y - b}{x - a} \right). \quad (16)$$

Harmonic functions containing azimuthal dependence include

$$u = r^n \cos(n\theta) \quad (17)$$

$$v = r^n \sin(n\theta). \quad (18)$$

The POISSON KERNEL

$$u(r, R, \theta, \phi) = \frac{R^2 - r^2}{R^2 - 2rR \cos(\theta - \phi) + r^2} \quad (19)$$

is another harmonic function.

#### Harmonic-Geometric Mean

Let

$$\alpha_{n+1} = \frac{2\alpha_n\beta_n}{\alpha_n + \beta_n}$$

$$\beta_{n+1} = \sqrt{\alpha_n\beta_n},$$

then

$$H(\alpha_0, \beta_0) \equiv \lim_{n \rightarrow \infty} a_n = \frac{1}{M(\alpha_0^{-1}, \beta_0^{-1})},$$

where  $M$  is the ARITHMETIC-GEOMETRIC MEAN.

see also ARITHMETIC MEAN, ARITHMETIC-GEOMETRIC MEAN, GEOMETRIC MEAN, HARMONIC MEAN

#### Harmonic Homology

A PERSPECTIVE COLLINEATION with center  $O$  and axis  $o$  not incident is called a HOMOLOGY. A HOMOLOGY is said to be harmonic if the points  $A$  and  $A'$  on a line through  $O$  are harmonic conjugates with respect to  $O$  and  $o \cdot a$ . Every PERSPECTIVE COLLINEATION of period two is a harmonic homology.

see also HOMOLOGY (GEOMETRY), PERSPECTIVE COLLINEATION

#### Harmonic Logarithm

For all INTEGERS  $n$  and NONNEGATIVE INTEGERS  $t$ , the harmonic logarithms  $\lambda_n^{(t)}(x)$  of order  $t$  and degree  $n$  are defined as the unique functions satisfying

1.  $\lambda_0^{(t)}(x) = (\ln x)^t$ ,
2.  $\lambda_n^{(t)}(x)$  has no constant term except  $\lambda_0^{(0)}(x) = 1$ ,
3.  $\frac{d}{dx} \lambda_n^{(t)}(x) = [n] \lambda_{n-1}^{(t)}(x)$ ,

where the "ROMAN SYMBOL"  $[n]$  is defined by

$$[n] \equiv \begin{cases} n & \text{for } n \neq 0 \\ 1 & \text{for } n = 0 \end{cases} \quad (1)$$

(Roman 1992). This gives the special cases

$$\lambda_n^{(0)}(x) = \begin{cases} x^n & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \quad (2)$$

$$\lambda_n^{(1)}(x) = \begin{cases} x^n (\ln x - H_n) & \text{for } n \geq 0 \\ x^n & \text{for } n < 0, \end{cases} \quad (3)$$

where  $H_n$  is a HARMONIC NUMBER

$$H_n \equiv \sum_{k=1}^n \frac{1}{k}. \quad (4)$$

The harmonic logarithm has the INTEGRAL

$$\int \lambda_n^{(1)}(x) dx = \frac{1}{[n+1]} \lambda_{n+1}^{(1)}(x). \quad (5)$$

The harmonic logarithm can be written

$$\lambda_n^{(t)}(x) = [n]! \tilde{D}^{-n} (\ln x)^t, \quad (6)$$

where  $\tilde{D}$  is the DIFFERENTIAL OPERATOR, (so  $\tilde{D}^{-n}$  is the  $n$ th INTEGRAL). Rearranging gives

$$\tilde{D}^k \lambda_n^{(t)}(x) = \left[ \frac{[n]!}{[n-k]} \right]! \lambda_{n-k}^{(t)}(x). \quad (7)$$

This formulation gives an analog of the BINOMIAL THEOREM called the LOGARITHMIC BINOMIAL FORMULA. Another expression for the harmonic logarithm is

$$\lambda_n^{(t)}(x) = x^n \sum_{j=0}^t (-1)^j (t)_j c_n^{(j)} (\ln x)^{t-j}, \quad (8)$$

where  $(t)_j = t(t-1)\cdots(t-j+1)$  is a POCHHAMMER SYMBOL and  $c_n^{(j)}$  is a two-index HARMONIC NUMBER (Roman 1992).

 Eels, J. and Lemaire, L. "Another Report on Harmonic Maps." *Bull. London Math. Soc.* **20**, 385–524, 1988.

### Harmonic Mean

The harmonic mean  $H(x_1, \dots, x_n)$  of  $n$  points  $x_i$  (where  $i = 1, \dots, n$ ) is

$$\frac{1}{H} \equiv \frac{1}{n} \sum_{i=1}^n \frac{1}{x_i}. \quad (1)$$

The special case of  $n = 2$  is therefore

$$\frac{1}{H} = \frac{1}{2} \left( \frac{1}{x_1} + \frac{1}{x_2} \right) \quad (2)$$

or

$$\frac{1}{H} = \frac{x_1 + x_2}{2x_1x_2}. \quad (3)$$

The VOLUME-to-SURFACE AREA ratio for a cylindrical container with height  $h$  and radius  $r$  and the MEAN CURVATURE of a general surface are related to the harmonic mean.

Hoehn and Niven (1985) show that

$$H(a_1 + c, a_2 + c, \dots, a_n + c) > c + H(a_1, a_2, \dots, a_n) \quad (4)$$

for any POSITIVE constant  $c$ .

### Harmonic Number

A number of the form

$$H_n = \sum_{k=1}^n \frac{1}{k}. \quad (1)$$

This can be expressed analytically as

$$H_n = \gamma + \psi_0(n+1), \quad (2)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\Psi(x) = \psi_0(x)$  is the DIGAMMA FUNCTION. The number formed by taking alternate signs in the sum also has an analytic solution

$$H'_n = \sum_{k=1}^n \frac{(-1)^{k+1}}{k} = \ln 2 + \frac{1}{2}(-1)^n [\psi_0(\frac{1}{2}n + \frac{1}{2}) - \psi_0(\frac{1}{2}n + 1)]. \quad (3)$$

The first few harmonic numbers  $H_n$  are 1, 3/2, 11/6, 25/12, 137/60, ... (Sloane's A001008 and A002805). The HARMONIC NUMBER  $H_n$  is never an INTEGER (except for  $H_1$ ), which can be proved by using the strong triangle inequality to show that the 2-ADIC VALUE of  $H_n$  is greater than 1 for  $n > 1$ . The harmonic numbers have ODD NUMERATORS and EVEN DENOMINATORS. The  $n$ th harmonic number is given asymptotically by

$$H_n \sim \ln n + \gamma + \frac{1}{2n}, \quad (5)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT (Conway and Guy 1996). Gosper gave the interesting identity

$$\sum_{i=0}^{\infty} \frac{z^i H_i}{i!} = -e^z \sum_{k=1}^{\infty} \frac{(-z)^k}{kk!} = e^z [\ln z + \Gamma(0, z) + \gamma], \quad (6)$$

where  $\Gamma(0, z)$  is the incomplete GAMMA FUNCTION and  $\gamma$  is the EULER-MASCHERONI CONSTANT. Borwein and Borwein (1995) show that

$$\sum_{n=1}^{\infty} \frac{H_n^2}{(n+1)^2} = \frac{11}{4} \zeta(4) = \frac{11}{360} \pi^4 \quad (7)$$

$$\sum_{n=1}^{\infty} \frac{H_n^2}{n^2} = \frac{17}{4} \zeta(4) = \frac{17}{360} \pi^4 \quad (8)$$

$$\sum_{n=1}^{\infty} \frac{H_n}{n^3} = \frac{5}{4} \zeta(4) = \frac{1}{72} \pi^4, \quad (9)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION. The first of these had been previously derived by de Doelder (1991), and the last by Euler (1775). These identities are corollaries of the identity

$$\frac{1}{\pi} \int_0^{\pi} x^2 \{\ln[2 \cos(\frac{1}{2}x)]\}^2 dx = \frac{11}{2} \zeta(4) = \frac{11}{180} \pi^4 \quad (10)$$

(Borwein and Borwein 1995). Additional identities due to Euler are

$$\sum_{n=1}^{\infty} \frac{H_n}{n^2} = 2\zeta(3) \quad (11)$$

$$2 \sum_{n=1}^{\infty} \frac{H_n}{n^m} = (m+2)\zeta(m+1) - \sum_{n=1}^{m-2} \zeta(m-n)\zeta(n+1) \quad (12)$$

for  $m = 2, 3, \dots$  (Borwein and Borwein 1995), where  $\zeta(3)$  is APÉRY'S CONSTANT. These sums are related to so-called EULER SUMS.

Conway and Guy (1996) define the second harmonic number by

$$H_n^{(2)} \equiv \sum_{i=1}^n H_i = (n+1)(H_{n+1}-1) = (n+1)(H_{n+1}-H_1), \quad (13)$$

the third harmonic number by

$$H_n^{(3)} \equiv \sum_{i=1}^n H_i^{(2)} = \binom{n+2}{2} (H_{n+2} - H_2), \quad (14)$$

and the  $n$ th harmonic number by

$$H_n^{(k)} = \binom{n+k-1}{k-1} (H_{n+k-1} - H_{k-1}). \quad (15)$$

A slightly different definition of a two-index harmonic number  $c_n^{(j)}$  is given by Roman (1992) in connection with the HARMONIC LOGARITHM. Roman (1992) defines this by

$$c_n^{(0)} = \begin{cases} 1 & \text{for } n \geq 0 \\ 0 & \text{for } n < 0 \end{cases} \quad (16)$$

$$c_0^{(j)} = \begin{cases} 1 & \text{for } j = 0 \\ 0 & \text{for } j \neq 0 \end{cases} \quad (17)$$

plus the recurrence relation

$$cn_n^{(j)} = c_n^{(j-1)} + nc_{n-1}^{(j)}. \quad (18)$$

For general  $n > 0$  and  $j > 0$ , this is equivalent to

$$c_n^{(j)} = \sum_{i=1}^n \frac{1}{i} c_i^{(j-1)}, \quad (19)$$

and for  $n > 0$ , it simplifies to

$$c_n^{(j)} = \sum_{i=1}^n \binom{n}{i} (-1)^{i-1} i^{-j}. \quad (20)$$

For  $n < 0$ , the harmonic number can be written

$$c_n^{(j)} = (-1)^j [n]! s(-n, j), \quad (21)$$

where  $[n]!$  is the ROMAN FACTORIAL and  $s$  is a STIRLING NUMBER OF THE FIRST KIND.

A separate type of number sometimes also called a "harmonic number" is a HARMONIC DIVISOR NUMBER (or ORE NUMBER).

**Harmonic Ratio**

see HARMONIC CONJUGATE POINTS

**Harmonic Segment**

see HARMONIC CONJUGATE POINTS

**Harmonic Series**

The SUM

$$\sum_{k=1}^{\infty} \frac{1}{k} \quad (1)$$

is called the harmonic series. It can be shown to DIVERGE using the INTEGRAL TEST by comparison with the function  $1/x$ . The divergence, however, is very slow. In fact, the sum

$$\sum_p \frac{1}{p} \quad (2)$$

taken over all PRIMES also diverges. The generalization of the harmonic series

$$\zeta(n) \equiv \sum_{k=1}^{\infty} \frac{1}{k^n} \quad (3)$$

is known as the RIEMANN ZETA FUNCTION.

The sum of the first few terms of the harmonic series is given analytically by the  $n$ th HARMONIC NUMBER

$$H_n = \sum_{j=1}^n \frac{1}{j} = \gamma + \psi_0(n+1), \quad (4)$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\Psi(x) = \psi_0(x)$  is the DIGAMMA FUNCTION. The number of terms needed to exceed 1, 2, 3, ... are 1, 4, 11, 31, 83, 227, 616, 1674, 4550, 12367, 33617, 91380, 248397, ... (Sloane's A004080). Using the analytic form shows that after  $2.5 \times 10^8$  terms, the sum is still less than 20. Furthermore, to achieve a sum greater than 100, more than  $1.509 \times 10^{43}$  terms are needed!

Progressions of the form

$$\frac{1}{a_1}, \frac{1}{a_1 + d}, \frac{1}{a_1 + 2d}, \dots \quad (5)$$

are also sometimes called harmonic series (Beyer 1987).

The modified harmonic series, given by the sum

$$T = \sum_{k=1}^{\infty} \frac{1}{p_k}, \quad (6)$$

where  $p_k$  is the  $k$ th PRIME, diverges.

### Harnack's Theorems

Harnack's first theorem states that a real irreducible curve of order  $n$  cannot have more than

$$\frac{1}{2}(n-1)(n-2) - \sum s_i(s_i-1) + 1$$

circuits (Coolidge 1959, p. 57).

Harnack's second theorem states that there exists a curve of every order with the maximum number of circuits compatible with that order and with a certain number of double points, provided that number is not permissible for a curve of lower order (Coolidge 1959, p. 61).

### Harshad Number

A POSITIVE INTEGER which is DIVISIBLE by the sum of its DIGITS, also called a NIVEN NUMBER (Kennedy *et al.* 1980). The first few are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 18, 20, 21, 24, ... (Sloane's A005349). Grundman (1994) proved that there is no sequence of more than 20 consecutive Harshad numbers, and found the smallest sequence of 20 consecutive Harshad numbers, each member of which has 44,363,342,786 digits.

Grundman (1994) defined an  $n$ -Harshad (or  $n$ -Niven) number to be a POSITIVE INTEGER which is DIVISIBLE by the sum of its digits in base  $n \geq 2$ . Cai (1996) showed that for  $n = 2$  or 3, there exists an infinite family of sequences of consecutive  $n$ -Harshad numbers of length  $2n$ .

### Hart's Inversor

A linkage which draws the inverse of a given curve. It can also convert circular to linear motion. The rods satisfy  $AB = CD$  and  $BC = DA$ , and  $O$ ,  $P$ , and  $P'$

remain COLLINEAR. Coxeter (1969, p. 428) shows that if  $AO = \mu AB$ , then

$$OP \times OP' = \mu(1 - \mu)(AD^2 - AB^2).$$

see also PEAUCELLIER INVERTOR

### Hartley Transform

AN INTEGRAL TRANSFORM which shares some features with the FOURIER TRANSFORM, but which (in the discrete case), multiplies the KERNEL by

$$\cos\left(\frac{2\pi kn}{N}\right) - \sin\left(\frac{2\pi kn}{N}\right) \quad (1)$$

instead of

$$e^{-2\pi i kn/N} = \cos\left(\frac{2\pi kn}{N}\right) - i \sin\left(\frac{2\pi kn}{N}\right). \quad (2)$$

The Hartley transform produces REAL output for a REAL input, and is its own inverse. It therefore can have computational advantages over the DISCRETE FOURIER TRANSFORM, although analytic expressions are usually more complicated for the Hartley transform.

The discrete version of the Hartley transform can be written explicitly as

$$\mathcal{H}[a] \equiv \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} a_n \left[ \cos\left(\frac{2\pi kn}{N}\right) - \sin\left(\frac{2\pi kn}{N}\right) \right] \quad (3)$$

$$= \Re \mathcal{F}[a] - \Im \mathcal{F}[a], \quad (4)$$

where  $\mathcal{F}$  denotes the FOURIER TRANSFORM. The Hartley transform obeys the CONVOLUTION property

$$\mathcal{H}[a * b]_k = \frac{1}{2}(A_k B_k - \bar{A}_k \bar{B}_k + A_k \bar{B}_k + \bar{A}_k B_k), \quad (5)$$

where

$$\bar{a}_0 \equiv a_0 \quad (6)$$

$$\bar{a}_{n/2} \equiv a_{n/2} \quad (7)$$

$$\bar{a}_k \equiv a_{n-k} \quad (8)$$

(Arndt). Like the FAST FOURIER TRANSFORM, there is a “fast” version of the Hartley transform. A decimation in time algorithm makes use of

$$\mathcal{H}_n^{\text{left}}[a] = \mathcal{H}_{n/2}[a^{\text{even}}] + \mathcal{X}\mathcal{H}_{n/2}[a^{\text{odd}}] \quad (9)$$

$$\mathcal{H}_n^{\text{right}}[a] = \mathcal{H}_{n/2}[a^{\text{even}}] - \mathcal{X}\mathcal{H}_{n/2}[a^{\text{odd}}], \quad (10)$$

where  $\mathcal{X}$  denotes the sequence with elements

$$a_n \cos\left(\frac{\pi n}{N}\right) - \bar{a}_n \sin\left(\frac{\pi n}{N}\right). \quad (11)$$

A decimation in frequency algorithm makes use of

$$\mathcal{H}_n^{\text{even}}[a] = \mathcal{H}_{n/2}[a^{\text{left}} + a^{\text{right}}], \quad (12)$$

$$\mathcal{H}_n^{\text{odd}}[a] = \mathcal{H}_{n/2}[\mathcal{X}(a^{\text{left}} - a^{\text{right}})]. \quad (13)$$

The DISCRETE FOURIER TRANSFORM

$$A_k \equiv \mathcal{F}[a] = \sum_{n=0}^{N-1} e^{-2\pi i k n / N} a_n \quad (14)$$

can be written

$$\begin{aligned} \begin{bmatrix} A_k \\ A_{-k} \end{bmatrix} &= \sum_{n=0}^{N-1} \underbrace{\begin{bmatrix} e^{-2\pi i k n / N} & 0 \\ 0 & e^{2\pi i k n / N} \end{bmatrix}}_{\mathbf{F}} \begin{bmatrix} a_n \\ a_n \end{bmatrix} \quad (15) \\ &= \sum_{n=0}^{N-1} \underbrace{\frac{1}{2} \begin{bmatrix} 1-i & 1+i \\ 1+i & 1-i \end{bmatrix}}_{\mathbf{T}^{-1}} \underbrace{\begin{bmatrix} \cos\left(\frac{2\pi k n}{N}\right) & \sin\left(\frac{2\pi k n}{N}\right) \\ -\sin\left(\frac{2\pi k n}{N}\right) & \cos\left(\frac{2\pi k n}{N}\right) \end{bmatrix}}_{\mathbf{H}} \\ &\quad \times \underbrace{\frac{1}{2} \begin{bmatrix} 1+i & 1-i \\ 1-i & 1+i \end{bmatrix}}_{\mathbf{T}} \begin{bmatrix} a_n \\ a_n \end{bmatrix}, \quad (16) \end{aligned}$$

so

$$\mathbf{F} = \mathbf{T}^{-1} \mathbf{H} \mathbf{T}. \quad (17)$$

#### Hasse-Davenport Relation

Let  $F$  be a FINITE FIELD with  $q$  elements, and let  $F_s$  be a FIELD containing  $F$  such that  $[F_s : F] = s$ . Let  $\chi$  be a nontrivial MULTIPLICATIVE CHARACTER of  $F$  and  $\chi' = \chi \circ N_{F_s/F}$  a character of  $F_s$ . Then

$$(-g(\chi))^s = -g(\chi'),$$

where  $g(x)$  is a GAUSSIAN SUM.

see also GAUSSIAN SUM, MULTIPLICATIVE CHARACTER

#### References

- Ireland, K. and Rosen, M. “A Proof of the Hasse-Davenport Relation.” §11.4 in *A Classical Introduction to Modern Number Theory*, 2nd ed. New York: Springer-Verlag, pp. 162–165, 1990.

#### Hasse Diagram

A graphical rendering of a PARTIALLY ORDERED SET displayed via the COVER relation of the PARTIALLY ORDERED SET with an implied upward orientation. A point is drawn for each element of the POSET, and line segments are drawn between these points according to the following two rules:

1. If  $x < y$  in the poset, then the point corresponding to  $x$  appears lower in the drawing than the point corresponding to  $y$ .
2. The line segment between the points corresponding to any two elements  $x$  and  $y$  of the poset is included in the drawing IFF  $x$  covers  $y$  or  $y$  covers  $x$ .

Hasse diagrams are also called UPWARD DRAWINGS.

### Hasse-Minkowski Theorem

Two nonsingular forms are equivalent over the rationals IFF they have the same DETERMINANT and the same  $p$ -SIGNATURES for all  $p$ .

### Hasse Principle

A collection of equations satisfies the Hasse principle if, whenever one of the equations has solutions in  $\mathbb{R}$  and all the  $\mathbb{Q}_p$ , then the equations have solutions in the RATIONALS  $\mathbb{Q}$ . Examples include the set of equations

$$ax^2 + bxy + cy^2 = 0$$

with  $a$ ,  $b$ , and  $c$  INTEGERS, and the set of equations

$$x^2 + y^2 = a$$

for  $a$  rational. The trivial solution  $x = y = 0$  is usually not taken into account when deciding if a collection of homogeneous equations satisfies the Hasse principle. The Hasse principle is sometimes called the LOCAL-GLOBAL PRINCIPLE.

see also LOCAL FIELD

### Hasse's Resolution Modulus Theorem

The JACOBI SYMBOL  $(a/y) = \chi(y)$  as a CHARACTER can be extended to the KRONECKER SYMBOL  $(f(a)/y) = \chi^*(y)$  so that  $\chi^*(y) = \chi(y)$  whenever  $\chi(y) \neq 0$ . When  $y$  is RELATIVELY PRIME to  $f(a)$ , then  $\chi^*(y) \neq 0$ , and for NONZERO values  $\chi^*(y_1) = \chi^*(y_2)$  IFF  $y_1 \equiv y_2 \pmod{f(a)}$ . In addition,  $|f(a)|$  is the minimum value for which the latter congruence property holds in any extension symbol for  $\chi(y)$ .

see also CHARACTER (NUMBER THEORY), JACOBI SYMBOL, KRONECKER SYMBOL

### References

Cohn, H. *Advanced Number Theory*. New York: Dover, pp. 35–36, 1980.

### Hat

The hat is a caret-shaped symbol most commonly used to denote a UNIT VECTOR ( $\hat{v}$ ) or an ESTIMATOR ( $\hat{x}$ ).

see also ESTIMATOR, UNIT VECTOR

### Haupt-Exponent

The smallest exponent  $e$  for which  $b^e \equiv 1 \pmod{p}$ , where  $b$  and  $p$  are given numbers, is the haupt-exponent of  $b \pmod{p}$ . The number of bases having a haupt-exponent  $e$  is  $\phi(e)$ , where  $\phi(e)$  is the TOTIENT FUNCTION. Cunningham (1922) published the haupt-exponents for primes to 25409 and bases 2, 3, 5, 6, 7, 10, 11, and 12.

see also COMPLETE RESIDUE SYSTEM, RESIDUE INDEX

### References

Cunningham, A. *Haupt-Exponents, Residue Indices, Primitive Roots*. London: F. Hodgson, 1922.

### Hausdorff Axioms

Describe subsets of elements  $x$  in a NEIGHBORHOOD SET  $E$  of  $x$ . The NEIGHBORHOOD is assumed to satisfy:

1. There corresponds to each point  $x$  at least one NEIGHBORHOOD  $U(x)$ , and each NEIGHBORHOOD  $U(x)$  contains the point  $x$ .
2. If  $U(x)$  and  $V(x)$  are two NEIGHBORHOODS of the same point  $x$ , there must exist a NEIGHBORHOOD  $W(x)$  that is a subset of both.
3. If the point  $y$  lies in  $U(x)$ , there must exist a NEIGHBORHOOD  $U(y)$  that is a SUBSET of  $U(x)$ .
4. For two different points  $x$  and  $y$ , there are two corresponding NEIGHBORHOODS  $U(x)$  and  $U(y)$  with no points in common.

### Hausdorff-Besicovitch Dimension

see CAPACITY DIMENSION

### Hausdorff Dimension

Let  $A$  be a SUBSET of a METRIC SPACE  $X$ . Then the Hausdorff dimension  $D(A)$  of  $A$  is the INFIMUM of  $d \geq 0$  such that the  $d$ -dimensional HAUSDORFF MEASURE of  $A$  is 0. Note that this need not be an INTEGER.

In many cases, the Hausdorff dimension correctly describes the correction term for a resonator with FRACTAL PERIMETER in Lorentz's conjecture. However, in general, the proper dimension to use turns out to be the MINKOWSKI-BOULIGAND DIMENSION (Schroeder 1991).

see also CAPACITY DIMENSION, FRACTAL DIMENSION, MINKOWSKI-BOULIGAND DIMENSION

### Hausdorff Measure

Let  $X$  be a METRIC SPACE,  $A$  be a SUBSET of  $X$ , and  $d$  a number  $\geq 0$ . The  $d$ -dimensional Hausdorff measure of  $A$ ,  $H^d(A)$ , is the INFIMUM of POSITIVE numbers  $y$  such that for every  $r > 0$ ,  $A$  can be covered by a countable family of closed sets, each of diameter less than  $r$ , such that the sum of the  $d$ th POWERS of their diameters is less than  $y$ . Note that  $H^d(A)$  may be infinite, and  $d$  need not be an INTEGER.

**Heads Minus Tails Distribution**

A fair COIN is tossed  $2n$  times. Let  $D \equiv |H - T|$  be the absolute difference in the number of heads and tails obtained. Then the probability distribution is given by

$$P(D = 2k) = \begin{cases} \left(\frac{1}{2}\right)^{2n} \binom{2n}{n} & k = 0 \\ 2\left(\frac{1}{2}\right)^{2n} \binom{2n}{n+k} & k = 1, 2, \dots, \end{cases}$$

where  $P(D = 2k - 1) = 0$ . The most probable value of  $D$  is  $D = 2$ , and the expectation value is

$$\langle D \rangle = \frac{n \binom{2n}{n}}{2^{2n-1}}.$$

**Heat Conduction Equation**

A diffusion equation of the form

$$\frac{\partial T}{\partial t} = \kappa \nabla^2 T. \quad (1)$$

Physically, the equation commonly arises in situations where  $\kappa$  is the thermal diffusivity and  $T$  the temperature.

The 1-D heat conduction equation is

$$\frac{\partial T}{\partial t} = \kappa \frac{\partial^2 T}{\partial x^2}. \quad (2)$$

This can be solved by SEPARATION OF VARIABLES using

$$T(x, t) = X(x)T(t). \quad (3)$$

Then

$$X \frac{dT}{dt} = \kappa T \frac{d^2 X}{dx^2}. \quad (4)$$

Dividing both sides by  $\kappa XT$  gives

$$\frac{1}{\kappa T} \frac{dT}{dt} = \frac{1}{X} \frac{d^2 X}{dx^2} = -\frac{1}{\lambda^2}, \quad (5)$$

where each side must be equal to a constant. Anticipating the exponential solution in  $T$ , we have picked a negative separation constant so that the solution remains finite at all times and  $\lambda$  has units of length. The  $T$  solution is

$$T(t) = Ae^{-\kappa t/\lambda^2}, \quad (6)$$

and the  $X$  solution is

$$X(x) = C \cos\left(\frac{x}{\lambda}\right) + D \sin\left(\frac{x}{\lambda}\right). \quad (7)$$

The general solution is then

$$\begin{aligned} T(x, t) &= T(t)X(x) \\ &= Ae^{-\kappa t/\lambda^2} \left[ C \cos\left(\frac{x}{\lambda}\right) + D \sin\left(\frac{x}{\lambda}\right) \right] \\ &= e^{-\kappa t/\lambda^2} \left[ D \cos\left(\frac{x}{\lambda}\right) + E \sin\left(\frac{x}{\lambda}\right) \right]. \end{aligned} \quad (8)$$

If we are given the boundary conditions

$$T(0, t) = 0 \quad (9)$$

and

$$T(L, t) = 0, \quad (10)$$

then applying (9) to (8) gives

$$D \cos\left(\frac{x}{\lambda}\right) = 0 \Rightarrow D = 0, \quad (11)$$

and applying (10) to (8) gives

$$E \sin\left(\frac{L}{\lambda}\right) = 0 \Rightarrow \frac{L}{\lambda} = n\pi \Rightarrow \lambda = \frac{L}{n\pi}, \quad (12)$$

so (8) becomes

$$T_n(x, t) = E_n e^{-\kappa(n\pi/L)^2 t} \sin\left(\frac{n\pi x}{L}\right). \quad (13)$$

Since the general solution can have any  $n$ ,

$$T(x, t) = \sum_{n=1}^{\infty} c_n \sin\left(\frac{n\pi x}{L}\right) e^{-\kappa(n\pi/L)^2 t}. \quad (14)$$

Now, if we are given an initial condition  $T(x, 0)$ , we have

$$T(x, 0) = \sum_{n=1}^{\infty} c_n \sin\left(\frac{n\pi x}{L}\right). \quad (15)$$

Multiplying both sides by  $\sin(m\pi x/L)$  and integrating from 0 to  $L$  gives

$$\begin{aligned} \int_0^L \sin\left(\frac{m\pi x}{L}\right) T(x, 0) dx \\ = \int_0^L \sum_{n=1}^{\infty} c_n \sin\left(\frac{m\pi x}{L}\right) \sin\left(\frac{n\pi x}{L}\right) dx. \end{aligned} \quad (16)$$

Using the ORTHOGONALITY of  $\sin(nx)$  and  $\sin(mx)$ ,

$$\begin{aligned} \sum_{n=1}^{\infty} c_n \int_0^L \sin\left(\frac{n\pi x}{L}\right) \sin\left(\frac{m\pi x}{L}\right) dx &= \sum_{n=1}^{\infty} \frac{1}{2} \pi \delta_{mn} c_n \\ &= \frac{1}{2} \pi c_m = \int_0^L \sin\left(\frac{m\pi x}{L}\right) T(x, 0) dx, \end{aligned} \quad (17)$$

so

$$c_n = \frac{2}{\pi} \int_0^L \sin\left(\frac{n\pi x}{L}\right) T(x, 0) dx. \quad (18)$$

If the boundary conditions are replaced by the requirement that the derivative of the temperature be zero at the edges, then (9) and (10) are replaced by

$$\left. \frac{\partial T}{\partial x} \right|_{(0,t)} = 0 \quad (19)$$

$$\left. \frac{\partial T}{\partial x} \right|_{(L,t)} = 0. \quad (20)$$

Following the same procedure as before, a similar answer is found, but with sine replaced by cosine:

$$T(x, t) = \sum_{n=1}^{\infty} c_n \cos\left(\frac{n\pi x}{L}\right) e^{-\kappa(n\pi/L)^2 t}, \quad (21)$$

where

$$c_n = \frac{2}{\pi} \int_0^L \cos\left(\frac{n\pi x}{L}\right) \left. \frac{\partial T(x, 0)}{\partial x} \right|_{t=0} dx. \quad (22)$$

### Heat Conduction Equation—Disk

To solve the HEAT CONDUCTION EQUATION on a 2-D disk of radius  $R = 1$ , try to separate the equation using

$$T(r, \theta, t) = R(r)\Theta(\theta)T(t). \quad (1)$$

Writing the  $\theta$  and  $r$  terms of the LAPLACIAN in SPHERICAL COORDINATES gives

$$\nabla^2 = \frac{d^2 R}{dr^2} + \frac{2}{r} \frac{dR}{dr} + \frac{1}{r^2} \frac{d^2 \Theta}{d\theta^2}, \quad (2)$$

so the HEAT CONDUCTION EQUATION becomes

$$\frac{R\Theta}{\kappa} \frac{d^2 T}{dt^2} = \frac{d^2 R}{dr^2} \Theta T + \frac{2}{r} \frac{dR}{dr} \Theta T + \frac{1}{r^2} \frac{d^2 \Theta}{d\theta^2} R T. \quad (3)$$

Multiplying through by  $r^2/R\Theta T$  gives

$$\frac{r^2}{\kappa T} \frac{d^2 T}{dt^2} = \frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} + \frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta}. \quad (4)$$

The  $\theta$  term can be separated.

$$\frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta} = -n(n+1), \quad (5)$$

which has a solution

$$\Theta(\theta) = A \cos \left[ \sqrt{n(n+1)} \theta \right] + B \sin \left[ \sqrt{n(n+1)} \theta \right]. \quad (6)$$

The remaining portion becomes

$$\frac{r^2}{\kappa T} \frac{d^2 T}{dt^2} = \frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} - n(n+1). \quad (7)$$

Dividing by  $r^2$  gives

$$\frac{1}{\kappa T} \frac{d^2 T}{dt^2} = \frac{1}{R} \frac{d^2 R}{dr^2} + \frac{2}{rR} \frac{dR}{dr} - \frac{n(n+1)}{r^2} = -\frac{1}{\lambda^2}, \quad (8)$$

where a NEGATIVE separation constant has been chosen so that the  $t$  portion remains finite

$$T(t) = C e^{-\kappa t / \lambda^2}. \quad (9)$$

The radial portion then becomes

$$\frac{1}{R} \frac{d^2 R}{dr^2} + \frac{2}{rR} \frac{dR}{dr} - \frac{n(n+1)}{r^2} + \frac{1}{\lambda^2} = 0 \quad (10)$$

$$r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} + \left[ \frac{r^2}{\lambda^2} - n(n+1) \right] R = 0, \quad (11)$$

which is the SPHERICAL BESSEL DIFFERENTIAL EQUATION. If the initial temperature is  $T(r, 0) = 0$  and the boundary condition is  $T(1, t) = 1$ , the solution is

$$T(r, t) = 1 - 2 \sum_{n=1}^{\infty} \frac{J_0(\alpha_n r)}{\alpha_n J_1(\alpha_n)} e^{-\alpha_n^2 t}, \quad (12)$$

where  $\alpha_n$  is the  $n$ th POSITIVE zero of the BESSEL FUNCTION OF THE FIRST KIND  $J_0$ .

### Heaviside Calculus

A method of solving differential equations using FOURIER TRANSFORMS and LAPLACE TRANSFORMS.

see also FOURIER TRANSFORM, LAPLACE TRANSFORM

### Heaviside Step Function

A discontinuous "step" function, also called the UNIT STEP, and defined by

$$H(x) = \begin{cases} 0 & x < 0 \\ \frac{1}{2} & x = 0 \\ 1 & x > 0 \end{cases} \quad (1)$$

It is related to the BOXCAR FUNCTION. The DERIVATIVE is given by

$$\frac{d}{dx} H(x) = \delta(x), \quad (2)$$

where  $\delta(x)$  is the DELTA FUNCTION, and the step function is related to the RAMP FUNCTION  $R(x)$  by

$$\frac{d}{dx} R(x) = -H(x). \quad (3)$$

Bracewell (1965) gives many identities, some of which include the following. Letting  $*$  denote the CONVOLUTION,

$$H(x) * f(x) = \int_{-\infty}^x f(x') dx' \quad (4)$$

$$H(T) * H(T) = \int_{-\infty}^{\infty} H(u) H(T-u) du \quad (5)$$

$$\begin{aligned} &= H(0) \int_0^{\infty} H(T-u) du \\ &= H(0) H(T) \int_0^T du = TH(T). \end{aligned} \quad (6)$$

Additional identities are

$$H(x)H(y) = \begin{cases} H(x) & x > y \\ H(y) & x < y \end{cases} \quad (7)$$

$$\begin{aligned} H(ax+b) &= H\left(x + \frac{b}{a}\right) H(a) + H\left(-x - \frac{b}{a}\right) H(-a) \\ &= \begin{cases} H\left(x + \frac{b}{a}\right) & a > 0 \\ H\left(-x - \frac{b}{a}\right) & a < 0. \end{cases} \end{aligned} \quad (8)$$

The step function obeys the integral identities

$$\int_{-a}^b H(u-u_0) f(u) du = H(u_0) \int_{u_0}^b f(u) du \quad (9)$$

$$\int_{-a}^b H(u_1-u) f(u) du = H(u_1) \int_{-a}^{u_1} f(u) du \quad (10)$$

$$\int_{-a}^b H(u - u_0)H(u_1 - u)f(u) du \\ = H(u_0)H(u_1) \int_{u_0}^{u_1} f(u) du. \quad (11)$$

The Heaviside step function can be defined by the following limits,

$$H(x) = \lim_{t \rightarrow 0} \left[ \frac{1}{2} + \frac{1}{\pi} \tan^{-1} \left( -\frac{x}{t} \right) \right] \quad (12)$$

$$= \frac{1}{2} \lim_{t \rightarrow 0} \operatorname{erfc} \left( -\frac{x}{t} \right) \quad (13)$$

$$= \frac{1}{\sqrt{\pi}} \lim_{t \rightarrow 0} \int_{-s}^{\infty} t^{-1} e^{-u^2/t} du \quad (14)$$

$$= \frac{1}{2} + \frac{1}{\pi} \lim_{t \rightarrow 0} \operatorname{si} \left( \frac{\pi x}{t} \right) \quad (15)$$

$$= \lim_{t \rightarrow 0} \int_{-\infty}^x t^{-1} \operatorname{sinc} \left( \frac{u}{t} \right) du \quad (16)$$

$$= \lim_{t \rightarrow 0} \begin{cases} \frac{1}{2}(1 - e^{-x/t}) & x > 0 \\ -\frac{1}{2}(1 - e^{-x/t}) & x < 0 \end{cases} \quad (17)$$

$$= \lim_{t \rightarrow 0} \int_{-\infty}^x t^{-1} \Lambda \left( \frac{x - \frac{1}{2}t}{t} \right) dx, \quad (18)$$

where  $\Lambda$  is the one-argument TRIANGLE FUNCTION and  $\operatorname{si}(x)$  is the SINE INTEGRAL.

The FOURIER TRANSFORM of the Heaviside step function is given by

$$\mathcal{F}[H(x)] = \int_{-\infty}^{\infty} e^{-2\pi i k x} H(x) dx = \frac{1}{2} \left[ \delta(k) - \frac{i}{\pi k} \right], \quad (19)$$

where  $\delta(k)$  is the DELTA FUNCTION.

### Heawood Conjecture

The bound for the number of colors which are SUFFICIENT for MAP COLORING on a surface of GENUS  $g$ ,

$$\chi(g) = \left\lfloor \frac{1}{2}(7 + \sqrt{48g + 1}) \right\rfloor$$

is the best possible, where  $\lfloor x \rfloor$  is the FLOOR FUNCTION.  $\chi(g)$  is called the CHROMATIC NUMBER, and the first few values for  $g = 0, 1, \dots$  are 4, 7, 8, 9, 10, 11, 12, 12, 13, 13, 14,  $\dots$  (Sloane's A000934).

The fact that  $\chi(g)$  is also NECESSARY was proved by Ringel and Youngs (1968) with two exceptions: the SPHERE (PLANE), and the KLEIN BOTTLE (for which the Heawood FORMULA gives seven, but the correct bound is six). When the FOUR-COLOR THEOREM was proved in 1976, the KLEIN BOTTLE was left as the only exception. The four most difficult cases to prove were  $g = 59, 83, 158$ , and 257.

#### Heegaard Diagram

A diagram expressing how the gluing operation that connects the HANDLEBODIES involved in a HEEGAARD SPLITTING proceeds, usually by showing how the meridians of the HANDLEBODY are mapped.

see also HANDLEBODY, HEEGAARD SPLITTING

#### References

- Rolfsen, D. *Knots and Links*. Wilmington, DE: Publish or Perish Press, p. 239, 1976.

#### Heegaard Splitting

A Heegaard splitting of a connected orientable 3-MANIFOLD  $M$  is any way of expressing  $M$  as the UNION of two (3,1)-HANDLEBODIES along their boundaries. The boundary of such a (3,1)-HANDLEBODY is an orientable SURFACE of some GENUS, which determines the number of HANDLES in the (3,1)-HANDLEBODIES. Therefore, the HANDLEBODIES involved in a Heegaard splitting are the same, but they may be glued together in a strange way along their boundary. A diagram showing how the gluing is done is known as a HEEGAARD DIAGRAM.

#### Heegner Number

The values of  $-d$  for which QUADRATIC FIELDS  $\mathbb{Q}(\sqrt{-d})$  are uniquely factorable into factors of the form  $a + b\sqrt{-d}$ . Here,  $a$  and  $b$  are half-integers, except for  $d = 1$  and  $2$ , in which case they are INTEGERS. The Heegner numbers therefore correspond to DISCRIMINANTS  $-d$  which have CLASS NUMBER  $h(-d)$  equal to 1, except for Heegner numbers  $-1$  and  $-2$ , which correspond to  $d = -4$  and  $-8$ , respectively.

The determination of these numbers is called GAUSS'S CLASS NUMBER PROBLEM, and it is now known that there are only nine Heegner numbers:  $-1$ ,  $-2$ ,  $-3$ ,  $-7$ ,  $-11$ ,  $-19$ ,  $-43$ ,  $-67$ , and  $-163$  (Sloane's A003173), corresponding to discriminants  $-4$ ,  $-8$ ,  $-3$ ,  $-7$ ,  $-11$ ,  $-19$ ,  $-43$ ,  $-67$ , and  $-163$ , respectively.

Heilbronn and Linfoot (1934) showed that if a larger  $d$  existed, it must be  $> 10^9$ . Heegner (1952) published a proof that only nine such numbers exist, but his proof was not accepted as complete at the time. Subsequent

examination of Heegner's proof show it to be "essentially" correct (Conway and Guy 1996).

The Heegner numbers have a number of fascinating connections with amazing results in PRIME NUMBER theory. In particular, the  $j$ -FUNCTION provides stunning connections between  $e$ ,  $\pi$ , and the ALGEBRAIC INTEGERS. They also explain why Euler's PRIME-GENERATING POLYNOMIAL  $n^2 - n + 41$  is so surprisingly good at producing PRIMES.

#### Heesch Number

The Heesch number of a closed plane figure is the maximum number of times that figure can be completely surrounded by copies of itself. The determination of the maximum possible (finite) Heesch number is known as HEESCH'S PROBLEM. The Heesch number of a TRIANGLE, QUADRILATERAL, regular HEXAGON, or any other shape that can TILE or TESSELLATE the plane, is infinity. Conversely, any shape with infinite Heesch number must tile the plane (Eppstein). The largest known (finite) Heesch number is 3, and corresponds to a tile invented by R. Ammann (Senechal 1995).

**Heilbronn Triangle Problem**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Given any arrangement of  $n$  points within a UNIT SQUARE, let  $H_n$  be the smallest value for which there is at least one TRIANGLE formed from three of the points with  $\text{AREA} \leq H_n$ . The first few values are

$$\begin{aligned} H_3 &= \frac{1}{2} \\ H_4 &= \frac{1}{2} \\ H_5 &= \frac{1}{9}\sqrt{3} \\ H_6 &= \frac{1}{8} \\ H_7 &\geq \frac{1}{12} \\ H_8 &\geq \frac{1}{4}(2 - \sqrt{3}) \\ H_9 &\geq \frac{1}{21} \\ H_{10} &\geq \frac{1}{32}(3\sqrt{17} - 11) \\ H_{11} &\geq \frac{1}{27} \\ H_{12} &\geq \frac{1}{33} \\ H_{13} &\geq 0.030 \\ H_{14} &\geq 0.022 \\ H_{15} &\geq 0.020 \\ H_{16} &\geq 0.0175. \end{aligned}$$

Komlós *et al.* (1981, 1982) have shown that there are constants  $c$  such that

$$\frac{c \ln n}{n^2} \leq H_n \leq \frac{C}{n^{8/7 - \epsilon}},$$

for any  $\epsilon > 0$  and all sufficiently large  $n$ .

Using an EQUILATERAL TRIANGLE of unit AREA instead gives the constants

$$\begin{aligned} h_3 &= 1 \\ h_4 &= \frac{1}{3} \\ h_5 &= 3 - 2\sqrt{2} \\ h_6 &= \frac{1}{8}. \end{aligned}$$

**Heine-Borel Theorem**

If a CLOSED SET of points on a line can be covered by a set of intervals so that every point of the set is an interior point of at least one of the intervals, then there exist a finite number of intervals with the covering property.

**Heine Hypergeometric Series**

$$\begin{aligned} {}_r\phi_s \left[ \begin{matrix} \alpha_1, \alpha_2, \dots, \alpha_r \\ \beta_1, \dots, \beta_s \end{matrix}; z \right] \\ \equiv \sum_{n=0}^{\infty} \frac{(\alpha_1; q)_n (\alpha_2; q)_n \cdots (\alpha_r; q)_n}{(q; q)_n (\beta_1; q)_n \cdots (\beta_s; q)_n} z^n, \quad (1) \end{aligned}$$

where

$$\begin{aligned} (a; q)_n &= (1-a)(1-aq)(1-aq^2) \cdots (1-aq^{n-1}), \quad (2) \\ (a; q)_0 &= 1. \end{aligned} \quad (3)$$

In particular,

$${}_2\psi_1(a, b; c; q, z) = \sum_{n=0}^{\infty} \frac{(a; q)_n (b; q)_n z^n}{(q; q)_n (c; q)_n} \quad (4)$$

(Andrews 1986, p. 10). Heine proved the transformation formula

$${}_2\phi_1(a, b; c; q, z) = \frac{(b; q)_{\infty} (az; q)_{\infty}}{(c; q)_{\infty} (z; q)_{\infty}} {}_2\phi_1(c/b, a; az; q, b), \quad (5)$$

and Rogers (1893) obtained the formulas

$$\begin{aligned} {}_2\phi_1(a, b; c; q, z) &= \frac{(c/b; q)_{\infty} (bz; q)_{\infty}}{(z; q)_{\infty} (c; q)_{\infty}} {}_2\phi_1(b, abz/c; bz; q, c/b) \quad (6) \\ {}_2\phi_1(a, b, c; q, z) &= (abz/c; q)_{\infty} (z; q)_{\infty} {}_2\phi_1(c/a, c/b; c; q, abz/c) \quad (7) \end{aligned}$$

(Andrews 1986, pp. 10–11).

### Heisenberg Group

The Heisenberg group  $H^n$  in  $n$  COMPLEX variables is the GROUP of all  $(z, t)$  with  $z \in \mathbb{C}^n$  and  $t \in \mathbb{R}$  having multiplication

$$(w, t)(z, t') = (w + z, t + t' + \Im[w^T z])$$

where  $w^T$  is the conjugate transpose. The Heisenberg group is ISOMORPHIC to the group of MATRICES

$$\begin{bmatrix} 1 & z^T & \frac{1}{2}|z|^2 + it \\ 0 & 1 & z \\ 0 & 0 & 1 \end{bmatrix},$$

and satisfies

$$(z, t)^{-1} = (-z, -t).$$

Every finite-dimensional unitary representation is trivial on  $Z$  and therefore factors to a REPRESENTATION of the quotient  $\mathbb{C}^n$ .

### Helicoid

The MINIMAL SURFACE having a HELIX as its boundary. It is the only RULED MINIMAL SURFACE other than the PLANE (Catalan 1842, do Carmo 1986). For many years, the helicoid remained the only known example of a complete embedded MINIMAL SURFACE of finite topology with infinite CURVATURE. However, in 1992 a second example, known as HOFFMAN'S MINIMAL SURFACE and consisting of a helicoid with a HOLE, was discovered (*Sci. News* 1992).

The equation of a helicoid in CYLINDRICAL COORDINATES is

$$z = c\theta. \quad (1)$$

In CARTESIAN COORDINATES, it is

$$\frac{y}{x} = \tan\left(\frac{z}{c}\right). \quad (2)$$

It can be given in parametric form by

$$x = u \cos v \quad (3)$$

$$y = u \sin v \quad (4)$$

$$z = cu, \quad (5)$$

which has an obvious generalization to the ELLIPTIC HELICOID. The differentials are

$$dx = \cos v \, du - u \sin v \, dv \quad (6)$$

$$dy = \sin v \, du + u \cos v \, dv \quad (7)$$

$$dz = 2cu \, dv, \quad (8)$$

so the LINE ELEMENT on the surface is

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 \\ &= \cos^2 v \, du^2 - 2u \sin v \cos v \, du \, dv + u^2 \sin^2 v \, dv^2 \\ &\quad + \sin^2 v \, du^2 + 2u \sin v \cos v \, du \, dv + u^2 \cos^2 v \, dv^2 \\ &\quad + 4c^2 u^2 \, dv^2 \\ &= (1 + 4c^2 u^2) \, du^2 + u^2 \, dv^2, \end{aligned} \quad (9)$$

and the METRIC components are

$$g_{uu} = 1 + 4c^2 u^2 \quad (10)$$

$$g_{uv} = 0 \quad (11)$$

$$g_{vv} = u^2. \quad (12)$$

From GAUSS'S THEOREMA EGREGIUM, the GAUSSIAN CURVATURE is then

$$K = \frac{4c^2}{(1 + 4c^2 u^2)^2}. \quad (13)$$

The MEAN CURVATURE is

$$H = 0, \quad (14)$$

and the equation for the LINES OF CURVATURE is

$$u = \pm c \sinh(v - k). \quad (15)$$

The helicoid can be continuously deformed into a CATENOID by the transformation

$$x(u, v) = \cos \alpha \sinh v \sin u + \sin \alpha \cosh v \cos u \quad (16)$$

$$y(u, v) = -\cos \alpha \sinh v \cos u + \sin \alpha \cosh v \sin u \quad (17)$$

$$z(u, v) = u \cos \alpha + v \sin \alpha, \quad (18)$$

where  $\alpha = 0$  corresponds to a helicoid and  $\alpha = \pi/2$  to a CATENOID.

If a twisted curve  $C$  (i.e., one with TORSION  $\tau \neq 0$ ) rotates about a fixed axis  $A$  and, at the same time, is displaced parallel to  $A$  such that the speed of displacement is always proportional to the angular velocity of rotation, then  $C$  generates a GENERALIZED HELICOID.

### Helix

A helix is also called a CURVE OF CONSTANT SLOPE. It can be defined as a curve for which the TANGENT

makes a constant ANGLE with a fixed line. The helix is a SPACE CURVE with parametric equations

$$x = r \cos t \quad (1)$$

$$y = r \sin t \quad (2)$$

$$z = ct, \quad (3)$$

where  $c$  is a constant. The CURVATURE of the helix is given by

$$\kappa = \frac{r}{r^2 + c^2}, \quad (4)$$

and the LOCUS of the centers of CURVATURE of a helix is another helix. The ARC LENGTH is given by

$$s = \int \sqrt{x'^2 + y'^2 + z'^2} dt = \sqrt{r^2 + c^2} t. \quad (5)$$

The TORSION of a helix is given by

$$\tau = \frac{1}{r^2(r^2 + c^2)} \begin{vmatrix} -r \sin t & -r \cos t & r \sin t \\ r \cos t & -r \sin t & -r \cos t \\ c & 0 & 0 \end{vmatrix} = \frac{c}{r^2 + c^2}, \quad (6)$$

so

$$\frac{\kappa}{\tau} = \frac{\frac{r}{r^2 + c^2}}{\frac{c}{r^2 + c^2}} = \frac{r}{c}, \quad (7)$$

which is a constant. In fact, LANCRET'S THEOREM states that a NECESSARY and SUFFICIENT condition for a curve to be a helix is that the ratio of CURVATURE to TORSION be constant. The OSCULATING PLANE of the helix is given by

$$\begin{vmatrix} z_1 - r \cos t & z_2 - r \sin t & z_3 - ct \\ -r \sin t & r \cos t & c \\ -r \cos t & -r \sin t & 0 \end{vmatrix} = 0 \quad (8)$$

$$z_1 c \sin t - z_2 c \cos t + (z_3 - ct)r = 0. \quad (9)$$

The MINIMAL SURFACE of a helix is a HELICOID.

**Helly Number**

Given a Euclidean  $n$ -space,

$$H_n \equiv n + 1.$$

see also EUCLIDEAN SPACE, HELLY'S THEOREM

**Helly's Theorem**

If  $F$  is a family of more than  $n$  bounded closed convex sets in Euclidean  $n$ -space  $\mathbb{R}^n$ , and if every  $H_n$  (where  $H_n$  is the HELLY NUMBER) members of  $F$  have at least one point in common, then all the members of  $F$  have at least one point in common.

see also CARATHÉODORY'S FUNDAMENTAL THEOREM, HELLY NUMBER

**Helmholtz Differential Equation**

A PARTIAL DIFFERENTIAL EQUATION which can be written in a SCALAR version

$$\nabla^2 \psi + k^2 \psi = 0, \quad (1)$$

or VECTOR form,

$$\nabla^2 \mathbf{A} + k^2 \mathbf{A} = 0, \quad (2)$$

where  $\nabla^2$  is the LAPLACIAN. When  $k = 0$ , the Helmholtz differential equation reduces to LAPLACE'S EQUATION. When  $k^2 < 0$ , the equation becomes the space part of the diffusion equation.

The Helmholtz differential equation can be solved by SEPARATION OF VARIABLES in only 11 coordinate systems, 10 of which (with the exception of CONFOCAL PARABOLOIDAL COORDINATES) are particular cases of the CONFOCAL ELLIPSOIDAL system: CARTESIAN, CONFOCAL ELLIPSOIDAL, CONFOCAL PARABOLOIDAL, CONICAL, CYLINDRICAL, ELLIPTIC CYLINDRICAL, OBLATE SPHEROIDAL, PARABOLOIDAL, PARABOLIC CYLINDRICAL, PROLATE SPHEROIDAL, and SPHERICAL COORDINATES (Eisenhart 1934). LAPLACE'S EQUATION (the Helmholtz differential equation with  $k = 0$ ) is separable in the two additional BISPHERICAL COORDINATES and TOROIDAL COORDINATES.

If Helmholtz's equation is separable in a 3-D coordinate system, then Morse and Feshbach (1953, pp. 509–510) show that

$$\frac{h_1 h_2 h_3}{h_n^2} = f_n(u_n) g_n(u_i, u_j), \quad (3)$$

where  $i \neq j \neq n$ . The LAPLACIAN is therefore of the form

$$\begin{aligned} \nabla^2 = \frac{1}{h_1 h_2 h_3} \left\{ g_1(u_2, u_3) \frac{\partial}{\partial u_1} \left[ f_1(u_1) \frac{\partial}{\partial u_1} \right] \right. \\ \left. + g_2(u_1, u_3) \frac{\partial}{\partial u_2} \left[ f_2(u_2) \frac{\partial}{\partial u_2} \right] \right. \\ \left. + g_3(u_1, u_2) \frac{\partial}{\partial u_3} \left[ f_3(u_3) \frac{\partial}{\partial u_3} \right] \right\}, \end{aligned} \quad (4)$$

which simplifies to

$$\begin{aligned} \nabla^2 = \frac{1}{h_1^2 f_1} \frac{\partial}{\partial u_1} \left[ f_1(u_1) \frac{\partial}{\partial u_1} \right] \\ + \frac{1}{h_2^2 f_2} \frac{\partial}{\partial u_2} \left[ f_2(u_2) \frac{\partial}{\partial u_2} \right] \\ + \frac{1}{h_3^2 f_3} \frac{\partial}{\partial u_3} \left[ f_3(u_3) \frac{\partial}{\partial u_3} \right]. \end{aligned} \quad (5)$$

Such a coordinate system obeys the ROBERTSON CONDITION, which means that the STÄCKEL DETERMINANT is of the form

$$S = \frac{h_1 h_2 h_3}{f_1(u_1) f_2(u_2) f_3(u_3)}. \quad (6)$$

Coordinate System	Variables	Solution Functions

**Helmholtz Differential Equation—Bipolar Coordinates**

In BIPOLAR COORDINATES, the HELMHOLTZ DIFFERENTIAL EQUATION is not separable, but LAPLACE'S EQUATION is.

see also LAPLACE'S EQUATION—BIPOLAR COORDINATES

**Helmholtz Differential Equation—Cartesian Coordinates**

In 2-D CARTESIAN COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(x, y) = X(x)Y(y), \quad (1)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 X}{dx^2} Y + \frac{d^2 Y}{dy^2} X + k^2 XY = 0. \quad (2)$$

Dividing both sides by  $XY$  gives

$$\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} + k^2 = 0. \quad (3)$$

This leads to the two coupled ordinary differential equations with a separation constant  $m^2$ ,

$$\frac{1}{X} \frac{d^2 X}{dx^2} = m^2 \quad (4)$$

$$\frac{1}{Y} \frac{d^2 Y}{dy^2} = -(m^2 + k^2), \quad (5)$$

where  $X$  and  $Y$  could be interchanged depending on the boundary conditions. These have solutions

$$X = A_m e^{mx} + B_m e^{-mx} \quad (6)$$

$$\begin{aligned} Y &= C_m e^{i\sqrt{m^2+k^2}y} + D_m e^{-i\sqrt{m^2+k^2}y} \\ &= E_m \sin(\sqrt{m^2+k^2}y) + F_m \cos(\sqrt{m^2+k^2}y). \end{aligned} \quad (7)$$

The general solution is then

$$\begin{aligned} F(x, y) &= \sum_{m=1}^{\infty} (A_m e^{mx} + B_m e^{-mx}) \\ &\times [E_m \sin(\sqrt{m^2+k^2}y) + F_m \cos(\sqrt{m^2+k^2}y)]. \end{aligned} \quad (8)$$

In 3-D CARTESIAN COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(x, y, z) = X(x)Y(y)Z(z), \quad (9)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 X}{dx^2} YZ + \frac{d^2 Y}{dy^2} XZ + \frac{d^2 Z}{dz^2} XY + k^2 XYZ = 0. \quad (10)$$

Dividing both sides by  $XYZ$  gives

$$\frac{1}{X} \frac{d^2 X}{dx^2} + \frac{1}{Y} \frac{d^2 Y}{dy^2} + \frac{1}{Z} \frac{d^2 Z}{dz^2} + k^2 = 0. \quad (11)$$

This leads to the three coupled differential equations

$$\frac{1}{X} \frac{d^2 X}{dx^2} = l^2 \quad (12)$$

$$\frac{1}{Y} \frac{d^2 Y}{dy^2} = m^2 \quad (13)$$

$$\frac{1}{Z} \frac{d^2 Z}{dz^2} = -(k^2 + l^2 + m^2), \quad (14)$$

where  $X$ ,  $Y$ , and  $Z$  could be permuted depending on boundary conditions. The general solution is therefore

$$\begin{aligned} F(x, y, z) &= \sum_{l=1}^{\infty} \sum_{m=1}^{\infty} (A_l e^{lx} + B_l e^{-lx})(C_m e^{my} + D_m e^{-my}) \\ &\times (E_{lm} e^{-i\sqrt{k^2+l^2+m^2}z} + F_{lm} e^{i\sqrt{k^2+l^2+m^2}z}). \end{aligned} \quad (15)$$

### References

### Helmholtz Differential Equation—Circular Cylindrical Coordinates

In CYLINDRICAL COORDINATES, the SCALE FACTORS are  $h_r = 1$ ,  $h_\theta = r$ ,  $h_z = 1$  and the separation functions are  $f_1(r) = r$ ,  $f_2(\theta) = 1$ ,  $f_3(z) = 1$ , so the STÄCKEL DETERMINANT is 1. Attempt SEPARATION OF VARIABLES by writing

$$F(r, \theta, z) = R(r)\Theta(\theta)Z(z), \quad (1)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 R}{dr^2} \Theta Z + \frac{1}{r} \frac{dR}{dr} \Theta Z + \frac{1}{r^2} \frac{d^2 \Theta}{d\theta^2} RZ + \frac{d^2 Z}{dz^2} R\Theta + k^2 R\Theta Z = 0. \quad (2)$$

Now divide by  $R\Theta Z$ ,

$$\left( \frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{r}{R} \frac{dR}{dr} \right) + \frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta} + \frac{d^2 Z}{dz^2} \frac{r^2}{Z} + k^2 = 0, \quad (3)$$

so the equation has been separated. Since the solution must be periodic in  $\Theta$  from the definition of the circular cylindrical coordinate system, the solution to the second part of (3) must have a NEGATIVE separation constant

$$\frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta} = -(k^2 + m^2), \quad (4)$$

which has a solution

$$\Theta(\theta) = C_m e^{-i\sqrt{k^2+m^2}\theta} + D_m e^{i\sqrt{k^2+m^2}\theta}. \quad (5)$$

Plugging (5) back into (3) gives

$$\frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{r}{R} \frac{dR}{dr} - m^2 + \frac{d^2 Z}{dz^2} \frac{r^2}{Z} = 0 \quad (6)$$

$$\frac{1}{R} \frac{d^2 R}{dr^2} + \frac{1}{rR} \frac{dR}{dr} - \frac{m^2}{r^2} + \frac{d^2 Z}{dz^2} \frac{1}{Z} = 0. \quad (7)$$

The solution to the second part of (7) must not be sinusoidal at  $\pm\infty$  for a physical solution, so the differential equation has a POSITIVE separation constant

$$\frac{d^2 Z}{dz^2} \frac{1}{Z} = n^2, \quad (8)$$

and the solution is

$$Z(z) = E_n e^{-nz} + F_n e^{nz}. \quad (9)$$

Plugging (9) back into (7) and multiplying through by  $R$  yields

$$\frac{d^2 R}{dr^2} + \frac{1}{r} \frac{dR}{dr} + \left( n^2 - \frac{m^2}{r^2} \right) R = 0 \quad (10)$$

$$\frac{1}{n^2} \frac{d^2 R}{dr^2} + \frac{1}{(nr)} \frac{1}{n} \frac{dR}{dr} + \left[ 1 - \frac{m^2}{(nr)^2} \right] R = 0 \quad (11)$$

$$\frac{d^2 R}{d(nr)^2} + \frac{1}{(nr)} \frac{dR}{d(nr)} + \left[ 1 - \frac{m^2}{(nr)^2} \right] R = 0. \quad (12)$$

This is the BESSEL DIFFERENTIAL EQUATION, which has a solution

$$R(r) = A_{mn} J_m(nr) + B_{mn} Y_m(nr), \quad (13)$$

where  $J_n(x)$  and  $Y_n(x)$  are BESSEL FUNCTIONS OF THE FIRST and SECOND KINDS, respectively. The general solution is therefore

$$\begin{aligned} F(r, \theta, z) &= \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} [A_{mn} J_m(nr) + B_{mn} Y_m(nr)] \\ &\times (C_m e^{-i\sqrt{k^2+m^2}\theta} + D_m e^{i\sqrt{k^2+m^2}\theta}) (E_n e^{-nz} + F_n e^{nz}). \end{aligned} \quad (14)$$

Actually, the HELMHOLTZ DIFFERENTIAL EQUATION is separable for general  $k$  of the form

$$k^2(r, \theta, z) = f(r) + \frac{g(\theta)}{r^2} + h(z) + k'^2. \quad (15)$$

see also CYLINDRICAL COORDINATES, HELMHOLTZ DIFFERENTIAL EQUATION

#### Helmholtz Differential Equation—Confocal Ellipsoidal Coordinates

Using the NOTATION of Byerly (1959, pp. 252-253), LAPLACE'S EQUATION can be reduced to

$$\nabla^2 F = (\mu^2 - \nu^2) \frac{\partial^2 F}{\partial \alpha^2} + (\lambda^2 - \nu^2) \frac{\partial^2 F}{\partial \beta^2} + (\lambda^2 - \mu^2) \frac{\partial^2 F}{\partial \gamma^2} = 0, \quad (1)$$

where

$$\begin{aligned} \alpha &= c \int_c^\lambda \frac{d\lambda}{\sqrt{(\lambda^2 - b^2)(\lambda^2 - c^2)}} \\ &= F\left[\frac{b}{c}, \frac{\pi}{2}\right] - F\left[\frac{b}{c}, \sin^{-1}\left(\frac{c}{\lambda}\right)\right] \end{aligned} \quad (2)$$

$$\begin{aligned} \beta &= c \int_b^\mu \frac{d\mu}{\sqrt{(c^2 - \mu^2)(\mu^2 - b^2)}} \\ &= F\left[\sqrt{1 - b^2 - c^2}, \sin^{-1}\left(\sqrt{\frac{1 - \frac{b^2}{c^2}}{1 - \frac{\mu^2}{c^2}}}\right)\right] \end{aligned} \quad (3)$$

$$\begin{aligned} \gamma &= c \int_0^\nu \frac{d\nu}{\sqrt{(b^2 - \nu^2)(c^2 - \nu^2)}} \\ &= F\left[\frac{b}{c}, \sin^{-1}\left(\frac{\nu}{b}\right)\right]. \end{aligned} \quad (4)$$

In terms of  $\alpha$ ,  $\beta$ , and  $\gamma$ ,

$$\lambda = c \operatorname{dc}\left(\alpha, \frac{b}{c}\right) \quad (5)$$

$$\mu = b \operatorname{nd}\left(\beta, \sqrt{1 - \frac{b^2}{c^2}}\right) \quad (6)$$

$$\nu = b \operatorname{sn}\left(\gamma, \frac{b}{c}\right). \quad (7)$$

Equation (1) is not separable using a function of the form

$$F = L(\alpha)M(\beta)N(\gamma), \quad (8)$$

but it is if we let

$$\frac{1}{L} \frac{d^2 L}{d\alpha^2} = \sum a_k \lambda^k \quad (9)$$

$$\frac{1}{M} \frac{d^2 M}{d\beta^2} = \sum b_k \mu^k \quad (10)$$

$$\frac{1}{N} \frac{d^2 N}{d\gamma^2} = \sum c_k \nu^k. \quad (11)$$

These give

$$a_0 = -b_0 = c_0 \quad (12)$$

$$a_2 = -b_2 = c_2, \quad (13)$$

and all others terms vanish. Therefore (1) can be broken up into the equations

$$\frac{d^2 L}{d\alpha^2} = (a_0 + a_2 \lambda^2) L \quad (14)$$

$$\frac{d^2 M}{d\beta^2} = -(a_0 + a_2 \mu^2) M \quad (15)$$

$$\frac{d^2 N}{d\gamma^2} = (a_0 + a_2 \nu^2) N. \quad (16)$$

For future convenience, now write

$$a_0 = -(b^2 + c^2)p \quad (17)$$

$$a_2 = m(m+1), \quad (18)$$

then

$$\frac{d^2 L}{d\alpha^2} - [m(m+1)\lambda^2 - (b^2 + c^2)p]L = 0 \quad (19)$$

$$\frac{d^2 M}{d\beta^2} + [m(m+1)\mu^2 - (b^2 + c^2)p]M = 0 \quad (20)$$

$$\frac{d^2 N}{d\gamma^2} - [m(m+1)\nu^2 - (b^2 + c^2)p]N = 0. \quad (21)$$

Now replace  $\alpha$ ,  $\beta$ , and  $\gamma$  to obtain

$$(\lambda^2 - b^2)(\lambda^2 - c^2) \frac{d^2 L}{d\lambda^2} + \lambda(\lambda^2 - b^2 + \lambda^2 - c^2) \frac{dL}{d\lambda} - [m(m+1)\lambda^2 - (b^2 + c^2)p]L = 0 \quad (22)$$

$$(\mu^2 - b^2)(\mu^2 - c^2) \frac{d^2 M}{d\mu^2} + \mu(\mu^2 - b^2 + \mu^2 - c^2) \frac{dM}{d\mu} - [m(m+1)\mu^2 - (b^2 + c^2)p]M = 0 \quad (23)$$

$$(\nu^2 - b^2)(\nu^2 - c^2) \frac{d^2 N}{d\nu^2} + \nu(\nu^2 - b^2 + \nu^2 - c^2) \frac{dN}{d\nu} - [m(m+1)\nu^2 - (b^2 + c^2)p]N = 0. \quad (24)$$

Each of these is a LAMÉ'S DIFFERENTIAL EQUATION, whose solution is called an ELLIPSOIDAL HARMONIC. Writing

$$L(\lambda) = E_m^p(\lambda) \quad (25)$$

$$M(\lambda) = E_m^p(\mu) \quad (26)$$

$$N(\lambda) = E_m^p(\nu) \quad (27)$$

gives the solution to (1) as a product of ELLIPSOIDAL HARMONICS  $E_m^p(x)$ .

$$F = E_m^p(\lambda)E_m^p(\mu)E_m^p(\nu). \quad (28)$$

### Helmholtz Differential Equation—Conical Coordinates

In CONICAL COORDINATES, LAPLACE'S EQUATION can be written

$$\frac{\partial^2 V}{\partial \alpha^2} + \frac{\partial^2 V}{\partial \beta^2} + (\mu^2 - \nu^2) \frac{\partial}{\partial \lambda} \left( \lambda^2 \frac{\partial V}{\partial \lambda} \right) = 0, \quad (1)$$

where

$$\alpha = \int_a^\mu \frac{d\mu}{\sqrt{(\mu^2 - a^2)(b^2 - \mu^2)}} \quad (2)$$

$$\beta = \int_0^\nu \frac{d\nu}{\sqrt{(a^2 - \nu^2)(b^2 - \nu^2)}} \quad (3)$$

(Byerly 1959). Letting

$$V = U(u)R(r) \quad (4)$$

breaks (1) into the two equations,

$$\frac{d}{dr} \left( r^2 \frac{dR}{dr} \right) = m(m+1)R \quad (5)$$

$$\frac{\partial^2 U}{\partial \alpha^2} + \frac{\partial^2 U}{\partial \beta^2} + m(m+1)(\mu^2 - \nu^2)U = 0. \quad (6)$$

Solving these gives

$$R(r) = Ar^m + Br^{-m-1} \quad (7)$$

$$U(u) = E_m^p(\mu)E_m^p(\nu), \quad (8)$$

where  $E_m^p$  are ELLIPSOIDAL HARMONICS. The regular solution is therefore

$$V = Ar^m E_m^p(\mu)E_m^p(\nu). \quad (9)$$

However, because of the cylindrical symmetry, the solution  $E_m^p(\mu)E_m^p(\nu)$  is an  $m$ th degree SPHERICAL HARMONIC.

### Helmholtz Differential Equation—Elliptic Cylindrical Coordinates

In ELLIPTIC CYLINDRICAL COORDINATES, the SCALE FACTORS are  $h_u = h_v = a\sqrt{\sinh^2 u + \sin^2 v}$ ,  $h_z = 1$ ,

and the separation functions are  $f_1(u) = f_2(v) = f_3(z) = 1$ , giving a STÄCKEL DETERMINANT of  $S = a^2(\sin^2 u + \sinh^2 v)$ . The Helmholtz differential equation is

$$\frac{1}{a^2(\sinh^2 u + \sin^2 v)} \left( \frac{\partial^2 F}{\partial u^2} + \frac{\partial^2 F}{\partial v^2} \right) + \frac{\partial^2 F}{\partial z^2} + k^2 = 0. \quad (1)$$

Attempt SEPARATION OF VARIABLES by writing

$$F(u, v, z) = U(u)V(v)Z(z), \quad (2)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{Z}{\sinh^2 u + \sin^2 v} \left( V \frac{d^2 U}{du^2} + U \frac{d^2 V}{dv^2} \right) + UV \frac{d^2 Z}{dz^2} + k^2 UVZ = 0. \quad (3)$$

Now divide by  $UVZ$  to give

$$\frac{1}{\sinh^2 u + \sin^2 v} \left( \frac{1}{U} \frac{d^2 U}{du^2} + \frac{1}{V} \frac{d^2 V}{dv^2} \right) + \frac{1}{Z} \frac{d^2 Z}{dz^2} + k^2 = 0. \quad (4)$$

Separating the  $Z$  part,

$$\frac{1}{Z} \frac{d^2 Z}{dz^2} = -(k^2 + m^2) \quad (5)$$

$$\frac{1}{\sinh^2 u + \sin^2 v} \left( \frac{1}{U} \frac{d^2 U}{du^2} + \frac{1}{V} \frac{d^2 V}{dv^2} \right) = m^2, \quad (6)$$

so

$$\frac{d^2 Z}{dz^2} = -(k^2 + m^2)Z, \quad (7)$$

which has the solution

$$Z(z) = A \cos(\sqrt{k^2 + m^2} z) + B \sin(\sqrt{k^2 + m^2} z). \quad (8)$$

Rewriting (6) gives

$$\left( \frac{1}{U} \frac{d^2 U}{du^2} - m^2 \sinh^2 u \right) + \left( \frac{1}{V} \frac{d^2 V}{dv^2} - m^2 \sin^2 v \right) = 0, \quad (9)$$

which can be separated into

$$\frac{1}{U} \frac{d^2 U}{du^2} - m^2 \sinh^2 u = c \quad (10)$$

$$c + \frac{1}{V} \frac{d^2 V}{dv^2} - m^2 \sin^2 v = 0, \quad (11)$$

so

$$\frac{d^2 U}{du^2} - (c + m^2 \sinh^2 u)U = 0 \quad (12)$$

$$\frac{d^2 V}{dv^2} + (c - m^2 \sin^2 v)V = 0. \quad (13)$$

Now use

$$\sinh^2 u = \frac{1}{2}[1 - \cosh(2u)] \quad (14)$$

$$\sin^2 v = \frac{1}{2}[1 - \cos(2v)] \quad (15)$$

to obtain

$$\frac{d^2 U}{du^2} - \{c + \frac{1}{2}m^2[1 - \cosh(2u)]\}U = 0 \quad (16)$$

$$\frac{d^2 V}{dv^2} + \{c + \frac{1}{2}m^2[1 - \cos(2v)]\}V = 0. \quad (17)$$

Regrouping gives

$$\frac{d^2 U}{du^2} - [(c + \frac{1}{2}m^2) - \frac{1}{4}m^2 2 \cosh(2u)]U = 0 \quad (18)$$

$$\frac{d^2 V}{dv^2} + [(c + \frac{1}{2}m^2) - \frac{1}{4}m^2 2 \cos(2v)]V = 0. \quad (19)$$

Let  $b \equiv \frac{1}{2}m^2 + c$  and  $q \equiv \frac{1}{4}m^2$ , then these become

$$\frac{d^2 U}{du^2} - [b - 2q \cosh(2u)]U = 0 \quad (20)$$

$$\frac{d^2 V}{dv^2} + [b - 2q \cos(2v)]V = 0. \quad (21)$$

Here, (21) is the MATHIEU DIFFERENTIAL EQUATION and (20) is the modified MATHIEU DIFFERENTIAL EQUATION. These solutions are known as MATHIEU FUNCTIONS.

#### Helmholtz Differential Equation—Parabolic Coordinates

The SCALE FACTORS are  $h_u = h_v = \sqrt{u^2 + v^2}$ ,  $h_\theta = uv$  and the separation functions are  $f_1(u) = u$ ,  $f_2(v) = v$ ,  $f_3(\theta) = 1$ , given a STÄCKEL DETERMINANT of  $S = u^2 + v^2$ . The LAPLACIAN is

$$\frac{1}{u^2 + v^2} \left( \frac{1}{u} \frac{\partial F}{\partial u} + \frac{\partial^2 F}{\partial u^2} + \frac{1}{v} \frac{\partial F}{\partial v} + \frac{\partial^2 F}{\partial v^2} \right) + \frac{1}{u^2 v^2} \frac{\partial^2 F}{\partial \theta^2} + k^2 = 0. \quad (1)$$

Attempt SEPARATION OF VARIABLES by writing

$$F(u, v, z) \equiv U(u)V(v)\Theta(\theta), \quad (2)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{1}{u^2 + v^2} \left[ V\Theta \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) + U\Theta \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) \right] + k^2 UV\Theta = 0. \quad (3)$$

Now divide by  $UV\Theta$ ,

$$\frac{u^2 v^2}{u^2 + v^2} \left[ \frac{1}{U} \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) + \frac{1}{V} \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) \right] + \frac{1}{\Theta} \frac{d^2\Theta}{d\theta^2} + k^2 = 0. \quad (4)$$

Separating the  $\Theta$  part,

$$\frac{1}{\Theta} \frac{d^2\Theta}{d\theta^2} = -(k^2 + m^2) \quad (5)$$

$$\frac{u^2 v^2}{u^2 + v^2} \left[ \frac{1}{U} \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) + \frac{1}{V} \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) \right] = k^2, \quad (6)$$

so

$$\frac{d^2\Theta}{d\theta^2} = -(k^2 + m^2)\Theta, \quad (7)$$

which has solution

$$\Theta(\theta) = A \cos(\sqrt{k^2 + m^2} \theta) + B \sin(\sqrt{k^2 + m^2} \theta), \quad (8)$$

and

$$\left[ \frac{1}{U} \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) \right] + \left[ \frac{1}{V} \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) \right] - k^2 \frac{u^2 + v^2}{u^2 v^2} = 0 \quad (9)$$

$$\left[ \frac{1}{U} \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) - \frac{k^2}{u^2} \right] + \left[ \frac{1}{V} \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) - \frac{k^2}{v^2} \right] = 0. \quad (10)$$

This can be separated

$$\frac{1}{U} \left( \frac{1}{u} \frac{dU}{du} + \frac{d^2U}{du^2} \right) - \frac{k^2}{u^2} = c \quad (11)$$

$$\frac{1}{V} \left( \frac{1}{v} \frac{dV}{dv} + \frac{d^2V}{dv^2} \right) - \frac{k^2}{v^2} = -c, \quad (12)$$

so

$$u^2 \frac{d^2U}{du^2} + \frac{dU}{du} - (c + k^2)U = 0 \quad (13)$$

$$v^2 \frac{d^2V}{dv^2} + \frac{dV}{dv} + (c - k^2)V = 0. \quad (14)$$

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 514–515 and 660, 1953.

### Helmholtz Differential Equation—Parabolic Cylindrical Coordinates

In PARABOLIC CYLINDRICAL COORDINATES, the SCALE FACTORS are  $h_u = h_v = \sqrt{u^2 + v^2}$ ,  $h_z = 1$  and the separation functions are  $f_1(u) = f_2(v) = f_3(z) = 1$ , giving STÄCKEL DETERMINANT of  $S = u^2 + v^2$ . The HELMHOLTZ DIFFERENTIAL EQUATION is

$$\frac{1}{u^2 + v^2} \left( \frac{\partial^2 F}{\partial u^2} + \frac{\partial^2 F}{\partial v^2} \right) + \frac{\partial^2 F}{\partial z^2} + k^2 = 0. \quad (1)$$

Attempt SEPARATION OF VARIABLES by writing

$$F(u, v, z) \equiv U(u)V(v)Z(z), \quad (2)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{1}{u^2 + v^2} \left( VZ \frac{d^2U}{du^2} + UZ \frac{d^2V}{dv^2} \right) + UV \frac{d^2Z}{dz^2} + k^2 UVZ = 0. \quad (3)$$

Divide by  $UVZ$ ,

$$\frac{1}{u^2 + v^2} \left( \frac{1}{U} \frac{d^2U}{du^2} + \frac{1}{V} \frac{d^2V}{dv^2} \right) + \frac{1}{Z} \frac{d^2Z}{dz^2} + k^2 = 0. \quad (4)$$

Separating the  $Z$  part,

$$\frac{1}{Z} \frac{d^2Z}{dz^2} = -(k^2 + m^2) \quad (5)$$

$$\frac{1}{u^2 + v^2} \left( \frac{1}{U} \frac{d^2U}{du^2} + \frac{1}{V} \frac{d^2V}{dv^2} \right) - k^2 = 0 \quad (6)$$

$$\frac{1}{U} \frac{d^2U}{du^2} + \frac{1}{V} \frac{d^2V}{dv^2} - k^2(u^2 + v^2) = 0, \quad (7)$$

so

$$\frac{d^2Z}{dz^2} = -(k^2 + m^2)Z, \quad (8)$$

which has solution

$$Z(z) = A \cos(\sqrt{k^2 + m^2} z) + B \sin(\sqrt{k^2 + m^2} z), \quad (9)$$

and

$$\left(\frac{1}{U} \frac{d^2 U}{du^2} - k^2 u^2\right) + \left(\frac{1}{V} \frac{d^2 V}{dv^2} - k^2 v^2\right) = 0. \quad (10)$$

This can be separated

$$\frac{1}{U} \frac{d^2 U}{du^2} - k^2 u^2 = c \quad (11)$$

$$\frac{1}{V} \frac{d^2 V}{dv^2} - k^2 v^2 = -c, \quad (12)$$

so

$$\frac{d^2 U}{du^2} - (c + k^2 u^2)U = 0 \quad (13)$$

$$\frac{d^2 V}{dv^2} + (c - k^2 v^2)V = 0. \quad (14)$$

These are the WEBER DIFFERENTIAL EQUATIONS, and the solutions are known as PARABOLIC CYLINDER FUNCTIONS.

see also PARABOLIC CYLINDER FUNCTION, PARABOLIC CYLINDRICAL COORDINATES, WEBER DIFFERENTIAL EQUATIONS

#### References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 515 and 658, 1953.

### Helmholtz Differential Equation—Polar Coordinates

In 2-D POLAR COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(r, \theta) = R(r)\Theta(\theta), \quad (1)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 R}{dr^2} \Theta + \frac{1}{r} \frac{dR}{dr} \Theta + \frac{1}{r^2} \frac{d^2 \Theta}{d\theta^2} R + k^2 R \Theta = 0. \quad (2)$$

Divide both sides by  $R\Theta$

$$\left(\frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{r}{R} \frac{dR}{dr}\right) + \left(\frac{1}{\Theta} \frac{d^2 \Theta}{d\theta^2} + k^2\right) = 0. \quad (3)$$

The solution to the second part of (3) must be periodic, so the differential equation is

$$\frac{d^2 \Theta}{d\theta^2} + \frac{1}{\Theta} = -(k^2 + m^2), \quad (4)$$

which has solutions

$$\begin{aligned} \Theta(\theta) &= c_1 e^{i\sqrt{k^2+m^2}\theta} + c_2 e^{-i\sqrt{k^2+m^2}\theta} \\ &= c_3 \sin(\sqrt{k^2+m^2}\theta) + c_4 \cos(\sqrt{k^2+m^2}\theta). \end{aligned} \quad (5)$$

Plug (4) back into (3)

$$r^2 R'' + rR' - m^2 R = 0. \quad (6)$$

This is an EULER DIFFERENTIAL EQUATION with  $\alpha \equiv 1$  and  $\beta \equiv -m^2$ . The roots are  $r = \pm m$ . So for  $m = 0$ ,  $r = 0$  and the solution is

$$R(r) = c_1 + c_2 \ln r. \quad (7)$$

But since  $\ln r$  blows up at  $r = 0$ , the only possible physical solution is  $R(r) = c_1$ . When  $m > 0$ ,  $r = \pm m$ , so

$$R(r) = c_1 r^m + c_2 r^{-m}. \quad (8)$$

But since  $r^{-m}$  blows up at  $r = 0$ , the only possible physical solution is  $R_m(r) = c_1 r^m$ . The solution for  $R$  is then

$$R_m(r) = c_m r^m \quad (9)$$

for  $m = 0, 1, \dots$  and the general solution is

$$\begin{aligned} F(r, \theta) &= \sum_{m=0}^{\infty} [a_m r^m \sin(\sqrt{k^2 + m^2} \theta) \\ &\quad + b_m r^m \cos(\sqrt{k^2 + m^2} \theta)]. \end{aligned} \quad (10)$$

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 502–504, 1953.

### Helmholtz Differential Equation—Prolate Spheroidal Coordinates

As shown by Morse and Feshbach (1953) and Arfken (1970), the HELMHOLTZ DIFFERENTIAL EQUATION is separable in PROLATE SPHEROIDAL COORDINATES.

#### References

Arfken, G. "Prolate Spheroidal Coordinates ( $u, v, \phi$ ).", §2.10 in *Mathematical Methods for Physicists*, 2nd ed. Orlando, FL: Academic Press, pp. 103–107, 1970.  
Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, p. 661, 1953.

### Helmholtz Differential Equation—Spherical Coordinates

In SPHERICAL COORDINATES, the SCALE FACTORS are  $h_r = 1$ ,  $h_\theta = r \sin \phi$ ,  $h_\phi = r$ , and the separation functions are  $f_1(r) = r^2$ ,  $f_2(\theta) = 1$ ,  $f_3(\phi) = \sin \phi$ , giving a STÄCKEL DETERMINANT of  $S = 1$ . The LAPLACIAN is

$$\begin{aligned} \nabla^2 &\equiv \frac{1}{r^2} \frac{\partial}{\partial r} \left( r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2 \sin^2 \phi} \frac{\partial^2}{\partial \theta^2} \\ &\quad + \frac{1}{r^2 \sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial}{\partial \phi} \right). \end{aligned} \quad (1)$$

To solve the HELMHOLTZ DIFFERENTIAL EQUATION in SPHERICAL COORDINATES, attempt SEPARATION OF VARIABLES by writing

$$F(r, \theta, \phi) = R(r)\Theta(\theta)\Phi(\phi). \quad (2)$$

Then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{d^2 R}{dr^2} \Phi \Theta + \frac{2}{r} \frac{dR}{dr} \Phi \Theta + \frac{1}{r^2 \sin^2 \phi} \frac{d^2 \Theta}{d\theta^2} \Phi R + \frac{\cos \phi}{r^2 \sin \phi} \frac{d\Phi}{d\phi} \Theta R + \frac{1}{r^2} \frac{d^2 \Phi}{d\phi^2} \Theta R = 0. \quad (3)$$

Now divide by  $R\Theta\Phi$ ,

$$\begin{aligned} & \frac{r^2 \sin^2 \phi}{\Phi R \Theta} \frac{d^2 R}{dr^2} + \frac{2}{r} \frac{r^2 \sin^2 \phi}{\Phi R \Theta} \frac{dR}{dr} \\ & + \frac{1}{r^2 \sin^2 \phi} \frac{r^2 \sin^2 \phi}{\Phi R \Theta} \frac{d^2 \Theta}{d\theta^2} + \frac{\cos \phi}{r^2 \sin \phi} \frac{r^2 \sin^2 \phi}{\Phi R \Theta} \frac{d\Phi}{d\phi} \\ & + \frac{1}{r^2} \frac{r^2 \sin^2 \phi}{\Phi R \Theta} \frac{d^2 \Phi}{d\phi^2} \Theta R = 0 \end{aligned} \quad (4)$$

$$\begin{aligned} & \left( \frac{r^2 \sin^2 \phi}{R} \frac{d^2 R}{dr^2} + \frac{2r \sin^2 \phi}{R} \frac{dR}{dr} \right) + \left( \frac{1}{\Theta} \frac{d^2 \Theta}{d\theta^2} \right) \\ & + \left( \frac{\cos \phi \sin \phi}{\Phi} \frac{d\Phi}{d\phi} + \frac{\sin^2 \phi}{\Phi} \frac{d^2 \Phi}{d\phi^2} \right) = 0. \end{aligned} \quad (5)$$

The solution to the second part of (5) must be sinusoidal, so the differential equation is

$$\frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta} = -m^2, \quad (6)$$

which has solutions which may be defined either as a COMPLEX function with  $m = -\infty, \dots, \infty$

$$\Theta(\theta) = A_m e^{im\theta}, \quad (7)$$

or as a sum of REAL sine and cosine functions with  $m = -\infty, \dots, \infty$

$$\Theta(\theta) = S_m \sin(m\theta) + C_m \cos(m\theta). \quad (8)$$

Plugging (6) back into (7),

$$\begin{aligned} & \frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} - \frac{1}{\sin^2 \phi} \left( m^2 + \frac{\cos \phi \sin \phi}{\Phi} \right) \frac{d\Phi}{d\phi} \\ & + \frac{\sin^2 \phi}{\Phi} \frac{d^2 \Phi}{d\phi^2} = 0. \end{aligned} \quad (9)$$

The radial part must be equal to a constant

$$\frac{r^2}{R} \frac{d^2 R}{dr^2} + \frac{2r}{R} \frac{dR}{dr} = l(l+1) \quad (10)$$

$$r^2 \frac{d^2 R}{dr^2} + 2r \frac{dR}{dr} = l(l+1)R. \quad (11)$$

But this is the EULER DIFFERENTIAL EQUATION, so we try a series solution of the form

$$R = \sum_{n=0}^{\infty} a_n r^{n+c}. \quad (12)$$

Then

$$\begin{aligned} & r^2 \sum_{n=0}^{\infty} (n+c)(n+c-1) a_n r^{n+c-2} + 2r \sum_{n=0}^{\infty} (n+c) a_n r^{n+c-1} \\ & - l(l+1) \sum_{n=0}^{\infty} a_n r^{n+c} = 0 \end{aligned} \quad (13)$$

$$\begin{aligned} & \sum_{n=0}^{\infty} (n+c)(n+c-1) a_n r^{n+c} + 2 \sum_{n=0}^{\infty} (n+c) a_n r^{n+c} \\ & - l(l+1) \sum_{n=0}^{\infty} a_n r^{n+c} = 0 \end{aligned} \quad (14)$$

$$\sum_{n=0}^{\infty} [(n+c)(n+c+1) - l(l+1)] a_n r^{n+c} = 0. \quad (15)$$

This must hold true for all POWERS of  $r$ . For the  $r^c$  term (with  $n=0$ ),

$$c(c+1) = l(l+1), \quad (16)$$

which is true only if  $c = l, -l-1$  and all other terms vanish. So  $a_n = 0$  for  $n \neq l, -l-1$ . Therefore, the solution of the  $R$  component is given by

$$R_l(r) = A_l r^l + B_l r^{-l-1}. \quad (17)$$

Plugging (17) back into (9),

$$l(l+1) - \frac{m^2}{\sin^2 \phi} + \frac{\cos \phi}{\sin \phi} \frac{1}{\Phi} \frac{d\Phi}{d\phi} + \frac{1}{\Phi} \frac{d^2 \Phi}{d\phi^2} = 0 \quad (18)$$

$$\Phi'' + \frac{\cos \phi}{\sin \phi} \Phi' + \left[ l(l+1) - \frac{m^2}{\sin^2 \phi} \right] \Phi = 0, \quad (19)$$

which is the associated LEGENDRE DIFFERENTIAL EQUATION for  $x = \cos \phi$  and  $m = 0, \dots, l$ . The general COMPLEX solution is therefore

$$\begin{aligned} & \sum_{l=0}^{\infty} \sum_{m=-l}^l (A_l r^l + B_l r^{-l-1}) P_l^m(\cos \phi) e^{-im\theta} \\ & \equiv \sum_{l=0}^{\infty} \sum_{m=-l}^l (A_l r^l + B_l r^{-l-1}) Y_l^m(\theta, \phi), \end{aligned} \quad (20)$$

where

$$Y_l^m(\theta, \phi) \equiv P_l^m(\cos \phi) e^{-im\theta} \quad (21)$$

are the (COMPLEX) SPHERICAL HARMONICS. The general REAL solution is

$$\begin{aligned} & \sum_{l=0}^{\infty} \sum_{m=0}^l (A_l r^l + B_l r^{-l-1}) P_l^m(\cos \phi) \\ & \times [S_m \sin(m\theta) + C_m \cos(m\theta)]. \end{aligned} \quad (22)$$

Some of the normalization constants of  $P_l^m$  can be absorbed by  $S_m$  and  $C_m$ , so this equation may appear in the form

$$\begin{aligned} & \sum_{l=0}^{\infty} \sum_{m=0}^l (A_l r^l + B_l r^{-l-1}) P_l^m(\cos \phi) \\ & \quad \times [S_l^m \sin(m\theta) + C_l^m \cos(m\theta)] \\ \equiv & \sum_{l=0}^{\infty} \sum_{m=0}^l (A_l r^l + B_l r^{-l-1}) \\ & \quad \times [S_l^m Y_l^{m(o)}(\theta, \phi) + C_l^m Y_l^{m(e)}(\theta, \phi)], \quad (23) \end{aligned}$$

where

$$Y_l^{m(o)}(\theta, \phi) \equiv P_l^m(\cos \theta) \sin(m\theta) \quad (24)$$

$$Y_l^{m(e)}(\theta, \phi) \equiv P_l^m(\cos \theta) \cos(m\theta) \quad (25)$$

are the EVEN and ODD (real) SPHERICAL HARMONICS. If azimuthal symmetry is present, then  $\Theta(\theta)$  is constant and the solution of the  $\Phi$  component is a LEGENDRE POLYNOMIAL  $P_l(\cos \phi)$ . The general solution is then

$$F(r, \phi) = \sum_{l=0}^{\infty} (A_l r^l + B_l r^{-l-1}) P_l(\cos \phi). \quad (26)$$

Actually, the equation is separable under the more general condition that  $k^2$  is of the form

$$k^2(r, \theta, \phi) = f(r) + \frac{g(\theta)}{r^2} + \frac{h(\phi)}{r^2 \sin \theta} + k'^2. \quad (27)$$

### Helmholtz Differential Equation—Spherical Surface

On the surface of a SPHERE, attempt SEPARATION OF VARIABLES in SPHERICAL COORDINATES by writing

$$F(\theta, \phi) = \Theta(\theta)\Phi(\phi), \quad (1)$$

then the HELMHOLTZ DIFFERENTIAL EQUATION becomes

$$\frac{1}{\sin^2 \phi} \frac{d^2 \Theta}{d\theta^2} \Phi + \frac{\cos \phi}{\sin \phi} \frac{d\Phi}{d\phi} \Theta + \frac{d^2 \Phi}{d\phi^2} \Theta + k^2 \Theta \Phi = 0. \quad (2)$$

Dividing both sides by  $\Phi \Theta$ ,

$$\left( \frac{\cos \phi \sin \phi}{\Phi} \frac{d\Phi}{d\phi} + \frac{\sin^2 \phi}{\Phi} \frac{d^2 \Phi}{d\phi^2} \right) + \left( \frac{1}{\Theta} \frac{d^2 \Theta}{d\theta^2} + k^2 \right) = 0, \quad (3)$$

which can now be separated by writing

$$\frac{d^2 \Theta}{d\theta^2} \frac{1}{\Theta} = -(k^2 + m^2). \quad (4)$$

The solution to this equation must be periodic, so  $m$  must be an INTEGER. The solution may then be defined either as a COMPLEX function

$$\Theta(\theta) = A_m e^{i\sqrt{k^2+m^2}\theta} + B_m e^{-i\sqrt{k^2+m^2}\theta} \quad (5)$$

for  $m = -\infty, \dots, \infty$ , or as a sum of REAL sine and cosine functions

$$\Theta(\theta) = S_m \sin(\sqrt{k^2+m^2}\theta) + C_m \cos(\sqrt{k^2+m^2}\theta) \quad (6)$$

for  $m = 0, \dots, \infty$ . Plugging (4) into (3) gives

$$\frac{\cos \phi \sin \phi}{\Phi} \frac{d\Phi}{d\phi} + \frac{\sin^2 \phi}{\Phi} \frac{d^2 \Phi}{d\phi^2} + m^2 = 0 \quad (7)$$

$$\Phi'' + \frac{\cos \phi}{\sin \phi} \Phi' + \frac{m^2}{\sin^2 \phi} \Phi = 0, \quad (8)$$

which is the LEGENDRE DIFFERENTIAL EQUATION for  $x = \cos \phi$  with

$$m^2 \equiv l(l+1), \quad (9)$$

giving

$$l^2 + l - m^2 = 0 \quad (10)$$

$$l = \frac{1}{2}(-1 \pm \sqrt{1+4m^2}). \quad (11)$$

Solutions are therefore LEGENDRE POLYNOMIALS with a COMPLEX index. The general COMPLEX solution is then

$$F(\theta, \phi) = \sum_{m=-\infty}^{\infty} P_l(\cos \phi) (A_m e^{im\theta} + B_m e^{-im\theta}), \quad (12)$$

and the general REAL solution is

$$F(\theta, \phi) = \sum_{m=0}^{\infty} P_l(\cos \phi) [S_m \sin(m\theta) + C_m \cos(m\theta)]. \quad (13)$$

Note that these solutions depend on only a single variable  $m$ . However, on the surface of a sphere, it is usual to express solutions in terms of the SPHERICAL HARMONICS derived for the 3-D spherical case, which depend on the two variables  $l$  and  $m$ .

### Helmholtz Differential Equation—Toroidal Coordinates

The HELMHOLTZ DIFFERENTIAL EQUATION is not separable.

see LAPLACE'S EQUATION—TOROIDAL COORDINATES

**Helmholtz's Theorem**

Any VECTOR FIELD  $\mathbf{v}$  satisfying

$$[\nabla \cdot \mathbf{v}]_{\infty} = 0 \quad (1)$$

$$[\nabla \times \mathbf{v}]_{\infty} = 0 \quad (2)$$

may be written as the sum of an IRROTATIONAL part and a SOLENOIDAL part,

$$\mathbf{v} = -\nabla\phi + \nabla \times \mathbf{A}, \quad (3)$$

where for a VECTOR FIELD  $\mathbf{F}$ ,

$$\phi = - \int_V \frac{\nabla \cdot \mathbf{F}}{4\pi|\mathbf{r}' - \mathbf{r}|} d^3\mathbf{r}' \quad (4)$$

$$\mathbf{A} = \int_V \frac{\nabla \times \mathbf{F}}{4\pi|\mathbf{r}' - \mathbf{r}|} d^3\mathbf{r}'. \quad (5)$$

see also IRROTATIONAL FIELD, SOLENOIDAL FIELD, VECTOR FIELD

**Helson-Szegő Measure**

An absolutely continuous measure on  $\partial D$  whose density has the form  $\exp(x + \bar{y})$ , where  $x$  and  $y$  are real-valued functions in  $L^\infty$ ,  $\|y\|_\infty < \pi/2$ ,  $\exp$  is the EXPONENTIAL FUNCTION, and  $\|y\|$  is the NORM.

**Hemicylindrical Function**

A function  $S_n(z)$  which satisfies the RECURRENCE RELATION

$$S_{n-1}(z) - S_{n+1}(z) = 2S'_n(z)$$

together with

$$S_1(z) = -S'_0(z)$$

is called a hemicylindrical function.

**Hemisphere**

Half of a SPHERE cut by a PLANE passing through its CENTER. A hemisphere of RADIUS  $r$  can be given by the usual SPHERICAL COORDINATES

$$x = r \cos \theta \sin \phi \quad (1)$$

$$y = r \sin \theta \sin \phi \quad (2)$$

$$z = r \cos \phi, \quad (3)$$

where  $\theta \in [0, 2\pi)$  and  $\phi \in [0, \pi/2]$ . All CROSS-SECTIONS passing through the  $z$ -axis are SEMICIRCLES.

The VOLUME of the hemisphere is

$$V = \pi \int_0^r (r^2 - z^2) dz = \frac{2}{3} \pi r^3. \quad (4)$$

The weighted mean of  $z$  over the hemisphere is

$$\langle z \rangle = \pi \int_0^r z(r^2 - z^2) dz = \frac{1}{4} \pi r^2. \quad (5)$$

The CENTROID is then given by

$$\bar{z} = \frac{\langle z \rangle}{V} = \frac{3}{8} r \quad (6)$$

(Beyer 1987).

**References**

Beyer, W. H. (Ed.) *CRC Standard Mathematical Tables*, 28th ed. Boca Raton, FL: CRC Press, p. 133, 1987.

**Hemispherical Function**

The hemisphere function is defined as

$$H(x, y) = \begin{cases} \sqrt{a - x^2 - y^2} & \text{for } \sqrt{x^2 + y^2} \leq a \\ 0 & \text{for } \sqrt{x^2 + y^2} > a. \end{cases}$$

Watson (1966) defines a hemispherical function as a function  $S$  which satisfies the RECURRENCE RELATIONS

$$S_{n-1}(z) - S_{n+1}(z) = 2S_n'(z)$$

with

$$S_1(z) = -S_0'(z).$$

### Hendecagon

see UNDECAGON

### Henneberg's Minimal Surface

A double algebraic surface of 15th order and fifth class which can be given by parametric equations

$$x(u, v) = 2 \sinh u \cos v - \frac{2}{3} \sinh(3u) \cos(3v) \quad (1)$$

$$y(u, v) = 2 \sinh u \sin v - \frac{2}{3} \sinh(3u) \sin(3v) \quad (2)$$

$$z(u, v) = 2 \cosh(2u) \cos(2v). \quad (3)$$

It can also be obtained from the ENNEPER-WEIERSTRASS PARAMETERIZATION with

$$f = 2 - 2z^{-4} \quad (4)$$

$$g = z. \quad (5)$$

### Hénon Attractor

see HÉNON MAP

### Hénon-Heiles Equation

A nonlinear nonintegrable HAMILTONIAN SYSTEM with

$$\ddot{x} = -\frac{\partial V}{\partial x} \quad (1)$$

$$\ddot{y} = -\frac{\partial V}{\partial y}, \quad (2)$$

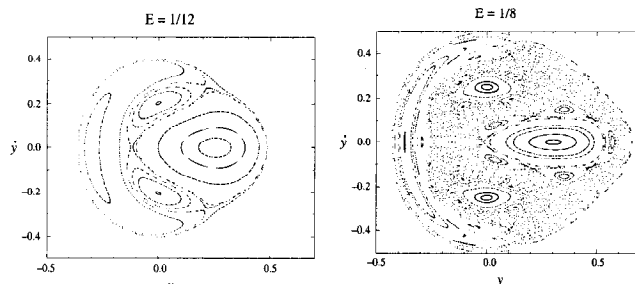

where

$$V(x, y) = \frac{1}{2}(x^2 + y^2 + 2x^2y - \frac{2}{3}y^3) \quad (3)$$

$$V(r, \theta) = \frac{1}{2}r^2 + \frac{1}{3}r^3 \sin(3\theta). \quad (4)$$

The energy is

$$E = V(x, y) + \frac{1}{2}(\dot{x}^2 + \dot{y}^2). \quad (5)$$

The above plots are SURFACES OF SECTION for  $E = 1/12$  and  $E = 1/8$ . The Hamiltonian for a generalized Hénon-Heiles potential is

$$H = \frac{1}{2}(p_x^2 + p_y^2 + Ax^2 + By^2) + Dx^2y - \frac{1}{3}Cy^3. \quad (6)$$

The equations of motion are integrable only for

1.  $D/C = 0$ ,
2.  $D/C = -1, A/B = 1$ ,
3.  $D/C = -1/6$ , and
4.  $D/C = -1/16, A/B = 1/6$ .

#### Hénon Map

A quadratic 2-D MAP given by the equations

$$x_{n+1} = 1 - \alpha x_n^2 + y_n \quad (1)$$

$$y_{n+1} = \beta x_n \quad (2)$$

or

$$x_{n+1} = x_n \cos \alpha - (y_n - x_n^2) \sin \alpha \quad (3)$$

$$y_{n+1} = x_n \sin \alpha + (y_n - x_n^2) \cos \alpha. \quad (4)$$

The above map is for  $\alpha = 1.4$  and  $\beta = 0.3$ . The Hénon map has CORRELATION EXPONENT  $1.25 \pm 0.02$  (Grassberger and Procaccia 1983) and CAPACITY DIMENSION  $1.261 \pm 0.003$  (Russell *et al.* 1980). Hitzl and Zele (1985) give conditions for the existence of periods 1 to 6.

#### Hensel's Lemma

An important result in VALUATION THEORY which gives information on finding roots of POLYNOMIALS. Hensel's lemma is formally stated as follow. Let  $(K, |\cdot|)$  be a complete non-Archimedean valuated field, and let  $R$  be the corresponding VALUATION RING. Let  $f(x)$  be a POLYNOMIAL whose COEFFICIENTS are in  $R$  and suppose  $a_0$  satisfies

$$|f(a_0)| < |f'(a_0)|^2, \quad (1)$$

where  $f'$  is the (formal) DERIVATIVE of  $f$ . Then there exists a unique element  $a \in R$  such that  $f(a) = 0$  and

$$|a - a_0| \leq \left| \frac{f(a_0)}{f'(a_0)} \right|. \quad (2)$$

Less formally, if  $f(x)$  is a POLYNOMIAL with "INTEGER" COEFFICIENTS and  $f(a_0)$  is "small" compared to  $f'(a_0)$ , then the equation  $f(x) = 0$  has a solution "near"  $a_0$ . In addition, there are no other solutions near  $a_0$ , although there may be other solutions. The proof of the LEMMA is based around the Newton-Raphson method and relies on the non-Archimedean nature of the valuation.

Consider the following example in which Hensel's lemma is used to determine that the equation  $x^2 = -1$  is solvable in the 5-adic numbers  $\mathbb{Q}_5$  (and so we can embed the GAUSSIAN INTEGERS inside  $\mathbb{Q}_5$  in a nice way). Let  $K$  be the 5-adic numbers  $\mathbb{Q}_5$ , let  $f(x) = x^2 + 1$ , and let  $a_0 = 2$ . Then we have  $f(2) = 5$  and  $f'(2) = 4$ , so

$$|f(2)|_5 = \frac{1}{5} < |f'(2)|_5^2 = 1, \quad (3)$$

and the condition is satisfied. Hensel's lemma then tells us that there is a 5-adic number  $a$  such that  $a^2 + 1 = 0$  and

$$|a - 2|_5 \leq \left| \frac{5}{4} \right|_5 = \frac{1}{5}. \quad (4)$$

Similarly, there is a 5-adic number  $b$  such that  $b^2 + 1 = 0$  and

$$|b - 3|_5 \leq \left| \frac{10}{7} \right|_5 = \frac{1}{5}. \quad (5)$$

Therefore, we have found both the square roots of  $-1$  in  $\mathbb{Q}_5$ . It is possible to find the roots of any POLYNOMIAL using this technique.

#### Henstock-Kurzweil Integral

see HK INTEGRAL

#### Heptacontagon

A 70-sided POLYGON.

## Heptadecagon

The REGULAR POLYGON of 17 sides is called the HEPTADECAGON, or sometimes the HEPTAKAIDECAGON. Gauss proved in 1796 (when he was 19 years old) that the heptadecagon is CONSTRUCTIBLE with a COMPASS and STRAIGHTEDGE. Gauss's proof appears in his monumental work *Disquisitiones Arithmeticae*. The proof relies on the property of irreducible POLYNOMIAL equations that ROOTS composed of a finite number of SQUARE ROOT extractions only exist when the order of the equation is a product of the form  $2^a 3^b F_c \cdot F_d \cdots F_e$ , where the  $F_n$  are distinct PRIMES of the form

$$F_n = 2^{2^n} + 1,$$

known as FERMAT PRIMES. Constructions for the regular TRIANGLE ( $3^1$ ), SQUARE ( $2^2$ ), PENTAGON ( $2^4 + 1$ ), HEXAGON ( $2^1 3^1$ ), etc., had been given by Euclid, but constructions based on the FERMAT PRIMES  $\geq 17$  were unknown to the ancients. The first explicit construction of a heptadecagon was given by Erchinger in about 1800.

17-gon

The following elegant construction for the heptadecagon (Yates 1949, Coxeter 1969, Stewart 1977, Wells 1992) was first given by Richmond (1893).

1. Given an arbitrary point  $O$ , draw a CIRCLE centered on  $O$  and a DIAMETER drawn through  $O$ .
2. Call the right end of the DIAMETER dividing the CIRCLE into a SEMICIRCLE  $P_0$ .
3. Construct the DIAMETER PERPENDICULAR to the original DIAMETER by finding the PERPENDICULAR BISECTOR  $OB$ .
4. Find  $J$  a QUARTER the way up  $OB$ .
5. Join  $JP_0$  and find  $E$  so that  $\angle OJE$  is a QUARTER of  $\angle OJP_0$ .
6. Find  $F$  so that  $\angle EJF$  is  $45^\circ$ .
7. Construct the SEMICIRCLE with DIAMETER  $FP_0$ .

8. This SEMICIRCLE cuts  $OB$  at  $K$ .
9. Draw a SEMICIRCLE with center  $E$  and RADIUS  $EK$ .
10. This cuts the extension of  $OP_0$  at  $N_3$ .
11. Construct a line PERPENDICULAR to  $OP_0$  through  $N_3$ .
12. This line meets the original SEMICIRCLE at  $P_3$ .
13. You now have points  $P_0$  and  $P_3$  of a heptadecagon.
14. Use  $P_0$  and  $P_3$  to get the remaining 15 points of the heptadecagon around the original CIRCLE by constructing  $P_0, P_3, P_6, P_9, P_{12}, P_{15}, P_1, P_4, P_7, P_{10}, P_{13}, P_{16}, P_2, P_5, P_8, P_{11}$ , and  $P_{14}$ .
15. Connect the adjacent points  $P_i$ .

This construction, when suitably streamlined, has SIMPLICITY 53. The construction of Smith (1920) has a greater SIMPLICITY of 58. Another construction due to Tietze (1965) and reproduced in Hall (1970) has a SIMPLICITY of 50. However, neither Tietze (1965) nor Hall (1970) provides a proof that this construction is correct. Both Richmond's and Tietze's constructions require extensive calculations to prove their validity. De Temple (1991) gives an elegant construction involving the CARLYLE CIRCLES which has GEOMETROGRAPHY symbol  $8S_1 + 4S_2 + 22C_1 + 11C_3$  and SIMPLICITY 45. The construction problem has now been automated to some extent (Bishop 1978).

## Heptagon

The unconstructible regular seven-sided POLYGON, illustrated above, has SCHLÄFLI SYMBOL {7}.

Although the regular heptagon is not a CONSTRUCTIBLE POLYGON, Dixon (1991) gives several close approximations. While the ANGLE subtended by a side is  $360^\circ/7 \approx 51.428571^\circ$ , Dixon gives constructions containing angles of  $2\sin^{-1}(\sqrt{3}/4) \approx 51.317812^\circ$ ,  $\tan^{-1}(5/4) \approx 51.340191^\circ$ , and  $30^\circ + \sin^{-1}((\sqrt{3}-1)/2) \approx 51.470701^\circ$ .

Madachy (1979) illustrates how to construct a heptagon by folding and knotting a strip of paper.

## Heptagonal Number

A FIGURATE NUMBER of the form  $n(5n-3)/2$ . The first few are 1, 7, 18, 34, 55, 81, 112, ... (Sloane's A000566). The GENERATING FUNCTION for the heptagonal numbers is

$$\frac{x(4x+1)}{(1-x)^3} = x + 7x^2 + 18x^3 + 34x^4 + \dots$$

### References

- Sloane, N. J. A. Sequence A000566/M4358 in "An On-Line Version of the Encyclopedia of Integer Sequences."

## Heptagonal Pyramidal Number

A PYRAMIDAL NUMBER of the form  $n(n+1)(5n-2)/6$ . The first few are 1, 8, 26, 60, 115, ... (Sloane's A002413). The GENERATING FUNCTION for the heptagonal pyramidal numbers is

$$\frac{x(4x+1)}{(x-1)^4} = x + 8x^2 + 26x^3 + 60x^4 + \dots$$

### References

## Heptahedron

The regular heptahedron is a one-sided surface made from four TRIANGLES and three QUADRILATERALS. It is topologically equivalent to the ROMAN SURFACE (Wells 1991). While all of the faces are regular and vertices equivalent, the heptahedron is self-intersecting and is therefore not considered an ARCHIMEDEAN SOLID. There are three semiregular heptahedra: the pentagonal and pentagrammic PRISMS, and a FACETED OCTAHEDRON (Holden 1991).

## Herbrand's Theorem

Let an ideal class be in  $\mathcal{A}$  if it contains an IDEAL whose  $l$ th power is PRINCIPAL. Let  $i$  be an ODD INTEGER  $1 \leq i \leq l$  and define  $j$  by  $i+j=1$ . Then  $\mathcal{A}_1 = \langle e \rangle$ . If  $i \geq 3$  and  $l \nmid B_j$ , then  $\mathcal{A}_i = \langle e \rangle$ .

**Hereditary Representation**

The representation of a number as a sum of powers of a BASE  $b$ , followed by expression of each of the exponents as a sum of powers of  $b$ , etc., until the process stops. For example, the hereditary representation of 266 in base 2 is

$$\begin{aligned} 266 &= 2^8 + 2^3 + 2 \\ &= 2^{2^{2+1}} + 2^{2+1} + 2. \end{aligned}$$

see also GOODSTEIN SEQUENCE

**Heredit**

A property of a SPACE which is also true of each of its SUBSPACES. Being "COUNTABLE" is hereditary, but having a given GENUS is not.

**Hermann's Formula**

The MACHIN-LIKE FORMULA

$$\frac{1}{4}\pi = 2 \tan^{-1}\left(\frac{1}{2}\right) - \tan^{-1}\left(\frac{1}{7}\right).$$

The other 2-term MACHIN-LIKE FORMULAS are EULER'S MACHIN-LIKE FORMULA, HUTTON'S FORMULA, and MACHIN'S FORMULA.

**Hermann Grid Illusion**

A regular 2-D arrangement of squares separated by vertical and horizontal "canals." Looking at the grid produces the illusion of gray spots in the white AREA between square VERTICES. The illusion was noted by Hermann (1870) while reading a book on sound by J. Tyndall.

**References**

Fineman, M. *The Nature of Visual Illusion*. New York: Dover, pp. 139–140, 1996.

**Hermann-Hering Illusion**

The illusion in view by staring at the small black dot for a half minute or so, then switching to the white dot. The black squares appear stationary when staring at the white dot, but a fainter grid of moving squares also appears to be present.

**Hermann-Mauguin Symbol**

A symbol used to represent the point and space groups (e.g.,  $2/m\bar{3}$ ). Some symbols have abbreviated form. The equivalence between Hermann-Mauguin symbols ("crystallographic symbol") and SCHÖNFLIES SYMBOLS for the POINT GROUPS is given by Cotton (1990).

**Hermit Point**

see ISOLATED POINT

**Hermite Constants**

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

The Hermite constant is defined for DIMENSION  $n$  as the value

$$\gamma_n = \frac{\sup_f \min_i f(x_1, x_2, \dots, x_n)}{[\text{discriminant}(f)]^{1/n}}$$

(Le Lionnais 1983). In other words, they are given by

$$\gamma_n = 4 \left( \frac{\delta_n}{V_n} \right)^{2/n},$$

where  $\delta_n$  is the maximum lattice PACKING DENSITY for HYPERSPHERE PACKING and  $V_n$  is the CONTENT of the  $n$ -HYPERSPHERE. The first few values of  $(\gamma_n)^n$  are 1,  $4/3$ , 2, 4, 8,  $64/3$ , 64, 256, .... Values for larger  $n$  are not known.

For sufficiently large  $n$ ,

$$\frac{1}{2\pi e} \leq \frac{\gamma_n}{n} \leq \frac{1.744\dots}{2\pi e}.$$

**Hermite Differential Equation**

$$\frac{d^2 y}{dx^2} - 2x \frac{dy}{dx} + \lambda y = 0. \quad (1)$$

This differential equation has an irregular singularity at  $\infty$ . It can be solved using the series method

$$\sum_{n=0}^{\infty} (n+2)(n+1)a_{n+2}x^n - \sum_{n=1}^{\infty} 2na_nx^n + \sum_{n=0}^{\infty} \lambda a_nx^n = 0 \quad (2)$$

$$(2a_2 + \lambda a_4) + \sum_{n=1}^{\infty} [(n+2)(n+1)a_{n+2} - 2na_n + \lambda a_n]x^n = 0. \quad (3)$$

Therefore,

$$a_2 = -\frac{\lambda a_0}{2} \quad (4)$$

and

$$a_{n+2} = \frac{2n - \lambda}{(n+2)(n+1)} a_n \quad (5)$$

for  $n = 1, 2, \dots$ . Since (4) is just a special case of (5),

$$a_{n+2} = \frac{2n - \lambda}{(n+2)(n+1)} a_n \quad (6)$$

for  $n = 0, 1, \dots$ . The linearly independent solutions are then

$$y_1 = a_0 \left[ 1 - \frac{\lambda}{2!} x^2 - \frac{(4-\lambda)\lambda}{4!} x^4 - \frac{(8-\lambda)(4-\lambda)\lambda}{6!} x^6 - \dots \right] \quad (7)$$

$$y_2 = a_1 \left[ x + \frac{(2-\lambda)}{3!} x^3 + \frac{(6-\lambda)(2-\lambda)}{5!} x^5 + \dots \right]. \quad (8)$$

If  $\lambda \equiv 4n = 0, 4, 8, \dots$ , then  $y_1$  terminates with the POWER  $x^\lambda$ , and  $y_1$  (normalized so that the COEFFICIENT of  $x^n$  is  $2^n$ ) is the regular solution to the equation, known as the HERMITE POLYNOMIAL. If  $\lambda \equiv 4n+2 = 2, 6, 10, \dots$ , then  $y_2$  terminates with the POWER  $x^\lambda$ , and  $y_2$  (normalized so that the COEFFICIENT of  $x^n$  is  $2^n$ ) is the regular solution to the equation, known as the HERMITE POLYNOMIAL.

If  $\lambda = 0$ , then Hermite's differential equation becomes

$$y'' - 2xy' = 0, \quad (9)$$

which is of the form  $P_2(x)y'' + P_1(x)y' = 0$  and so has solution

$$y = c_1 \int \frac{dx}{\exp\left(\int \frac{P_1}{P_2} dx\right)} + c_2$$

$$= c_1 \int \frac{dx}{\exp \int -2x dx} + c_2$$

$$= c_1 \int \frac{dx}{e^{-x^2}} + c_2 = c_1 \int e^{x^2} dx + c_2. \quad (10)$$

## Hermite-Gauss Quadrature

Also called HERMITE QUADRATURE. A GAUSSIAN QUADRATURE over the interval  $(-\infty, \infty)$  with WEIGHTING FUNCTION  $W(x) = e^{-x^2}$ . The ABSCISSAS for quadrature order  $n$  are given by the roots of the HERMITE POLYNOMIALS  $H_n(x)$ , which occur symmetrically about 0. The WEIGHTS are

$$w_i = -\frac{A_{n+1}\gamma_n}{A_n H'_n(x_i) H_{n+1}(x_i)} = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{H_{n-1}(x_i) H'_n(x_i)}, \quad (1)$$

where  $A_n$  is the COEFFICIENT of  $x^n$  in  $H_n(x)$ . For HERMITE POLYNOMIALS,

$$A_n = 2^n, \quad (2)$$

so

$$\frac{A_{n+1}}{A_n} = 2. \quad (3)$$

Additionally,

$$\gamma_n = \sqrt{\pi} 2^n n!, \quad (4)$$

so

$$w_i = -\frac{2^{n+1} n! \sqrt{\pi}}{H_{n+1}(x_i) H'_n(x_i)}$$

$$= \frac{2^n (n-1)! \sqrt{\pi}}{H_{n-1}(x_i) H'_n(x_i)}. \quad (5)$$

Using the RECURRENCE RELATION

$$H'_n(x) = 2nH_{n-1}(x) = 2xH_n(x) - H_{n+1}(x) \quad (6)$$

yields

$$H'_n(x_i) = 2nH_{n-1}(x_i) = -H_{n+1}(x_i) \quad (7)$$

and gives

$$w_i = \frac{2^{n+1} n! \sqrt{\pi}}{[H'_n(x_i)]^2} = \frac{2^{n+1} n! \sqrt{\pi}}{[H_{n+1}(x_i)]^2}. \quad (8)$$

The error term is

$$E = \frac{n! \sqrt{\pi}}{2^n (2n)!} f^{(2n)}(\xi). \quad (9)$$

Beyer (1987) gives a table of ABSCISSAS and weights up to  $n=12$ .

$n$	$x_i$	$w_i$
2	$\pm 0.707107$	0.886227
3	0	1.18164
	$\pm 1.22474$	0.295409
4	$\pm 0.524648$	0.804914
	$\pm 1.65068$	0.0813128
5	0	0.945309
	$\pm 0.958572$	0.393619
	$\pm 2.02018$	0.0199532

The ABCISSAS and weights can be computed analytically for small  $n$ .

$n$	$x_i$	$w_i$
2	$\pm \frac{1}{2}\sqrt{2}$	$\frac{1}{2}\sqrt{\pi}$
3	0	$\frac{2}{3}\sqrt{\pi}$
	$\pm \frac{1}{2}\sqrt{6}$	$\frac{1}{6}\sqrt{\pi}$
4	$\pm \sqrt{\frac{3-\sqrt{6}}{2}}$	$\frac{\sqrt{\pi}}{4(3-\sqrt{6})}$
	$\pm \sqrt{\frac{3+\sqrt{6}}{2}}$	$\frac{\sqrt{\pi}}{4(3+\sqrt{6})}$

## Hermite Interpolation

see HERMITE'S INTERPOLATING FUNDAMENTAL POLYNOMIAL

## Hermite's Interpolating Fundamental Polynomial

Let  $l(x)$  be an  $n$ th degree POLYNOMIAL with zeros at  $x_1, \dots, x_m$ . Then the fundamental POLYNOMIALS are

$$h_\nu^{(1)}(x) = \left[ 1 - \frac{l''(x_\nu)}{l'(x_\nu)} \right] [l_\nu(x)]^2 \quad (1)$$

and

$$h_\nu^{(2)}(x) = (x - x_\nu)[l_\nu(x)]^2. \quad (2)$$

They have the properties

$$h_\nu^{(1)}(x_\mu) = \delta_{\nu\mu} \quad (3)$$

$$h_\nu^{(1)'}(x_\mu) = 0 \quad (4)$$

$$h_\nu^{(2)}(x_\mu) = 0 \quad (5)$$

$$h_\nu^{(2)'}(x_\mu) = \delta_{\nu\mu}. \quad (6)$$

Now let  $f_1, \dots, f_n$  and  $f'_1, \dots, f'_n$  be values. Then the expansion

$$W_n(x) = \sum_{\nu=1}^n f_\nu h_\nu^{(1)}(x) + \sum_{\nu=1}^n f'_\nu h_\nu^{(2)}(x) \quad (7)$$

gives the unique HERMITE'S INTERPOLATING FUNDAMENTAL POLYNOMIAL for which

$$W_n(x_\nu) = f_\nu \quad (8)$$

$$W'_n(x_\nu) = f'_\nu. \quad (9)$$

If  $f'_\nu = 0$ , these are called STEP POLYNOMIALS. The fundamental POLYNOMIALS satisfy

$$h_1(x) + \dots + h_n(x) = 1 \quad (10)$$

and

$$\sum_{\nu=1}^n x_\nu h_\nu^{(1)}(x) + \sum_{\nu=1}^n h_\nu^{(2)}(x) = x. \quad (11)$$

Also,

$$\int_a^b h_\nu^{(1)}(x) d\alpha(x) = \lambda_\nu \quad (12)$$

$$\int_a^b h_\nu^{(1)}(x) d\alpha(x) = 0 \quad (13)$$

$$\int_a^b x h_\nu'(x) d\alpha(x) = 0 \quad (14)$$

$$\int_a^b h_\nu^{(2)}(x) d\alpha(x) = 0 \quad (15)$$

$$\int_a^b h_\nu^{(2)'} d\alpha(x) = \lambda_\nu \quad (16)$$

$$\int_a^b x h_\nu^{(2)'}(x) dx = \lambda_\nu x_\nu, \quad (17)$$

for  $\nu = 1, \dots, n$ .

## Hermite-Lindemann Theorem

The expression

$$A_1 e^{\alpha_1} + A_2 e^{\alpha_2} + A_3 e^{\alpha_3} + \dots,$$

in which the COEFFICIENTS  $A_i$  differ from zero and in which the exponents  $\alpha_i$  are ALGEBRAIC NUMBERS differing from each other, cannot equal zero.

see also ALGEBRAIC NUMBER, CONSTANT PROBLEM, INTEGER RELATION, LINDEMANN-WEIERSTRASS THEOREM

### References

Dörrie, H. "The Hermite-Lindemann Transcendence Theorem." §26 in *100 Great Problems of Elementary Mathematics: Their History and Solutions*. New York: Dover, pp. 128–137, 1965.

## Hermite Polynomial

A set of ORTHOGONAL POLYNOMIALS. The Hermite polynomials  $H_n(x)$  are illustrated above for  $x \in [0, 1]$  and  $n = 1, 2, \dots, 5$ .

The GENERATING FUNCTION for Hermite polynomials is

$$\exp(2xt - t^2) \equiv \sum_{n=0}^{\infty} \frac{H_n(x)t^n}{n!}. \quad (1)$$

Using a TAYLOR SERIES shows that,

$$\begin{aligned} H_n(x) &= \left[ \left( \frac{\partial}{\partial t} \right)^n \exp(2xt - t^2) \right]_{t=0} \\ &= \left[ e^{x^2} \left( \frac{\partial}{\partial t} \right)^n e^{-(x-t)^2} \right]_{t=0}. \end{aligned} \quad (2)$$

Since  $\partial f(x-t)/\partial t = -\partial f(x-t)/\partial x$ ,

$$\begin{aligned} H_n(x) &= (-1)^n e^{x^2} \left[ \left( \frac{\partial}{\partial x} \right)^n e^{-(x-t)^2} \right]_{t=0} \\ &= (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}. \end{aligned} \quad (3)$$

Now define operators

$$\tilde{O}_1 \equiv -e^{x^2} \frac{d}{dx} e^{-x^2} \quad (4)$$

$$\tilde{O}_2 \equiv e^{x^2/2} \left( x - \frac{d}{dx} \right) e^{-x^2/2}. \quad (5)$$

It follows that

$$\tilde{O}_1 f = -e^{x^2} \frac{d}{dx} [f e^{-x^2}] = 2xf - \frac{df}{dx} \quad (6)$$

$$\begin{aligned} \tilde{O}_2 f &= e^{x^2/2} \left( x - \frac{d}{dx} \right) [f e^{-x^2/2}] \\ &= xf + xf - \frac{df}{dx} = 2xf - \frac{df}{dx}, \end{aligned} \quad (7)$$

so

$$\tilde{O}_1 = \tilde{O}_2, \quad (8)$$

and

$$-e^{x^2} \frac{d}{dx} e^{-x^2} = e^{x^2/2} \left( x - \frac{d}{dx} \right) e^{-x^2/2}, \quad (9)$$

which means the following definitions are equivalent:

$$\exp(2xt - t^2) \equiv \sum_{n=0}^{\infty} \frac{H_n(x)t^n}{n!} \quad (10)$$

$$H_n(x) \equiv (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2} \quad (11)$$

$$H_n(x) \equiv e^{x^2/2} \left( x - \frac{d}{dx} \right)^n e^{-x^2/2}. \quad (12)$$

The Hermite POLYNOMIALS are related to the derivative of the ERROR FUNCTION by

$$H_n(z) = (-1)^2 \frac{\sqrt{\pi}}{2} e^{z^2} \frac{d^{n+1}}{dz^{n+1}} \operatorname{erf}(z). \quad (13)$$

They have a contour integral representation

$$H_n(x) = \frac{n!}{2\pi i} \int e^{-t^2+2tx} t^{-n-1} dt. \quad (14)$$

They are orthogonal in the range  $(-\infty, \infty)$  with respect to the WEIGHTING FUNCTION  $e^{-x^2}$

$$\int_{-\infty}^{\infty} H_n(x) H_m(x) e^{-x^2} dx = \delta_{mn} 2^n n! \sqrt{\pi}. \quad (15)$$

Define the associated functions

$$u_n(x) \equiv \sqrt{\frac{a}{\pi^{1/2} n! 2^n}} H_n(ax) e^{-a^2 x^2/2}. \quad (16)$$

These obey the orthogonality conditions

$$\int_{-\infty}^{\infty} u_n(x) \frac{du_m}{dx} dx = \begin{cases} a\sqrt{\frac{n+1}{2}} & m = n+1 \\ -a\sqrt{\frac{n}{2}} & m = n-1 \\ 0 & \text{otherwise} \end{cases} \quad (17)$$

$$\int_{-\infty}^{\infty} u_m(x) u_n(x) dx = \delta_{mn} \quad (18)$$

$$\int_{-\infty}^{\infty} u_m(x) x u_n(x) dx = \begin{cases} \frac{1}{a} \sqrt{\frac{n+1}{2}} & m = n+1 \\ \frac{1}{a} \sqrt{\frac{n}{2}} & m = n-1 \\ 0 & \text{otherwise} \end{cases} \quad (19)$$

$$\int_{-\infty}^{\infty} u_m(x) x^2 u_n(x) dx = \begin{cases} \frac{2n+1}{2a^2} & m = n \\ \frac{\sqrt{(n+1)(n+2)}}{2a^2} & m = n+2 \\ 0 & m \neq n \neq n \pm 2 \end{cases} \quad (20)$$

$$\int_{-\infty}^{\infty} e^{-x^2} H_\alpha H_\beta H_\gamma dx = \sqrt{\pi} \frac{2^s \alpha! \beta! \gamma!}{(s-\alpha)!(s-\beta)!(s-\gamma)!}, \quad (21)$$

if  $\alpha + \beta + \gamma = 2s$  is EVEN and  $s \geq \alpha$ ,  $s \geq \beta$ , and  $s \geq \gamma$ . Otherwise, the last integral is 0 (Szegő 1975, p. 390).

They also satisfy the RECURRENCE RELATIONS

$$H_{n+1} = 2xH_n(x) - 2nH_{n-1}(x) \quad (22)$$

$$H'_n(x) = 2nH_{n-1}(x). \quad (23)$$

The DISCRIMINANT is

$$D_n = 2^{3n(n-1)/2} \prod_{\nu=1}^n \nu^\nu \quad (24)$$

(Szegő 1975, p. 143).

An interesting identity is

$$\sum_{\nu=0}^n \binom{n}{\nu} H_\nu(x) H_{n-\nu}(y) = 2^{n/2} H_n[2^{-1/2}(x+y)]. \quad (25)$$

The first few POLYNOMIALS are

$$\begin{aligned}
 H_0(x) &= 1 \\
 H_1(x) &= 2x \\
 H_2(x) &= 4x^2 - 2 \\
 H_3(x) &= 8x^3 - 12x \\
 H_4(x) &= 16x^4 - 48x^2 + 12 \\
 H_5(x) &= 32x^5 - 160x^3 + 120x \\
 H_6(x) &= 64x^6 - 480x^4 + 720x^2 - 120 \\
 H_7(x) &= 128x^7 - 1344x^5 + 3360x^3 - 1680x \\
 H_8(x) &= 256x^8 - 3594x^6 + 13440x^4 - 13440x^2 \\
 &\quad + 160 \\
 H_9(x) &= 512x^9 - 9216x^7 + 48384x^5 - 80640x^3 \\
 &\quad + 30240x \\
 H_{10}(x) &= 1024x^{10} - 23040x^8 + 161280x^6 - 403200x^4 \\
 &\quad + 302400x^2 - 30240.
 \end{aligned}$$

A class of generalized Hermite POLYNOMIALS  $\gamma_n^m(x)$  satisfying

$$e^{mx-t^m} = \sum_{n=0}^{\infty} \gamma_n^m(x) t^n \quad (26)$$

was studied by Subramanyan (1990). A class of related POLYNOMIALS defined by

$$h_{n,m} = \gamma_n^m \left( \frac{2x}{m} \right) \quad (27)$$

and with GENERATING FUNCTION

$$e^{2xt-t^m} = \sum_{n=0}^{\infty} h_{n,m}(x) t^n \quad (28)$$

was studied by Djordjević (1996). They satisfy

$$H_n(x) = n! h_{n,2}(x). \quad (29)$$

A modified version of the HERMITE POLYNOMIAL is sometimes defined by

$$\text{He}_n(x) \equiv H_n \left( \frac{x}{\sqrt{2}} \right). \quad (30)$$

see also MEHLER'S HERMITE POLYNOMIAL FORMULA, WEBER FUNCTIONS

#### Hermite Quadrature

see HERMITE-GAUSS QUADRATURE

#### Hermite's Theorem

$e$  is TRANSCENDENTAL.

#### Hermitian Form

A combination of variables  $x$  and  $y$  given by

$$axx^* + bxy^* + b^*x^*y + cyy^*,$$

where  $x^*$  and  $y^*$  are COMPLEX CONJUGATES.

#### Hermitian Matrix

If a MATRIX is SELF-ADJOINT, it is said to be a Hermitian matrix. Therefore, a Hermitian MATRIX is defined as one for which

$$\mathbf{A} = \mathbf{A}^\dagger, \quad (1)$$

where  $\dagger$  denotes the ADJOINT MATRIX. Hermitian MATRICES have REAL EIGENVALUES with ORTHOGONAL EIGENVECTORS. For REAL MATRICES, Hermitian is the same as symmetrical. Any MATRIX  $\mathbf{C}$  which is not Hermitian can be expressed as the sum of two Hermitian matrices

$$\mathbf{C} = \frac{1}{2}(\mathbf{C} + \mathbf{C}^\dagger) + \frac{1}{2}(\mathbf{C} - \mathbf{C}^\dagger). \quad (2)$$

Let  $\mathbf{U}$  be a UNITARY MATRIX and  $\mathbf{A}$  be a Hermitian matrix. Then the ADJOINT MATRIX of a SIMILARITY TRANSFORMATION is

$$\begin{aligned}
 (\mathbf{U}\mathbf{A}\mathbf{U}^{-1})^\dagger &= [(\mathbf{U}\mathbf{A})(\mathbf{U}^{-1})]^\dagger = (\mathbf{U}^{-1})^\dagger(\mathbf{U}\mathbf{A})^\dagger \\
 &= (\mathbf{U}^\dagger)^\dagger(\mathbf{A}^\dagger\mathbf{U}^\dagger) = \mathbf{U}\mathbf{A}\mathbf{U}^\dagger = \mathbf{U}\mathbf{A}\mathbf{U}^{-1}. \quad (3)
 \end{aligned}$$

The specific matrix

$$H(x, y, z) = \begin{bmatrix} z & x + iy \\ x - iy & -z \end{bmatrix} = xP_1 + yP_2 + zP_3, \quad (4)$$

where  $P_i$  are PAULI SPIN MATRICES, is sometimes called "the" Hermitian matrix.

see also ADJOINT MATRIX, HERMITIAN OPERATOR, PAULI SPIN MATRICES

Arfken, G. "Hermitian Matrices, Unitary Matrices." §4.5 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 209–217, 1985.

#### Hermitian Operator

A Hermitian OPERATOR  $\tilde{L}$  is one which satisfies

$$\int_a^b v^* \tilde{L}u \, dx = \int_a^b u \tilde{L}v^* \, dx. \quad (1)$$

As shown in STURM-LIOUVILLE THEORY, if  $\tilde{L}$  is SELF-ADJOINT and satisfies the boundary conditions

$$[v^* pu']_{x=a} = [v^* pu']_{x=b}, \quad (2)$$

then it is automatically Hermitian. Hermitian operators have REAL EIGENVALUES, ORTHOGONAL EIGENFUNCTIONS, and the corresponding EIGENFUNCTIONS form a COMPLETE set when  $\tilde{L}$  is second-order and linear. In order to prove that EIGENVALUES must be REAL and EIGENFUNCTIONS ORTHOGONAL, consider

$$\tilde{L}u_i + \lambda_i wu_i = 0. \quad (3)$$

Assume there is a second EIGENVALUE  $\lambda_j$  such that

$$\tilde{L}u_j + \lambda_j wu_j = 0 \quad (4)$$

$$\tilde{L}u_j^* + \lambda_j^* wu_j^* = 0. \quad (5)$$

Now multiply (3) by  $u_j^*$  and (5) by  $u_i$

$$u_j^* \tilde{L}u_i + u_j^* \lambda_i wu_i = 0 \quad (6)$$

$$u_i \tilde{L}u_j^* + u_i \lambda_j^* wu_j^* = 0 \quad (7)$$

$$u_j^* \tilde{L}u_i - u_i \tilde{L}u_j^* = (\lambda_j^* - \lambda_i) wu_i u_j^*. \quad (8)$$

Now integrate

$$\int_a^b u_j^* \tilde{L}u_i - \int_a^b u_i \tilde{L}u_j^* = (\lambda_j^* - \lambda_i) \int_a^b wu_i u_j^*. \quad (9)$$

But because  $\tilde{L}$  is Hermitian, the left side vanishes.

$$(\lambda_j^* - \lambda_i) \int_a^b wu_i u_j^* = 0. \quad (10)$$

If EIGENVALUES  $\lambda_i$  and  $\lambda_j$  are not degenerate, then  $\int_a^b wu_i u_j^* = 0$ , so the EIGENFUNCTIONS are ORTHOGONAL. If the EIGENVALUES are degenerate, the EIGENFUNCTIONS are not necessarily orthogonal. Now take  $i = j$ .

$$(\lambda_i^* - \lambda_i) \int_a^b wu_i u_i^* = 0. \quad (11)$$

The integral cannot vanish unless  $u_i = 0$ , so we have  $\lambda_i^* = \lambda_i$  and the EIGENVALUES are real.

For a Hermitian operator  $\tilde{O}$ ,

$$\langle \phi | \tilde{O} \psi \rangle = \langle \phi | \tilde{O} \psi \rangle^* = \langle \tilde{O} \phi | \psi \rangle. \quad (12)$$

In integral notation,

$$\int (\tilde{A}\phi)^* \psi \, dx = \int \phi^* \tilde{A}\psi \, dx. \quad (13)$$

Given Hermitian operators  $\tilde{A}$  and  $\tilde{B}$ ,

$$\langle \phi | \tilde{A} \tilde{B} \psi \rangle = \langle \tilde{A} \phi | \tilde{B} \psi \rangle = \langle \tilde{B} \tilde{A} \phi | \psi \rangle = \langle \phi | \tilde{B} \tilde{A} \psi \rangle^*. \quad (14)$$

Because, for a Hermitian operator  $\tilde{A}$  with EIGENVALUE  $a$ ,

$$\langle \psi | \tilde{A} \psi \rangle = \langle \tilde{A} \psi | \psi \rangle \quad (15)$$

$$a \langle \psi | \psi \rangle = a^* \langle \psi | \psi \rangle. \quad (16)$$

Therefore, either  $\langle \psi | \psi \rangle = 0$  or  $a = a^*$ . But  $\langle \psi | \psi \rangle = 0$  IFF  $\psi = 0$ , so

$$\langle \psi | \psi \rangle \neq 0, \quad (17)$$

for a nontrivial EIGENFUNCTION. This means that  $a = a^*$ , namely that Hermitian operators produce REAL expectation values. Every observable must therefore have a corresponding Hermitian operator. Furthermore,

$$\langle \psi_n | \tilde{A} \psi_m \rangle = \langle \tilde{A} \psi_n | \psi_m \rangle \quad (18)$$

$$a_m \langle \psi_n | \psi_m \rangle = a_n^* \langle \psi_n | \psi_m \rangle = a_n \langle \psi_n | \psi_m \rangle, \quad (19)$$

since  $a_n = a_n^*$ . Then

$$(a_m - a_n) \langle \psi_n | \psi_m \rangle = 0 \quad (20)$$

For  $a_m \neq a_n$  (i.e.,  $\psi_n \neq \psi_m$ ),

$$\langle \psi_n | \psi_m \rangle = 0. \quad (21)$$

For  $a_m = a_n$  (i.e.,  $\psi_n = \psi_m$ ),

$$\langle \psi_n | \psi_m \rangle = \langle \psi_n | \psi_n \rangle \equiv 1. \quad (22)$$

Therefore,

$$\langle \psi_n | \psi_m \rangle = \delta_{nm}, \quad (23)$$

so the basis of EIGENFUNCTIONS corresponding to a Hermitian operator are ORTHONORMAL. Given two Hermitian operators  $\tilde{A}$  and  $\tilde{B}$ ,

$$(\tilde{A}\tilde{B})^\dagger = \tilde{B}^\dagger\tilde{A}^\dagger = \tilde{B}\tilde{A} = \tilde{A}\tilde{B} + [\tilde{B}, \tilde{A}], \quad (24)$$

the operator  $\tilde{A}\tilde{B}$  equals  $(\tilde{A}\tilde{B})^\dagger$ , and is therefore Hermitian, only if

$$[\tilde{B}, \tilde{A}] = 0. \quad (25)$$

Given an arbitrary operator  $\tilde{A}$ ,

$$\begin{aligned} \langle \psi_1 | (\tilde{A} + \tilde{A}^\dagger) \psi_2 \rangle &= \langle (\tilde{A}^\dagger + \tilde{A}) \psi_1 | \psi_2 \rangle \\ &= \langle (\tilde{A} + \tilde{A}^\dagger) \psi_1 | \psi_2 \rangle, \end{aligned} \quad (26)$$

so  $\tilde{A} + \tilde{A}^\dagger$  is Hermitian.

$$\begin{aligned} \langle \psi_1 | i(\tilde{A} - \tilde{A}^\dagger) \psi_2 \rangle &= \langle -i(\tilde{A}^\dagger - \tilde{A}) \psi_1 | \psi_2 \rangle \\ &= \langle i(\tilde{A} - \tilde{A}^\dagger) \psi_1 | \psi_2 \rangle, \end{aligned} \quad (27)$$

so  $i(\tilde{A} - \tilde{A}^\dagger)$  is Hermitian. Similarly,

$$\langle \psi_1 | (\tilde{A}\tilde{A}^\dagger) \psi_2 \rangle = \langle \tilde{A}^\dagger \psi_1 | \tilde{A}^\dagger \psi_2 \rangle = \langle (\tilde{A}\tilde{A}^\dagger) \psi_1 | \psi_2 \rangle, \quad (28)$$

so  $\tilde{A}\tilde{A}^\dagger$  is Hermitian.

Define the Hermitian conjugate operator  $\tilde{A}^\dagger$  by

$$\langle \tilde{A}\psi | \psi \rangle \equiv \langle \psi | \tilde{A}^\dagger \psi \rangle. \quad (29)$$

For a Hermitian operator,  $\tilde{A} = \tilde{A}^\dagger$ . Furthermore, given two Hermitian operators  $\tilde{A}$  and  $\tilde{B}$ ,

$$\begin{aligned} \langle \psi_2 | (\tilde{A}\tilde{B})^\dagger \psi_1 \rangle &= \langle (\tilde{A}\tilde{B}) \psi_2 | \psi_1 \rangle = \langle \tilde{B} \psi_2 | \tilde{A}^\dagger \psi_1 \rangle \\ &= \langle \psi_2 | \tilde{B}^\dagger \tilde{A}^\dagger \psi_1 \rangle, \end{aligned} \quad (30)$$

so

$$(\tilde{A}\tilde{B})^\dagger = \tilde{B}^\dagger \tilde{A}^\dagger. \quad (31)$$

By further iterations, this can be generalized to

$$(\tilde{A}\tilde{B} \dots \tilde{Z})^\dagger = \tilde{Z}^\dagger \dots \tilde{B}^\dagger \tilde{A}^\dagger. \quad (32)$$

#### Heron's Formula

Gives the AREA of a TRIANGLE in terms of the lengths of the sides  $a$ ,  $b$ , and  $c$  and the SEMIPERIMETER

$$s \equiv \frac{1}{2}(a + b + c). \quad (1)$$

Heron's formula then states

$$\Delta = \sqrt{s(s-a)(s-b)(s-c)}. \quad (2)$$

Expressing the side lengths  $a$ ,  $b$ , and  $c$  in terms of the radii  $a'$ ,  $b'$ , and  $c'$  of the mutually tangent circles centered on the TRIANGLE vertices (which define the SODDY CIRCLES),

$$a = b' + c' \quad (3)$$

$$b = a' + c' \quad (4)$$

$$c = a' + b', \quad (5)$$

gives the particularly pretty form

$$\Delta = \sqrt{a'b'c'(a' + b' + c')} \quad (6)$$

The proof of this fact was discovered by Heron (ca. 100 BC-100 AD), although it was already known to Archimedes prior to 212 BC (Kline 1972). Heron's proof (Dunham 1990) is ingenious but extremely convoluted, bringing together a sequence of apparently unrelated geometric identities and relying on the properties of CYCLIC QUADRILATERALS and RIGHT TRIANGLES.

Heron's proof can be found in Proposition 1.8 of his work *Metrica*. This manuscript had been lost for centuries until a fragment was discovered in 1894 and a complete copy in 1896 (Dunham 1990, p. 118). More recently, writings of the Arab scholar Abu'l Raihan Muhammed al-Biruni have credited the formula to Heron's predecessor Archimedes (Dunham 1990, p. 127).

A much more accessible algebraic proof proceeds from the LAW OF COSINES,

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}. \quad (7)$$

Then

$$\sin A = \frac{\sqrt{-a^4 - b^4 - c^4 + 2b^2c^2 + 2c^2a^2 + 2a^2b^2}}{2bc}, \quad (8)$$

giving

$$\Delta = \frac{1}{2}bc \sin A \quad (9)$$

$$= \frac{1}{4} \sqrt{-a^4 - b^4 - c^4 + 2b^2c^2 + 2c^2a^2 + 2a^2b^2} \quad (10)$$

$$= \frac{1}{4} [(a+b+c)(-a+b+c)(a-b+c)(a+b-c)]^{1/2} \quad (11)$$

$$= \sqrt{s(s-a)(s-b)(s-c)} \quad (12)$$

(Coxeter 1969). Heron's formula contains the PYTHAGOREAN THEOREM.

## Heronian Triangle

A TRIANGLE with RATIONAL side lengths and RATIONAL AREA. Brahmagupta gave a parametric solution for integer Heronian triangles (the three side lengths and area can be multiplied by their LEAST COMMON MULTIPLE to make them all INTEGERS): side lengths  $c(a^2 + b^2)$ ,  $b(a^2 + c^2)$ , and  $(b + c)(a^2 - bc)$ , giving SEMIPERIMETER

$$s = a^2(b + c)$$

and AREA

$$\Delta = abc(a + b)(a^2 - bc).$$

The first few integer Heronian triangles, sorted by increasing maximal side lengths, are (3, 4, 5), (6, 8, 10), (5, 12, 13), (9, 12, 15), (4, 13, 15), (13, 14, 15), (9, 10, 17), ... (Sloane's A046128, A046129, and A046130), having areas 6, 24, 30, 54, 24, 84, 36, ... (Sloane's A046131).

Schubert (1905) claimed that Heronian triangles with two rational MEDIANS do not exist (Dickson 1952). This was shown to be incorrect by Buchholz and Rathbun (1997), who discovered six such triangles.

3	4	5	9	10	11	12
			13	14	16	15

A heterosquare is an  $n \times n$  ARRAY of the integers from 1 to  $n^2$  such that the rows, columns, and diagonals have different sums. (By contrast, in a MAGIC SQUARE, they have the *same* sum.) There are no heterosquares of order two, but heterosquares of every ODD order exist. They can be constructed by placing consecutive INTEGERS in a SPIRAL pattern (Fults 1974, Madachy 1979).

An ANTIMAGIC SQUARE is a special case of a heterosquare for which the sums of rows, columns, and main diagonals form a SEQUENCE of consecutive integers.

**Hex Number**

The CENTERED HEXAGONAL NUMBER given by

$$H_n = 1 + 6T_n = 2H_{n-1} - H_{n-2} + 6 = 3n^2 - 3n + 1,$$

where  $T_n$  is the  $n$ th TRIANGULAR NUMBER. The first few hex numbers are 1, 7, 19, 37, 61, 91, 127, 169, ... (Sloane's A003215). The GENERATING FUNCTION of the hex numbers is

$$\frac{x(x^2 + 4x + 1)}{(1 - x)^3} = x + 7x^2 + 19x^3 + 37x^4 + \dots$$

The first TRIANGULAR hex numbers are 1 and 91, and the first few SQUARE ones are 1, 169, 32761, 6355441, ... (Sloane's A006051). SQUARE hex numbers are obtained by solving the DIOPHANTINE EQUATION

$$3x^2 + 1 = y^2.$$

The only hex number which is SQUARE and TRIANGULAR is 1. There are no CUBIC hex numbers.

### Hexagon

A six-sided POLYGON. In proposition IV.15, Euclid showed how to inscribe a regular hexagon in a CIRCLE. The INRADIUS  $r$ , CIRCUMRADIUS  $R$ , and AREA  $A$  can be computed directly from the formulas for a general regular POLYGON with side length  $s$  and  $n = 6$  sides,

$$r = \frac{1}{2}s \cot\left(\frac{\pi}{6}\right) = \frac{1}{2}\sqrt{3}s \quad (1)$$

$$R = \frac{1}{2}s \csc\left(\frac{\pi}{6}\right) = s \quad (2)$$

$$A = \frac{1}{4}ns^2 \cot\left(\frac{\pi}{6}\right) = \frac{3}{2}\sqrt{3}s^2. \quad (3)$$

Therefore, for a regular hexagon,

$$\frac{R}{r} = \sec\left(\frac{\pi}{6}\right) = \frac{2}{\sqrt{3}}, \quad (4)$$

so

$$\frac{A_R}{A_r} = \left(\frac{R}{r}\right)^2 = \frac{4}{3}. \quad (5)$$

A PLANE PERPENDICULAR to a  $C_3$  axis of a CUBE, DODECAHEDRON, or ICOSAHEDRON cuts the solid in a regular HEXAGONAL CROSS-SECTION (Holden 1991, pp. 22–23 and 27). For the CUBE, the PLANE passes through the MIDPOINTS of opposite sides (Steinhaus 1983, p. 170; Cundy and Rollett 1989, p. 157; Holden 1991, pp. 22–23). Since there are four such axes for the CUBE and OCTAHEDRON, there are four possibly hexagonal cross-sections. Since there are four such axes in each case, there are also four possibly hexagonal cross-sections.

Take seven CIRCLES and close-pack them together in a hexagonal arrangement. The PERIMETER obtained by wrapping a band around the CIRCLE then consists of six straight segments of length  $d$  (where  $d$  is the DIAMETER) and 6 arcs with total length  $1/6$  of a CIRCLE. The PERIMETER is therefore

$$p = (12 + 2\pi)r = 2(6 + \pi)r. \quad (6)$$

## Hexagonal Number

A FIGURATE NUMBER and 6-POLYGONAL NUMBER of the form  $n(2n - 1)$ . The first few are 1, 6, 15, 28, 45, ... (Sloane's A000384). The GENERATING FUNCTION of the hexagonal numbers

$$\frac{x(3x + 1)}{(1 - x)^3} = x + 6x^2 + 15x^3 + 28x^4 + \dots$$

Every hexagonal number is a TRIANGULAR NUMBER since

$$r(2r - 1) = \frac{1}{2}(2r - 1)[(2r - 1) + 1].$$

In 1830, Legendre (1979) proved that every number larger than 1791 is a sum of four hexagonal numbers, and Duke and Schulze-Pillot (1990) improved this to three hexagonal numbers for every sufficiently large integer. The numbers 11 and 26 can only be represented as a sum using the maximum possible of six hexagonal numbers:

$$11 = 1 + 1 + 1 + 1 + 1 + 6$$

$$26 = 1 + 1 + 6 + 6 + 6 + 6.$$

**Hexlet**

Also called SODDY'S HEXLET. Consider three mutually tangent SPHERES  $A$ ,  $B$ , and  $C$ . Then construct a chain of SPHERES tangent to each of  $A$ ,  $B$ , and  $C$  threading and interlocking with the  $A - B - C$  ring. Surprisingly, every chain closes into a "necklace" after six SPHERES regardless of where the first SPHERE is placed. This is a special case of KOLLROS' THEOREM. The centers of a Soddy hexlet always lie on an ELLIPSE (Ogilvy 1990, p. 63).

**Hh Function**

Let

$$Z(x) \equiv \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \quad (1)$$

$$Q(x) \equiv \frac{1}{\sqrt{2\pi}} \int_x^\infty e^{-t^2/2} dt, \quad (2)$$

where  $Z$  and  $Q$  are closely related to the NORMAL DISTRIBUTION FUNCTION, then

$$\text{Hh}_{-n}(x) = (-1)^{n-1} \sqrt{2\pi} z^{(n-1)}(x) \quad (3)$$

$$\text{Hh}_n(x) = \frac{(-1)^n}{n!} \text{Hh}_{-1}(x) \frac{d^n}{dx^n} \left[ \frac{Q(x)}{Z(x)} \right]. \quad (4)$$

see also NORMAL DISTRIBUTION FUNCTION, TETRACHORIC FUNCTION

**Hhi-Q**

A triangular version of PEG SOLITAIRE with 15 holes and 14 pegs. Numbering hole 1 at the apex of the triangle and thereafter from left to right on the next lower row, etc., the following table gives possible ending holes for a single peg removed (Beeler *et al.* 1972, Item 76). Because of symmetry, only the first five pegs need be considered. Also because of symmetry, removing peg 2 is equivalent to removing peg 3 and flipping the board horizontally.

remove	possible ending pegs
1	1, 7 = 10, 13
2	2, 6, 11, 14
4	3 = 12, 4, 9, 15
5	13

**HighLife**

An alternate set of LIFE rules similar to Conway's, but with the additional rule that six neighbors generate a birth. Most of the interest in this variant is due to the presence of a so-called replicator.

see also HEXLIFE, LIFE

**References**

- Hensel, A. "A Brief Illustrated Glossary of Terms in Conway's Game of Life." <http://www.cs.jhu.edu/~callahan/glossary.html>.

**Highly Abundant Number**

see HIGHLY COMPOSITE NUMBER

**Highly Composite Number**

A COMPOSITE NUMBER (also called a SUPERABUNDANT NUMBER) is a number  $n$  which has more FACTORS than any other number less than  $n$ . In other words,  $\sigma(n)/n$  exceeds  $\sigma(k)/k$  for all  $k < n$ , where  $\sigma(n)$  is the DIVISOR FUNCTION. They were called highly composite numbers by Ramanujan, who found the first 100 or so, and superabundant by Alaoglu and Erdős (1944).

There are an infinite numbers of highly composite numbers, and the first few are 2, 4, 6, 12, 24, 36, 48, 60, 120, 180, 240, 360, 720, 840, 1260, 1680, 2520, 5040, ... (Sloane's A002182). Ramanujan (1915) listed 102 up to 6746328388800 (but omitted 293, 318, 625, 600, and 29331862500). Robin (1983) gives the first 5000 highly composite numbers, and a comprehensive survey is given by Nicholas (1988).

If

$$N = 2^{a_2} 3^{a_3} \dots p^{a_p} \quad (1)$$

is the prime decomposition of a highly composite number, then

1. The PRIMES 2, 3, ...,  $p$  form a string of consecutive PRIMES,
2. The exponents are nonincreasing, so  $a_2 \geq a_3 \geq \dots \geq a_p$ , and
3. The final exponent  $a_p$  is always 1, except for the two cases  $N = 4 = 2^2$  and  $N = 36 = 2^2 \cdot 3^2$ , where it is 2.

Let  $Q(x)$  be the number of highly composite numbers  $\leq x$ . Ramanujan (1915) showed that

$$\lim_{x \rightarrow \infty} \frac{Q(x)}{\ln x} = \infty. \quad (2)$$

Erdős (1944) showed that there exists a constant  $c_1 > 0$  such that

$$Q(x) \geq (\ln x)^{1+c_1} \quad (3)$$

Nicholas proved that there exists a constant  $c_2 > 0$  such that

$$Q(x) \ll (\ln x)^{c_2}. \quad (4)$$

### Hilbert's Constants

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

Extend HILBERT'S INEQUALITY by letting  $p, q > 1$  and

$$\frac{1}{p} + \frac{1}{q} \geq 1, \quad (1)$$

so that

$$0 < \lambda = 2 - \frac{1}{p} - \frac{1}{q} \leq 1. \quad (2)$$

Levin (1937) and Stečkin (1949) showed that

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{a_m b_n}{(m+n)^{\lambda}} \leq \left\{ \pi \csc \left[ \frac{\pi(q-1)}{\lambda q} \right] \right\}^{\lambda} \times \left( \int_0^{\infty} [f(x)]^p dx \right)^{1/p} \left( \int_0^{\infty} [g(x)]^q dx \right)^{1/q} \quad (3)$$

and

$$\int_0^{\infty} \int_0^{\infty} \frac{f(x)g(y)}{(x+y)^{\lambda}} dx dy < \pi \csc \left[ \frac{\pi(q-1)}{p} \right]^{\lambda} \times \left( \int_0^{\infty} [f(x)]^p dx \right)^{1/p} \left( \int_0^{\infty} [g(x)]^q dx \right)^{1/q}. \quad (4)$$

Mitrinovic *et al.* (1991) indicate that this constant is the best possible.

### Hilbert Curve

A LINDENMAYER SYSTEM invented by Hilbert (1891) whose limit is a PLANE-FILLING CURVE which fills a square. Traversing the VERTICES of an  $n$ -D HYPERCUBE in GRAY CODE order produces a generator for the  $n$ -D Hilbert curve (Goetz). The Hilbert curve can be simply encoded with initial string "L", STRING REWRITING rules "L"  $\rightarrow$  "+RF-LFL-FR+", "R"  $\rightarrow$  "-LF+RFR+FL-", and angle  $90^\circ$  (Peitgen and Saupe 1988, p. 278).

A related curve is the Hilbert II curve, shown above (Peitgen and Saupe 1988, p. 284). It is also a LINDENMAYER SYSTEM and the curve can be encoded with initial string "X", STRING REWRITING rules "X"  $\rightarrow$  "XFYFX+F+YFXFY-F-XFYFX", "Y"  $\rightarrow$  "YFXFY-F-XFYFX+F+YFXFY", and angle  $90^\circ$ .

### Hilbert Function

Let  $\Gamma = \{p_1, \dots, p_m\} \subset \mathbb{P}^2$  be a collection of  $m$  distinct points. Then the number of conditions imposed by  $\Gamma$  on forms of degree  $d$  is called the Hilbert function  $h_\Gamma$  of  $\Gamma$ . If curves  $X_1$  and  $X_2$  of degrees  $d$  and  $e$  meet in a collection  $\Gamma$  of  $d \cdot e$  points, then for any  $k$ , the number  $h_\Gamma(k)$  of conditions imposed by  $\Gamma$  on forms of degree  $k$  is independent of  $X_1$  and  $X_2$  and is given by

$$h_\Gamma(k) = \binom{k+2}{2} - \binom{k-d+2}{2} - \binom{k-e+2}{2} + \binom{k-d-e+2}{2},$$

where the BINOMIAL COEFFICIENT  $\binom{a}{2}$  is taken as 0 if  $a < 2$  (Cayley 1843).

### Hilbert Hotel

Let a hotel have a DENUMERABLE set of rooms numbered 1, 2, 3, .... Then any finite number  $n$  of guests can be accommodated without evicting the current guests by moving the current guests from room  $i$  to room  $i + n$ . Furthermore, a DENUMERABLE number

of guests can be similarly accommodated by moving the existing guests from  $i$  to  $2i$ , freeing up a DENUMERABLE number of rooms  $2i - 1$ .

### Hilbert's Inequality

Given a POSITIVE SEQUENCE  $\{a_n\}$ ,

$$\sqrt{\sum_{j=-\infty}^{\infty} \left| \sum_{\substack{n=-\infty \\ n \neq j}}^{\infty} \frac{a_n}{j-n} \right|^2} \leq \pi \sqrt{\sum_{n=-\infty}^{\infty} |a_n|^2},$$

where the  $a_n$ s are REAL and "square summable."

Another INEQUALITY known as Hilbert's applies to NONNEGATIVE sequences  $\{a_n\}$  and  $\{b_n\}$ ,

$$\sum_{m=1}^{\infty} \sum_{n=1}^{\infty} \frac{a_m b_n}{m+n} < \pi \csc\left(\frac{\pi}{p}\right) \left(\sum_{m=1}^{\infty} a_m^p\right)^{1/p} \left(\sum_{n=1}^{\infty} b_n^q\right)^{1/q}$$

unless all  $a_n$  or all  $b_n$  are 0. If  $f(x)$  and  $g(x)$  are NON-NEGATIVE integrable functions, then the integral form is

$$\int_0^{\infty} \int_0^{\infty} \frac{f(x)g(y)}{x+y} dx dy < \pi \csc\left(\frac{\pi}{p}\right) \times \left(\int_0^{\infty} [f(x)]^p dx\right)^{1/p} \left(\int_0^{\infty} [g(x)]^q dx\right)^{1/q}.$$

The constant  $\pi \csc(\pi/P)$  is the best possible, in the sense that counterexamples can be constructed for any smaller value.

### Hilbert Matrix

A MATRIX  $H$  with elements

$$H_{ij} \equiv (i+j-1)^{-1}$$

for  $i, j = 1, 2, \dots, n$ . Although the MATRIX INVERSE is given analytically by

$$(H^{-1})_{ij} = \frac{(-1)^{i+j}}{i+j-1} \frac{(n+i-1)!(n+j-1)!}{[(i-1)!(j-1)!]^2 (n-i)!(n-j)!},$$

Hilbert matrices are difficult to invert numerically. The DETERMINANTS for the first few values of  $H_n$  are given in the following table.

$n$	$\det(H_n)$
1	1
2	$8.33333 \times 10^{-2}$
3	$4.62963 \times 10^{-4}$
4	$1.65344 \times 10^{-7}$
5	$3.74930 \times 10^{-12}$
6	$5.36730 \times 10^{-18}$

### Hilbert's Nullstellensatz

Let  $K$  be an algebraically closed field and let  $I$  be an IDEAL in  $K(x)$ , where  $x = (x_1, x_2, \dots, x_n)$  is a finite set of indeterminates. Let  $p \in K(x)$  be such that for any  $(c_1, \dots, c_n)$  in  $K^n$ , if every element of  $I$  vanishes when evaluated if we set each  $(x_i = c_i)$ , then  $p$  also vanishes. Then  $p^j$  lies in  $I$  for some  $j$ . Colloquially, the theory of algebraically closed fields is a complete model.

### Hilbert Number

see GELFOND-SCHNEIDER CONSTANT

### Hilbert Polynomial

Let  $\Gamma$  be an ALGEBRAIC CURVE in a projective space of DIMENSION  $n$ , and let  $p$  be the PRIME IDEAL defining  $\Gamma$ , and let  $\chi(p, m)$  be the number of linearly independent forms of degree  $m$  modulo  $p$ . For large  $m$ ,  $\chi(p, m)$  is a POLYNOMIAL known as the Hilbert polynomial.

### Hilbert's Problems

A set of (originally) unsolved problems in mathematics proposed by Hilbert. Of the 23 total, ten were presented at the Second International Congress in Paris in 1900. These problems were designed to serve as examples for the kinds of problems whose solutions would lead to the furthering of disciplines in mathematics.

- 1a. Is there a transfinite number between that of a DENUMERABLE SET and the numbers of the CONTINUUM? This question was answered by Gödel and Cohen to the effect that the answer depends on the particular version of SET THEORY assumed.
- 1b. Can the CONTINUUM of numbers be considered a WELL-ORDERED SET? This question is related to Zermelo's AXIOM OF CHOICE. In 1963, the AXIOM OF CHOICE was demonstrated to be independent of all other AXIOMS in SET THEORY, so there appears to be no universally valid solution to this question either.
2. Can it be proven that the AXIOMS of logic are consistent? GÖDEL'S INCOMPLETENESS THEOREM indicated that the answer is "no," in the sense

that any formal system interesting enough to formulate its own consistency can prove its own consistency IFF it is inconsistent.

3. Give two TETRAHEDRA which cannot be decomposed into congruent TETRAHEDRA directly or by adjoining congruent TETRAHEDRA. Max Dehn showed this could not be done in 1902. W. F. Kagon obtained the same result independently in 1903.
4. Find GEOMETRIES whose AXIOMS are closest to those of EUCLIDEAN GEOMETRY if the ORDERING and INCIDENCE AXIOMS are retained, the CONGRUENCE AXIOMS weakened, and the equivalent of the PARALLEL POSTULATE omitted. This problem was solved by G. Hamel.
5. Can the assumption of differentiability for functions defining a continuous transformation GROUP be avoided? (This is a generalization of the CAUCHY FUNCTIONAL EQUATION.) Solved by John von Neumann in 1930 for bicomact groups. Also solved for the ABELIAN case, and for the solvable case in 1952 with complementary results by Montgomery and Zipin (subsequently combined by Yamabe in 1953). Andrew Glean showed in 1952 that the answer is also "yes" for all locally bicomact groups.
6. Can physics be axiomized?
7. Let  $\alpha \neq 1 \neq 0$  be ALGEBRAIC and  $\beta$  IRRATIONAL. Is  $\alpha^\beta$  then TRANSCENDENTAL? Proved true in 1934 by Aleksander Gelfond (GELFOND'S THEOREM; Courant and Robins 1996).
8. Prove the RIEMANN HYPOTHESIS. The CONJECTURE has still been neither proved nor disproved.
9. Construct generalizations of the RECIPROCITY THEOREM of NUMBER THEORY.
10. Does there exist a universal algorithm for solving DIOPHANTINE EQUATIONS? The impossibility of obtaining a general solution was proven by Julia Robinson and Martin Davis in 1970, following proof of the result that the equation  $n = F_{2m}$  (where  $F_{2m}$  is a FIBONACCI NUMBER) is Diophantine by Yuri Matijasevich (Matijasevič 1970, Davis 1973, Davis and Hersch 1973, Matijasevič 1993).
11. Extend the results obtained for quadratic fields to arbitrary INTEGER algebraic fields.
12. Extend a theorem of Kronecker to arbitrary algebraic fields by explicitly constructing Hilbert class fields using special values. This calls for the construction of HOLOMORPHIC FUNCTIONS in several variables which have properties analogous to the exponential function and elliptic modular functions (Holtzapfel 1995).
13. Show the impossibility of solving the general seventh degree equation by functions of two variables.

14. Show the finiteness of systems of relatively integral functions.
15. Justify Schubert's ENUMERATIVE GEOMETRY (Bell 1945).
16. Develop a topology of REAL algebraic curves and surfaces. The SHIMURA-TANIYAMA CONJECTURE postulates just this connection. See Ilyashenko and Yakovenko (1995) and Gudkov and Utkin (1978).
17. Find a representation of definite form by SQUARES.
18. Build spaces with congruent POLYHEDRA.
19. Analyze the analytic character of solutions to variational problems.
20. Solve general BOUNDARY VALUE PROBLEMS.
21. Solve differential equations given a MONODROMY GROUP. More technically, prove that there always exists a FUCHSIAN SYSTEM with given singularities and a given MONODROMY GROUP. Several special cases had been solved, but a NEGATIVE solution was found in 1989 by B. Bolibruch (Anasov and Bolibruch 1994).
22. Uniformization.
23. Extend the methods of CALCULUS OF VARIATIONS.

Arfken, G. "Hilbert-Schmidt Theory." §16.4 in *Mathematical Methods for Physicists*, 3rd ed. Orlando, FL: Academic Press, pp. 890-897, 1985.

**Hilbert Space**

A Hilbert space is VECTOR SPACE  $H$  with an INNER PRODUCT  $\langle f, g \rangle$  such that the NORM defined by

$$|f| = \sqrt{\langle f, f \rangle}$$

turns  $H$  into a COMPLETE METRIC SPACE. If the INNER PRODUCT does not so define a NORM, it is instead known as an INNER PRODUCT SPACE.

Examples of FINITE-dimensional Hilbert spaces include

1. The REAL NUMBERS  $\mathbb{R}^n$  with  $\langle v, u \rangle$  the vector DOT PRODUCT of  $v$  and  $u$ .
2. The COMPLEX NUMBERS  $\mathbb{C}^n$  with  $\langle v, u \rangle$  the vector DOT PRODUCT of  $v$  and the COMPLEX CONJUGATE of  $u$ .

An example of an INFINITE-dimensional Hilbert space is  $L^2$ , the SET of all FUNCTIONS  $f: \mathbb{R} \rightarrow \mathbb{R}$  such that the INTEGRAL of  $f^2$  over the whole REAL LINE is FINITE. In this case, the INNER PRODUCT is

$$\langle f, g \rangle = \int f(x)g(x) dx.$$

A Hilbert space is always a BANACH SPACE, but the converse need not hold.

see also BANACH SPACE,  $L_2$ -NORM,  $L_2$ -SPACE, LIOUVILLE SPACE, PARALLELOGRAM LAW, VECTOR SPACE

Coolidge, J. L. *A Treatise on Algebraic Plane Curves*. New York: Dover, p. 61, 1959.

**Hilbert Transform**

$$g(y) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{f(x) dx}{x - y}$$

$$f(x) = \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{g(y) dy}{y - x}.$$

see also TITCHMARSH THEOREM

**References**

Bracewell, R. *The Fourier Transform and Its Applications*. New York: McGraw-Hill, pp. 267-272, 1965.

**Hill Determinant**

A DETERMINANT which arises in the solution of the second-order ORDINARY DIFFERENTIAL EQUATION

$$x^2 \frac{d^2 \psi}{dx^2} + x \frac{d\psi}{dx} + \left( \frac{1}{4} h^2 x^2 + \frac{1}{2} h^2 - b + \frac{h^2}{4x^2} \right) \psi = 0. \quad (1)$$

Writing the solution as a POWER SERIES

$$\psi = \sum_{n=-\infty}^{\infty} a_n x^{s+2n} \quad (2)$$

gives a RECURRENCE RELATION

$$h^2 a_{n+1} + [2h^2 - 4b + 16(n + \frac{1}{2}s)^2] a_n + h^2 a_{n-1} = 0. \quad (3)$$

The value of  $s$  can be computed using the Hill determinant

$$\Delta(s) = \begin{vmatrix} \ddots & \vdots & \vdots & \vdots & \vdots & \ddots \\ \cdots & \frac{(\sigma+2)-\alpha^2}{4-\alpha^2} & \frac{\beta^2}{4-\alpha^2} & 0 & 0 & \cdots \\ \cdots & 0 & -\frac{\beta^2}{\alpha^2} & -\frac{\sigma^2-\alpha^2}{\alpha^2} & -\frac{\beta^2}{\alpha^2} & \cdots \\ \cdots & 0 & 0 & -\frac{\beta^2}{1-\alpha^2} & \frac{(\sigma-1)^2-\alpha^2}{1-\alpha^2} & \cdots \\ \ddots & \vdots & \vdots & \vdots & \vdots & \ddots \end{vmatrix}, \quad (4)$$

where

$$\sigma = \frac{1}{2}s \quad (5)$$

$$\alpha^2 = \frac{1}{4}b - \frac{1}{8}h^2 \quad (6)$$

$$\beta = \frac{1}{4}h, \quad (7)$$

and  $\sigma$  is the variable to solve for. The determinant can be given explicitly by the amazing formula

$$\Delta(s) = \Delta(0) - \frac{\sin^2(\pi s/2)}{\sin^2(\frac{1}{2}\pi\sqrt{b - \frac{1}{2}h^2})}, \quad (8)$$

where

$$\Delta(0) = \begin{vmatrix} \ddots & \vdots & \vdots & \vdots & \vdots & \ddots \\ \cdots & 1 & \frac{h^2}{144+2h^2-4b} & 0 & 0 & \cdots \\ \cdots & \frac{h^2}{64+2h^2-4b} & 1 & \frac{h^2}{64+2h^2-4b} & 0 & \cdots \\ \cdots & 0 & \frac{h^2}{16+2h^2-4b} & 1 & \frac{h^2}{16+2h^2-4b} & \cdots \\ \cdots & 0 & 0 & \frac{h^2}{2h^2-4b} & 1 & \cdots \\ \cdots & 0 & 0 & 0 & \frac{h^2}{16+2h^2-4b} & \cdots \\ \ddots & \vdots & \vdots & \vdots & \vdots & \ddots \end{vmatrix}, \quad (9)$$

leading to the implicit equation for  $s$ ,

$$\sin^2(\frac{1}{2}\pi s) = \Delta(0) \sin^2\left(\frac{1}{2}\pi\sqrt{b - \frac{1}{2}h^2}\right). \quad (10)$$

### Hill's Differential Equation

$$\frac{d^2x}{dt^2} = \phi(t)x,$$

where  $\phi$  is periodic. It can be written as

$$\frac{d^2y}{dx^2} + \left[ \theta_0 + 2 \sum_{n=1}^{\infty} \theta_n \cos(2nz) \right] = 0,$$

where  $\theta_n$  are known constants. A solution can be given by taking the "DETERMINANT" of an infinite MATRIX.

see also HILL DETERMINANT

### Hillam's Theorem

If  $f: [a, b] \rightarrow [a, b]$  (where  $[a, b]$  denotes the CLOSED INTERVAL from  $a$  to  $b$  on the REAL LINE) satisfies a LIPSCHITZ CONDITION with constant  $K$ , i.e., if

$$|f(x) - f(y)| \leq K|x - y|$$

for all  $x, y \in [a, b]$ , then the iteration scheme

$$x_{n+1} = (1 - \lambda)x_n + \lambda f(x_n),$$

where  $\lambda = 1/(K + 1)$ , converges to a FIXED POINT of  $f$ .

### Hindu Check

see CASTING OUT NINES

### Hinge

The upper and lower hinges are descriptive statistics of a set of  $N$  data values, where  $N$  is of the form  $N = 4n + 5$  with  $n = 0, 1, 2, \dots$ . The hinges are obtained by ordering the data in increasing order  $a_1, \dots, a_N$ , and writing them out in the shape of a "w" as illustrated above. The values at the bottom legs are called the hinges  $H_1$  and  $H_2$  (and the central peak is the MEDIAN). In this ordering,

$$H_1 = a_{n+2} = a_{(N+3)/4}$$

$$M = a_{2n+3} = a_{(N+1)/2}$$

$$H_2 = a_{3n+4} = a_{(3N+1)/4}.$$

For  $N$  of the form  $4n + 5$ , the hinges are identical to the QUANTILES. The difference  $H_2 - H_1$  is called the H-SPREAD.

Owen, P. *Knots*. Philadelphia, PA: Courage, p. 17, 1993.

### Hitting Set

Let  $S$  be a collection  $S$  of subsets of a finite set  $X$ . The smallest subset  $Y$  of  $X$  that meets every member of  $S$  is called the hitting set or VERTEX COVER. Finding the hitting set is an NP-COMPLETE PROBLEM.

### Hjelmslev's Theorem

When all the points  $P$  on one line are related by an ISOMETRY to all points  $P'$  on another, the MIDPOINTS of the segments  $PP'$  are either distinct and collinear or coincident.

### HJLS Algorithm

An algorithm for finding INTEGER RELATIONS whose running time is bounded by a polynomial in the number of real variables. It is much faster than other algorithms such as the FERGUSON-FORCADE ALGORITHM, LLL ALGORITHM, and PSOS ALGORITHM.

Unfortunately, it is numerically unstable and therefore requires extremely high precision. The cause of this instability is not known (Ferguson and Bailey 1992), but is believed to derive from its reliance on GRAM-SCHMIDT ORTHONORMALIZATION, which is known to be numerically unstable (Golub and van Loan 1989).

Shenitzer, A. and Steprans, J. "The Evolution of Integration." *Amer. Math. Monthly* **101**, 66–72, 1994.

### Hodge Star

On an oriented  $n$ -D RIEMANNIAN MANIFOLD, the Hodge star is a linear FUNCTION which converts alternating DIFFERENTIAL  $k$ -FORMS to alternating  $(n - k)$ -forms. If  $w$  is an alternating  $k$ -FORM, its Hodge star is given by

$$w(v_1, \dots, v_k) = (*w)(v_{k+1}, \dots, v_n)$$

when  $v_1, \dots, v_n$  is an oriented orthonormal basis.

see also STOKES' THEOREM

### Hodge's Theorem

On a compact oriented FINSLER MANIFOLD without boundary, every COHOMOLOGY class has a UNIQUE harmonic representative. The DIMENSION of the SPACE of all harmonic forms of degree  $p$  is the  $p$ th BETTI NUMBER of the MANIFOLD.

see also BETTI NUMBER, COHOMOLOGY, DIMENSION, FINSLER MANIFOLD

### References

Chern, S.-S. "Finsler Geometry is Just Riemannian Geometry without the Quadratic Restriction." *Not. Amer. Math. Soc.* **43**, 959–963, 1996.

**Hoehn's Theorem**

A geometric theorem related to the PENTAGRAM and also called the PRATT-KASAPI THEOREM.

$$\frac{|V_1W_1|}{|W_2V_3|} \frac{|V_2W_2|}{|W_3V_4|} \frac{|V_3W_3|}{|W_4V_5|} \frac{|V_4W_4|}{|W_5V_1|} \frac{|V_5W_5|}{|W_1V_2|} = 1$$

$$\frac{|V_1W_2|}{|W_1V_3|} \frac{|V_2W_3|}{|W_2V_4|} \frac{|V_3W_4|}{|W_3V_5|} \frac{|V_4W_5|}{|W_4V_1|} \frac{|V_5W_1|}{|W_5V_2|} = 1.$$

In general, it is also true that

$$\frac{|V_iW_i|}{|W_{i+1}V_{i+2}|} = \frac{|V_iV_{i+1}V_{i+4}|}{|V_iV_{i+1}V_{i+2}V_{i+4}|} \frac{|V_iV_{i+1}V_{i+2}V_{i+3}|}{|V_{i+2}V_{i+3}V_{i+1}|}.$$

This type of identity was generalized to other figures in the plane and their duals by Pinkernell (1996).

**Hoffman's Minimal Surface**

A minimal embedded surface discovered in 1992 consisting of a helicoid with a HOLE and HANDLE (*Science News* 1992). It has the same topology as a punctured sphere with a handle, and is only the second complete embedded minimal surface of finite topology and infinite total curvature discovered (the HELICOID being the first).

A three-ended minimal surface GENUS 1 is sometimes also called Hoffman's minimal surface (Peterson 1988).

**Hofstadter-Conway \$10,000 Sequence**

The INTEGER SEQUENCE defined by the RECURRENCE RELATION

$$a(n) = a(a(n-1)) + a(n-a(n-1)),$$

with  $a(1) = a(2) = 1$ . The first few values are 1, 1, 2, 2, 3, 4, 4, 4, 5, 6, ... (Sloane's A004001). Plotting  $a(n)/n$  against  $n$  gives the BATRACHION plotted below. Conway (1988) showed that  $\lim_{n \rightarrow \infty} a(n)/n = 1/2$  and offered a prize of \$10,000 to the discoverer of a value of  $n$  for which  $|a(i)/i - 1/2| < 1/20$  for  $i > n$ . The prize was subsequently claimed by Mallows, after adjustment to Conway's "intended" prize of \$1,000 (Schroeder 1991), who found  $n = 1489$ .

$a(n)/n$  takes a value of  $1/2$  for  $n$  of the form  $2^k$  with  $k = 1, 2, \dots$ . Pickover (1996) gives a table of analogous values of  $n$  corresponding to different values of  $|a(n)/n - 1/2| < e$ .

### Hofstadter Figure-Figure Sequence

Define  $F(1) = 1$  and  $S(1) = 2$  and write

$$F(n) = F(n-1) + S(n-1),$$

where the sequence  $\{S(n)\}$  consists of those integers not already contained in  $\{F(n)\}$ . For example,  $F(2) = F(1) + S(1) = 3$ , so the next term of  $S(n)$  is  $S(2) = 4$ , giving  $F(3) = F(2) + S(2) = 7$ . The next integer is 5, so  $S(3) = 5$  and  $F(4) = F(3) + S(3) = 12$ . Continuing in this manner gives the "figure" sequence  $F(n)$  as 1, 3, 7, 12, 18, 26, 35, 45, 56, ... (Sloane's A005228) and the "space" sequence as 2, 4, 5, 6, 8, 9, 10, 11, 13, 14, ... (Sloane's A030124).

### Hofstadter G-Sequence

The sequence defined by  $G(0) = 0$  and

$$G(n) = n - G(G(n-1)).$$

The first few terms are 1, 1, 2, 3, 3, 4, 4, 5, 6, 6, 7, 8, 8, 9, 9, ... (Sloane's A005206).

### Hofstadter H-Sequence

The sequence defined by  $H(0) = 0$  and

$$H(n) = n - H(H(n-1)).$$

The first few terms are 1, 1, 2, 3, 4, 4, 5, 5, 6, 7, 7, 8, 9, 10, 10, 11, 12, 13, 13, 14, ... (Sloane's A005374).

### Hofstadter Male-Female Sequences

The pair of sequences defined by  $F(0) = 1$ ,  $M(0) = 0$ , and

$$F(n) = n - M(F(n-1))$$

$$M(n) = n - F(M(n-1)).$$

The first few terms of the "male" sequence  $M(n)$  are 0, 1, 2, 2, 3, 4, 4, 5, 6, 6, 7, 7, 8, 9, 9, ... (Sloane's A005379), and the first few terms of the "female" sequence  $F(n)$  are 1, 2, 2, 3, 3, 4, 5, 5, 6, 6, 7, 8, 8, 9, 9, ... (Sloane's A005378).

#### References

### Hofstadter Point

The  $r$ -HOFSTADTER TRIANGLE of a given TRIANGLE  $\triangle ABC$  is perspective to  $\triangle ABC$ , and the PERSPECTIVE CENTER is called the Hofstadter point. The TRIANGLE CENTER FUNCTION is

$$\alpha = \frac{\sin(rA)}{\sin(r-rA)}.$$

As  $r \rightarrow 0$ , the TRIANGLE CENTER FUNCTION approaches

$$\alpha = \frac{A}{a},$$

and as  $r \rightarrow 1$ , the TRIANGLE CENTER FUNCTION approaches

$$\alpha = \frac{a}{A}.$$

### Hofstadter's Q-Sequence

The INTEGER SEQUENCE given by

$$Q(n) = Q(n - Q(n-1)) + Q(n - Q(n-2)),$$

with  $Q(1) = Q(2) = 1$ . The first few values are 1, 1, 2, 3, 3, 4, 5, 5, 6, 6, 7, 7, 8, 9, 9, 10, 10, 11, 12, 13, 13, 14, ... (Sloane's A005185; illustrated above). These numbers are sometimes called Q-NUMBERS.

### Hofstadter Sequences

Let  $b_1 = 1$  and  $b_2 = 2$  and for  $n \geq 3$ , let  $b_n$  be the least INTEGER  $> b_{n-1}$  which can be expressed as the SUM of two or more consecutive terms. The resulting sequence is 1, 2, 3, 5, 6, 8, 10, 11, 14, 16, ... (Sloane's A005243). Let  $c_1 = 2$  and  $c_2 = 3$ , form all possible expressions of the form  $c_i c_j - 1$  for  $1 \leq i \leq j \leq n$ , and append them. The resulting sequence is 2, 3, 5, 9, 14, 16, 17, 18, ... (Sloane's A05244).

### Hofstadter Triangle

For a NONZERO REAL NUMBER  $r$  and a TRIANGLE  $\triangle ABC$ , swing LINE SEGMENT  $BC$  about the vertex  $B$  towards vertex  $A$  through an ANGLE  $rB$ . Call the line along the rotated segment  $L$ . Construct a second line  $L'$  by rotating LINE SEGMENT  $BC$  about vertex  $C$  through an ANGLE  $rC$ . Now denote the point of intersection of  $L$  and  $L'$  by  $A(r)$ . Similarly, construct  $B(r)$  and  $C(r)$ . The TRIANGLE having these points as vertices is called the Hofstadter  $r$ -triangle. Kimberling (1994) showed that the Hofstadter triangle is perspective to  $\triangle ABC$ , and calls PERSPECTIVE CENTER the HOFSTADTER POINT.

see also HOFSTADTER POINT

### Hölder Condition

A function  $\phi(t)$  satisfies the Hölder condition on two points  $t_1$  and  $t_2$  on an arc  $L$  when

$$|\phi(t_2) - \phi(t_1)| \leq A|t_2 - t_1|^\mu,$$

with  $A$  and  $\mu$  POSITIVE REAL constants.

### Hölder Integral Inequality

If

$$\frac{1}{p} + \frac{1}{q} = 1$$

with  $p, q > 1$ , then

$$\int_a^b |f(x)g(x)| dx \leq \left[ \int_a^b |f(x)|^p dx \right]^{1/p} \left[ \int_a^b |g(x)|^q dx \right]^{1/q},$$

with equality when

$$|g(x)| = c|f(x)|^{p-1}.$$

If  $p = q = 2$ , this inequality becomes SCHWARZ'S INEQUALITY.

### Hölder Sum Inequality

If

$$\frac{1}{p} + \frac{1}{q} = 1$$

with  $p, q > 1$ , then

$$\sum_{k=1}^n |a_k b_k| \leq \left( \sum_{k=1}^n |a_k|^p \right)^{1/p} \left( \sum_{k=1}^n |b_k|^q \right)^{1/q},$$

with equality when  $|b_k| = c|a_k|^{p-1}$ . If  $p = q = 2$ , this becomes the CAUCHY INEQUALITY.

## Hole

A hole in a mathematical object is a TOPOLOGICAL structure which prevents the object from being continuously shrunk to a point. When dealing with TOPOLOGICAL SPACES, a DISCONNECTIVITY is interpreted as a hole in the space. Examples of holes are things like the hole in the “center” of a SPHERE or a CIRCLE and the hole produced in EUCLIDEAN SPACE cutting a KNOT out from it.

Singular HOMOLOGY GROUPS form a MEASURE of the hole structure of a SPACE, but they are one particular measure and they don't always pick up everything. HOMOTOPY GROUPS of a SPACE are another measure of holes in a SPACE, as well as BORDISM GROUPS,  $k$ -THEORY, COHOMOTOPY GROUPS, and so on.

There are many ways to measure holes in a space. Some holes are picked up by HOMOTOPY GROUPS that are not picked up by HOMOLOGY GROUPS, and some holes are picked up by HOMOLOGY GROUPS that are not picked up by HOMOTOPY GROUPS. (For example, in the TORUS, HOMOTOPY GROUPS “miss” the two-dimensional hole that is given by the TORUS itself, but the second HOMOLOGY GROUP picks that hole up.) In addition, HOMOLOGY GROUPS don't pick up the varying hole structures of the complement of KNOTS in 3-space, but the first HOMOTOPY GROUP (the fundamental group) does.

## Holomorphic Function

A synonym for ANALYTIC FUNCTION.

see also ANALYTIC FUNCTION, HOMEOMORPHIC

## Holonomic Constant

A limiting value of a HOLONOMIC FUNCTION near a SINGULAR POINT. Holonomic constants include APÉRY'S CONSTANT, CATALAN'S CONSTANT, PÓLYA'S RANDOM WALK CONSTANTS for  $d > 2$ , and  $\pi$ .

## Holonomic Function

A solution of a linear homogeneous ORDINARY DIFFERENTIAL EQUATION with POLYNOMIAL COEFFICIENTS.

see also HOLONOMIC CONSTANT

### References

Zeilberger, D. “A Holonomic Systems Approach to Special Function Identities.” *J. Comput. Appl. Math.* **32**, 321–348, 1990.

## Holonomy

A general concept in CATEGORY THEORY involving the globalization of topological or differential structures.

see also MONODROMY

## Home Plate

Home plate in the game of BASEBALL is an irregular PENTAGON. However, the Little League rulebook's specification of the shape of home plate (Kreutzer and Kerley 1990), illustrated above, is not physically realizable, since it requires the existence of a (12, 12, 17) RIGHT TRIANGLE, whereas

$$12^2 + 12^2 = 288 \neq 289 = 17^2$$

(Bradley 1996).

see also BASEBALL COVER

## Homeoid

A shell bounded by two similar ELLIPSOIDS having a constant ratio of axes. Given a CHORD passing through a homeoid, the distance between inner and outer intersections is equal on both sides. Since a spherical shell is a symmetric case of a homeoid, this theorem is also true for spherical shells (CONCENTRIC CIRCLES in the PLANE), for which it is easily proved by symmetry arguments.

see also CHORD, ELLIPSOID

## Homeomorphic

There are two possible definitions:

1. Possessing similarity of form,
2. Continuous, ONE-TO-ONE, ONTO, and having a continuous inverse.

The most common meaning is possessing intrinsic topological equivalence. Two objects are homeomorphic if they can be deformed into each other by a continuous, invertible mapping. Homeomorphism ignores the space in which surfaces are embedded, so the deformation can be completed in a higher dimensional space than the surface was originally embedded. MIRROR IMAGES are homeomorphic, as are MÖBIUS BANDS with an EVEN number of half twists, and MÖBIUS BANDS with an ODD number of twists.

In CATEGORY THEORY terms, homeomorphisms are ISOMORPHISMS in the CATEGORY of TOPOLOGICAL SPACES and continuous maps.

see also HOMOMORPHIC, POLISH SPACE

**Homeomorphic Group**

If the ELEMENTS of two GROUPS are  $n$  to 1 and the correspondences satisfy the same GROUP multiplication table, the GROUPS are said to be homeomorphic.

see also ISOMORPHIC GROUPS

**Homeomorphic Type**

The following three pieces of information completely determine the homeomorphic type of the surface (Massey 1967):

1. Orientability,
2. Number of boundary components,
3. EULER CHARACTERISTIC.

see also ALGEBRAIC TOPOLOGY, EULER CHARACTERISTIC

**Homeomorphism**

see HOMEOMORPHIC, HOMEOMORPHIC GROUP, HOMEOMORPHIC TYPE, TOPOLOGICALLY CONJUGATE

**HOMFLY Polynomial**

A 2-variable oriented KNOT POLYNOMIAL  $P_L(a, z)$  motivated by the JONES POLYNOMIAL (Freyd *et al.* 1985). Its name is an acronym for the last names of its co-discoverers: Hoste, Ocneanu, Millett, Freyd, Lickorish, and Yetter (Freyd *et al.* 1985). Independent work related to the HOMFLY polynomial was also carried out by Przytycki and Traczyk (1987). HOMFLY polynomial is defined by the SKEIN RELATIONSHIP

$$a^{-1}P_{L_+}(a, z) - aP_{L_-}(a, z) = zP_{L_0}(a, z) \quad (1)$$

(Doll and Hoste 1991), where  $v$  is sometimes written instead of  $a$  (Kanenobu and Sumi 1993) or, with a slightly different relationship, as

$$\alpha P_{L_+}(\alpha, z) - \alpha^{-1}P_{L_-}(\alpha, z) = zP_{L_0}(\alpha, z) \quad (2)$$

(Kauffman 1991). It is also defined as  $P_L(\ell, m)$  in terms of SKEIN RELATIONSHIP

$$\ell P_{L_+} + \ell^{-1}P_{L_-} + mP_{L_0} = 0 \quad (3)$$

(Lickorish and Millett 1988). It can be regarded as a nonhomogeneous POLYNOMIAL in two variables or a homogeneous POLYNOMIAL in three variables. In three variables the SKEIN RELATIONSHIP is written

$$xP_{L_+}(x, y, z) + yP_{L_-}(x, y, z) + zP_{L_0}(x, y, z) = 0. \quad (4)$$

It is normalized so that  $P_{\text{unknot}} = 1$ . Also, for  $n$  unlinked unknotted components,

$$P_L(x, y, z) = \left(-\frac{x+y}{z}\right)^{n-1}. \quad (5)$$

This POLYNOMIAL usually detects CHIRALITY but does not detect the distinct ENANTIOMERS of the KNOTS  $09_{042}$ ,  $10_{048}$ ,  $10_{071}$ ,  $10_{091}$ ,  $10_{104}$ , and  $10_{125}$  (Jones 1987). The HOMFLY polynomial of an oriented KNOT is the same if the orientation is reversed. It is a generalization of the JONES POLYNOMIAL  $V(t)$ , satisfying

$$V(t) = P(a = t, z = t^{1/2} - t^{-1/2}) \quad (6)$$

$$V(t) = P(\ell = it^{-1}, m = i(t^{-1/2} - t^{1/2})). \quad (7)$$

It is also a generalization of the ALEXANDER POLYNOMIAL  $\nabla(z)$ , satisfying

$$\Delta(z) = P(a = 1, z = t^{1/2} - t^{-1/2}). \quad (8)$$

The HOMFLY POLYNOMIAL of the MIRROR IMAGE  $K^*$  of a KNOT  $K$  is given by

$$P_{K^*}(\ell, m) = P_K(\ell^{-1}, m), \quad (9)$$

so  $P$  usually but not always detects CHIRALITY.

A split union of two links (i.e., bringing two links together without intertwining them) has HOMFLY polynomial

$$P(L_1 \cup L_2) = -(\ell + \ell^{-1})m^{-1}P(L_1)P(L_2). \quad (10)$$

Also, the composition of two links

$$P(L_1 \# L_2) = P(L_1)P(L_2), \quad (11)$$

so the POLYNOMIAL of a COMPOSITE KNOT factors into POLYNOMIALS of its constituent knots (Adams 1994).

MUTANTS have the same HOMFLY polynomials. In fact, there are infinitely many distinct KNOTS with the same HOMFLY POLYNOMIAL (Kanenobu 1986). Examples include  $(05_{001}, 10_{132})$ ,  $(08_{008}, 10_{129})$ ,  $(08_{016}, 10_{156})$ , and  $(10_{025}, 10_{056})$  (Jones 1987). Incidentally, these also have the same JONES POLYNOMIAL.

M. B. Thistlethwaite has tabulated the HOMFLY polynomial for KNOTS up to 13 crossings.

## Homoclinic Point

A point where a stable and an unstable separatrix (invariant manifold) from the same fixed point or same family intersect. Therefore, the limits

$$\lim_{k \rightarrow \infty} f^k(X)$$

and

$$\lim_{k \rightarrow -\infty} f^k(X)$$

exist and are equal.

Refer to the above figure. Let  $X$  be the point of intersection, with  $X_1$  ahead of  $X$  on one MANIFOLD and  $X_2$  ahead of  $X$  of the other. The mapping of each of these points  $TX_1$  and  $TX_2$  must be ahead of the mapping of  $X$ ,  $TX$ . The only way this can happen is if the MANIFOLD loops back and crosses itself at a new homoclinic point. Another loop must be formed, with  $T^2X$  another homoclinic point. Since  $T^2X$  is closer to the hyperbolic point than  $TX$ , the distance between  $T^2X$  and  $TX$  is less than that between  $X$  and  $TX$ . Area preservation requires the AREA to remain the same, so each new curve (which is closer than the previous one) must extend further. In effect, the loops become longer and thinner. The network of curves leading to a dense AREA of homoclinic points is known as a homoclinic tangle or tendril. Homoclinic points appear where CHAOTIC regions touch in a hyperbolic FIXED POINT.

A small DISK centered near a homoclinic point includes infinitely many periodic points of different periods. Poincaré showed that if there is a single homoclinic point, there are an infinite number. More specifically, there are infinitely many homoclinic points in each small disk (Nusse and Yorke 1996).

see also HETEROCLINIC POINT

## Homogeneous Coordinates

see TRILINEAR COORDINATES

## Homogeneous Function

A function which satisfies

$$f(tx, ty) = t^n f(x, y)$$

for a fixed  $n$ . MEANS, the WEIERSTRASS ELLIPTIC FUNCTION, and TRIANGLE CENTER FUNCTIONS are homogeneous functions. A transformation of the variables of a TENSOR changes the TENSOR into another whose components are linear homogeneous functions of the components of the original TENSOR.

see also EULER'S HOMOGENEOUS FUNCTION THEOREM

## Homogeneous Numbers

Two numbers are homogeneous if they have identical PRIME FACTORS. An example of a homogeneous pair is (6, 36), both of which share PRIME FACTORS 2 and 3:

$$\begin{aligned} 6 &= 2 \cdot 3 \\ 36 &= 2^2 \cdot 3^2 \end{aligned}$$

see also HETEROGENEOUS NUMBERS, PRIME FACTORS, PRIME NUMBER

## References

- Le Lionnais, F. *Les nombres remarquables*. Paris: Hermann, p. 146, 1983.

## Homogeneous Polynomial

A multivariate polynomial (i.e., a POLYNOMIAL in more than one variable) with all terms having the same degree. For example,  $x^3 + xyz + y^2z + z^3$  is a homogeneous polynomial of degree three.

see also POLYNOMIAL

## Homographic

see MÖBIUS TRANSFORMATION

## Homography

A CIRCLE-preserving transformation composed of an EVEN number of inversions.

see also ANTIHOMOGRAPHY

**Homological Algebra**

An abstract ALGEBRA concerned with results valid for many different kinds of SPACES.

References

**Homolographic Equal Area Projection**

see MOLLWEIDE PROJECTION

**Homology (Geometry)**

A PERSPECTIVE COLLINEATION in which the center and axis are not incident.

see also ELATION, HARMONIC HOMOLOGY, PERSPECTIVE COLLINEATION

**Homology Group**

The term "homology group" usually means a singular homology group, which is an ABELIAN GROUP which partially counts the number of HOLES in a TOPOLOGICAL SPACE. In particular, singular homology groups form a MEASURE of the HOLE structure of a SPACE, but they are one particular measure and they don't always pick up everything.

In addition, there are "generalized homology groups" which are *not* singular homology groups.

**Homology (Topology)**

Historically, the term "homology" was first used in a topological sense by Poincaré. To him, it meant pretty much what is now called a COBORDISM, meaning that a homology was thought of as a relation between MANIFOLDS mapped into a MANIFOLD. Such MANIFOLDS form a homology when they form the boundary of a higher-dimensional MANIFOLD inside the MANIFOLD in question.

To simplify the definition of homology, Poincaré simplified the spaces he dealt with. He assumed that all the spaces he dealt with had a triangulation (i.e., they were "SIMPLICIAL COMPLEXES"). Then instead of talking about general "objects" in these spaces, he restricted himself to subcomplexes, i.e., objects in the space made up only on the simplices in the TRIANGULATION of the space. Eventually, Poincaré's version of homology was

dispensed with and replaced by the more general SINGULAR HOMOLOGY. SINGULAR HOMOLOGY is the concept mathematicians mean when they say "homology."

In modern usage, however, the word homology is used to mean HOMOLOGY GROUP. For example, if someone says "X did Y by computing the homology of Z," they mean "X did Y by computing the HOMOLOGY GROUPS of Z." But sometimes homology is used more loosely in the context of a "homology in a SPACE," which corresponds to *singular* homology groups.

Singular homology groups of a SPACE measure the extent to which there are finite (compact) boundaryless GADGETS in that SPACE, such that these GADGETS are not the boundary of other finite (compact) GADGETS in that SPACE.

A generalized homology or cohomology theory must satisfy all of the EILENBERG-STEENROD AXIOMS with the exception of the DIMENSION AXIOM.

see also COHOMOLOGY, DIMENSION AXIOM, EILENBERG-STEENROD AXIOMS, GADGET, HOMOLOGICAL ALGEBRA, HOMOLOGY GROUP, SIMPLICIAL COMPLEX, SIMPLICIAL HOMOLOGY, SINGULAR HOMOLOGY

**Homomorphic**

Related to one another by a HOMOMORPHISM.

**Homomorphism**

A term used in CATEGORY THEORY to mean a general MORPHISM.

see also HOMEOMORPHISM, MORPHISM

**Homoscedastic**

A set of STATISTICAL DISTRIBUTIONS having the same VARIANCE.

see also HETEROSCEDASTIC

**Homothecy**

see DILATION

**Homothetic**

Two figures are homothetic if they are related by a DILATION (a dilation is also known as a HOMOTHECY). This means that they lie in the same plane and corresponding sides are PARALLEL; such figures have connectors of corresponding points which are CONCURRENT at a point known as the HOMOTHETIC CENTER. The HOMOTHETIC CENTER divides each connector in the same ratio  $k$ , known as the SIMILITUDE RATIO. For figures which are similar but do not have PARALLEL sides, a SIMILITUDE CENTER exists.

see also DILATION, HOMOTHETIC CENTER, PERSPECTIVE, SIMILITUDE RATIO

References

- Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, 1929.

## Homothetic Center

The meeting point of lines that connect corresponding points from HOMOTHETIC figures. In the above figure,  $O$  is the homothetic center of the HOMOTHETIC figures  $ABCDE$  and  $A'B'C'D'E'$ . For figures which are similar but do not have PARALLEL sides, a SIMILITUDE CENTER exists (Johnson 1929, pp. 16–20).

Given two nonconcentric CIRCLES, draw RADII PARALLEL and in the same direction. Then the line joining the extremities of the RADII passes through a fixed point on the line of centers which divides that line externally in the ratio of RADII. This point is called the external homothetic center, or external center of similitude (Johnson 1929, pp. 19–20 and 41).

If RADII are drawn PARALLEL but instead in opposite directions, the extremities of the RADII pass through a fixed point on the line of centers which divides that line internally in the ratio of RADII (Johnson 1929, pp. 19–20 and 41). This point is called the internal homothetic center, or internal center of similitude (Johnson 1929, pp. 19–20 and 41).

The position of the homothetic centers for two circles of radii  $r_i$ , centers  $(x_i, y_i)$ , and segment angle  $\theta$  are given by solving the simultaneous equations

$$y - y_2 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_2)$$

$$y - y_2^\pm = \frac{y_2^\pm - y_1^\pm}{x_2^\pm - x_1^\pm}(x - x_2^\pm)$$

for  $(x, y)$ , where

$$x_i^\pm \equiv x_i + (-1)^i r_i \cos \theta$$

$$y_i^\pm \equiv y_i + (-1)^i r_i \sin \theta,$$

and the plus signs give the external homothetic center, while the minus signs give the internal homothetic center.

As the above diagrams show, as the angles of the parallel segments are varied, the positions of the homothetic centers remain the same. This fact provides a (slotted) LINKAGE for converting circular motion with one radius to circular motion with another.

The six homothetic centers of three circles lie three by three on four lines (Johnson 1929, p. 120), which “enclose” the smallest circle.

The homothetic center of triangles is the PERSPECTIVE CENTER of HOMOTHETIC TRIANGLES. It is also called the SIMILITUDE CENTER (Johnson 1929, pp. 16–17).

see also APOLLONIUS' PROBLEM, PERSPECTIVE, SIMILITUDE CENTER

## Homothetic Position

Two similar figures with PARALLEL homologous LINES and connectors of HOMOLOGOUS POINTS CONCURRENT at the HOMOTHETIC CENTER are said to be in homothetic position. If two SIMILAR figures are in the same plane but the corresponding sides are not PARALLEL, there exists a self-HOMOLOGOUS POINT which occupies the same homologous position with respect to the two figures.

**Homothetic Triangles**

Nonconcurrent TRIANGLES with PARALLEL sides are always HOMOTHETIC. Homothetic triangles are always PERSPECTIVE TRIANGLES. Their PERSPECTIVE CENTER is called their HOMOTHETIC CENTER.

**Homotopy**

A continuous transformation from one FUNCTION to another. A homotopy between two functions  $f$  and  $g$  from a SPACE  $X$  to a SPACE  $Y$  is a continuous MAP  $G$  from  $X \in [0, 1] \mapsto Y$  such that  $G(x, 0) = f(x)$  and  $G(x, 1) = g(x)$ . Another way of saying this is that a homotopy is a path in the mapping SPACE  $\text{Map}(X, Y)$  from the first FUNCTION to the second.

see also h-COBORDISM

**Homotopy Axiom**

One of the EILENBERG-STENROD AXIOMS which states that, if  $f : (X, A) \rightarrow (Y, B)$  is homotopic to  $g : (X, A) \rightarrow (Y, B)$ , then their INDUCED MAPS  $f_* : H_n(X, A) \rightarrow H_n(Y, B)$  and  $g_* : H_n(X, A) \rightarrow H_n(Y, B)$  are the same.

**Homotopy Group**

A GROUP related to the HOMOTOPY classes of MAPS from SPHERES  $S^n$  into a SPACE  $X$ .

see also COHOMOTOPY GROUP

**Homotopy Theory**

The branch of ALGEBRAIC TOPOLOGY which deals with HOMOTOPY GROUPS.

**References**

Aubry, M. *Homotopy Theory and Models*. Boston, MA: Birkhäuser, 1995.

**Honeycomb**

A TESSELLATION in  $n$ -D, for  $n \geq 3$ . The only regular honeycomb in 3-D is  $\{4, 3, 4\}$ , which consists of eight cubes meeting at each VERTEX. The only quasiregular honeycomb (with regular cells and semiregular VERTEX FIGURES) has each VERTEX surrounded by eight TETRAHEDRA and six OCTAHEDRA and is denoted  $\left\{ \begin{smallmatrix} 3 \\ 3, 4 \end{smallmatrix} \right\}$ .

There are many semiregular honeycombs, such as  $\left\{ \begin{smallmatrix} 3, 3 \\ 4 \end{smallmatrix} \right\}$ , in which each VERTEX consists of two OCTAHEDRA  $\{3, 4\}$  and four CUBOCTAHEDRA  $\left\{ \begin{smallmatrix} 3 \\ 4 \end{smallmatrix} \right\}$ .

**Hopf Circle**

see HOPF MAP

**Hopf Link**

The LINK  $2_1^2$  which has JONES POLYNOMIAL

$$V(t) = -t - t^{-1}$$

and HOMFLY POLYNOMIAL

$$P(z, \alpha) = z^{-1}(\alpha^{-1} - \alpha^{-3}) + z\alpha^{-1}.$$

It has BRAID WORD  $\sigma_1^2$ .

### Hopf Map

The first example discovered of a MAP from a higher-dimensional SPHERE to a lower-dimensional SPHERE which is not null-HOMOTOPIC. Its discovery was a shock to the mathematical community, since it was believed at the time that all such maps were null-HOMOTOPIC, by analogy with HOMOLOGY GROUPS. The Hopf map takes points  $(X_1, X_2, X_3, X_4)$  on a 3-sphere to points on a 2-sphere  $(x_1, x_2, x_3)$

$$\begin{aligned}x_1 &= 2(X_1X_2 + X_3X_4) \\x_2 &= 2(X_1X_4 - X_2X_3) \\x_3 &= (X_1^2 + X_3^2) - (X_2^2 + X_4^2).\end{aligned}$$

Every point on the two SPHERES corresponds to a CIRCLE called the HOPF CIRCLE on the 3-SPHERE.

### Hopf's Theorem

A NECESSARY and SUFFICIENT condition for a MEASURE which is quasi-invariant under a transformation to be equivalent to an invariant PROBABILITY MEASURE is that the transformation cannot (in a measure theoretic sense) compress the SPACE.

### Horizontal

Oriented in position PERPENDICULAR to up-down, and therefore PARALLEL to a flat surface.

see also VERTICAL

### Horizontal-Vertical Illusion

see VERTICAL-HORIZONTAL ILLUSION

### Horn Angle

The configuration formed by two curves starting at a point, called the VERTEX  $V$ , in a common direction. They are concrete illustrations of non-Archimedean geometries.

#### References

Kasner, E. "The Recent Theory of the Horn Angle." *Scripta Math* 11, 263–267, 1945.

### Horn Cyclide

The inversion of a HORN TORUS. If the inversion center lies on the torus, then the horn cyclide degenerates to a PARABOLIC HORN CYCLIDE.

see also CYCLIDE, HORN TORUS, PARABOLIC CYCLIDE, RING CYCLIDE, SPINDLE CYCLIDE, TORUS

### Horn Torus

One of the three STANDARD TORI given by the parametric equations

$$x = (c + a \cos v) \cos u \quad (1)$$

$$y = (c + a \cos v) \sin u \quad (2)$$

$$z = a \sin v \quad (3)$$

with  $a = c$ . The inversion of a horn torus is a HORN CYCLIDE (or PARABOLIC HORN CYCLIDE). The above left figure shows a horn torus, the middle a cutaway, and the right figure shows a CROSS-SECTION of the horn torus through the  $xz$ -plane.

### Horned Sphere

see ALEXANDER'S HORNED SPHERE, ANTOINE'S HORNED SPHERE

### Horner's Method

Let

$$P(x) = a_n x^n + \dots + a_0 \quad (1)$$

and  $b_n \equiv a_n$ . If we then define

$$b_k \equiv a_k + b_{k-1}x_0 \quad (2)$$

for  $k = n - 1, n - 2, \dots, 0$ , we obtain  $b_0 = P(x_0)$ . It therefore follows that

$$P(x) = (x - x_0)Q(x) + b_0, \quad (3)$$

where

$$Q(x) \equiv b_n x^{n-1} + b_{n-1} x^{n-2} + \dots + b_2 x + b_1. \quad (4)$$

In addition,

$$P'(x) = Q(x) + (x - x_0)Q'(x) \quad (5)$$

$$P'(x_0) = Q(x_0). \quad (6)$$

**Horner's Rule**

A rule for POLYNOMIAL computation which both reduces the number of necessary multiplications and results in less numerical instability due to potential subtraction of one large number from another. The rule simply factors out POWERS of  $x$ , giving

$$a_n x^n + a_{n-1} x^{n-1} + \dots + a_0 = ((a_n x + a_{n-1})x + \dots)x + a_0.$$

**References**

## Hurwitz's Irrational Number Theorem

As Lagrange showed, any IRRATIONAL NUMBER  $\alpha$  has an infinity of rational approximations  $p/q$  which satisfy

$$\left| \alpha - \frac{p}{q} \right| < \frac{1}{\sqrt{5} q^2}. \quad (1)$$

Similarly, if  $\alpha \neq \frac{1}{2}(1 + \sqrt{5})$ ,

$$\left| \alpha - \frac{p}{q} \right| < \frac{1}{\sqrt{8} q^2}, \quad (2)$$

and if  $\alpha \neq \frac{1}{2}(1 + \sqrt{5}) \neq \sqrt{2}$ ,

$$\left| \alpha - \frac{p}{q} \right| < \frac{5}{\sqrt{221} q^2}. \quad (3)$$

In general, even tighter bounds of the form

$$\left| \alpha - \frac{p}{q} \right| < \frac{1}{L_n q^2} \quad (4)$$

can be obtained for the best rational approximation possible for an arbitrary irrational number  $\alpha$ , where the  $L_n$  are called LAGRANGE NUMBERS and get steadily larger for each "bad" set of irrational numbers which is excluded.

## Hurwitz Polynomial

A POLYNOMIAL with REAL POSITIVE COEFFICIENTS and ROOTS which are either NEGATIVE or pairwise conjugate with NEGATIVE REAL PARTS.

**Hurwitz-Radon Theorem**

Determined the possible values of  $r$  and  $n$  for which there is an IDENTITY of the form

$$(x_1^2 + \dots + x_r^2)(y_1^2 + \dots + y_r^2) = z_1^2 + \dots + z_n^2.$$

**Hurwitz's Root Theorem**

Let  $\{f(x)\}$  be a SEQUENCE of ANALYTIC FUNCTIONS REGULAR in a region  $G$ , and let this sequence be UNIFORMLY CONVERGENT in every CLOSED SUBSET of  $G$ . If the ANALYTIC FUNCTION

$$\lim_{n \rightarrow \infty} f_n(x) = f(x)$$

does not vanish identically, then if  $x = a$  is a zero of  $f(x)$  of order  $k$ , a NEIGHBORHOOD  $|x - a| < \delta$  of  $x = a$  and a number  $N$  exist such that if  $n > N$ ,  $f_n(x)$  has exactly  $k$  zeros in  $|x - a| < \delta$ .

**References**

Szegő, G. *Orthogonal Polynomials*, 4th ed. Providence, RI: Amer. Math. Soc., p. 22, 1975.

**Hurwitz Zeta Function**

A generalization of the RIEMANN ZETA FUNCTION with a FORMULA

$$\zeta(s, a) \equiv \sum_{k=0}^{\infty} \frac{1}{(k+a)^s}, \quad (1)$$

where any term with  $k+a=0$  is excluded. The Hurwitz zeta function can also be given by the functional equation

$$\begin{aligned} & \zeta\left(s, \frac{p}{q}\right) \\ &= 2\Gamma(1-s)(2\pi q)^{s-1} \sum_{n=1}^q \sin\left(\frac{\pi s}{2} + \frac{2\pi np}{q}\right) \zeta\left(1-s, \frac{n}{q}\right) \end{aligned} \quad (2)$$

(Apostol 1976, Miller and Adamchik), or the integral

$$\begin{aligned} \zeta(s, a) &= \frac{1}{2}a^{-s} + \frac{a^{1-s}}{s-1} \\ &+ 2 \int_0^{\infty} (a^2 + y^2)^{-s/2} \left\{ \sin \left[ s \tan^{-1} \left( \frac{y}{a} \right) \right] \right\} \frac{dy}{e^{2\pi y} - 1}. \end{aligned} \quad (3)$$

If  $\Re[z] < 0$ , then

$$\begin{aligned} \zeta(z, a) &= \frac{2\Gamma(1-z)}{(2\pi)^{1-z}} \left[ \sin\left(\frac{\pi z}{2}\right) \sum_{n=1}^{\infty} \frac{\cos(2\pi an)}{n^{1-z}} \right. \\ &\quad \left. + \cos\left(\frac{\pi z}{2}\right) \sum_{n=1}^{\infty} \frac{\sin(2\pi an)}{n^{1-z}} \right]. \end{aligned} \quad (4)$$

The Hurwitz zeta function satisfies

$$\zeta(0, a) = \frac{1}{2} - a \quad (5)$$

$$\frac{d}{ds} \zeta(0, a) = \ln[\Gamma(a)] - \frac{1}{2} \ln(2\pi) \quad (6)$$

$$\frac{d}{ds} \zeta(0, 0) = \frac{1}{2} \ln(2\pi), \quad (7)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION. The POLYGAMMA FUNCTION  $\psi_m(z)$  can be expressed in terms of the Hurwitz zeta function by

$$\psi_m(z) = (-1)^{m+1} m! \zeta(1+m, z). \quad (8)$$

For POSITIVE integers  $k$ ,  $p$ , and  $q > p$ ,

$$\begin{aligned} \zeta'\left(-2k+1, \frac{p}{q}\right) &= \frac{[\psi(2k) - \ln(2\pi q)]B_{2k}(p/q)}{2k} \\ &- \frac{[\psi(2k) - \ln(2\pi)]B_{2k}}{q^{2k}2k} \\ &+ \frac{(-1)^{k+1}\pi}{(2\pi q)^{2k}} \sum_{n=1}^{q-1} \sin\left(\frac{2\pi pn}{q}\right) \psi_{(2k-1)}\left(\frac{n}{q}\right) \\ &+ \frac{(-1)^{k+1}2(2k-1)!}{(2\pi q)^{2k}} \sum_{n=1}^{q-1} \cos\left(\frac{2\pi pn}{q}\right) \zeta'\left(2k, \frac{n}{q}\right) \\ &+ \frac{\zeta'(-2k+1)}{q^{2k}}, \end{aligned} \quad (9)$$

where  $B_n$  is a BERNOULLI NUMBER,  $B_n(x)$  a BERNOULLI POLYNOMIAL,  $\psi_n(z)$  is a POLYGAMMA FUNCTION, and  $\zeta(z)$  is a RIEMANN ZETA FUNCTION (Miller and Adamchik). Miller and Adamchik also give the closed-form expressions

$$\zeta'(-2k+1, \frac{1}{2}) = -\frac{B_{2k} \ln 2}{4^k k} - \frac{(2^{2k-1} - 1)\zeta'(-2k+1)}{2^{2k-1}} \quad (10)$$

$$\begin{aligned} \zeta'\left(-2k+1, \frac{1}{3}\right) &= \mp \frac{(9^k - 1)B_{2k}\pi}{\sqrt{3}(3^{2k-1} - 1)8k} - \frac{B_{2k} \ln 3}{(3^{2k-1})4k} \\ &\mp \frac{(-1)^k \psi_{2k-1}(\frac{1}{3})}{2\sqrt{3}(6\pi)^{2k-1}} - \frac{(3^{2k-1} - 1)\zeta'(-2k+1)}{2(3^{2k-1})} \end{aligned} \quad (11)$$

$$\begin{aligned} \zeta'\left(-2k+1, \frac{1}{4}\right) &= \mp \frac{(4^k + 1)B_{2k}\pi}{4^{k+1}k} + \frac{(4^{k-1} - 1)B_{2k} \ln 2}{2^{3k-1}k} \\ &\mp \frac{(-1)^k \psi_{2k-1}(\frac{1}{4})}{4(8\pi)^{2k-1}} - \frac{(2^{2k-1} - 1)\zeta'(-2k+1)}{2^{4k-1}} \end{aligned} \quad (12)$$

$$\begin{aligned} \zeta'\left(-2k+1, \frac{1}{6}\right) &= \mp \frac{(9^k - 1)(2^{2k-1} + 1)B_{2k}\pi}{\sqrt{3}(6^{2k-1})8k} \\ &+ \frac{B_{2k}(3^{2k-1} - 1) \ln 2}{(6^{2k-1})4k} + \frac{B_{2k}(2^{2k-1} - 1) \ln 3}{(6^{2k-1})4k} \\ &\mp \frac{(-1)^k (2^{2k-1} + 1) \psi_{2k-1}(\frac{1}{3})}{2\sqrt{3}(12\pi)^{2k-1}} \\ &+ \frac{(2^{2k-1} - 1)(3^{2k-1} - 1)\zeta'(-2k+1)}{2(6^{2k-1})}. \end{aligned} \quad (13)$$

### Hutton's Formula

The MACHIN-LIKE FORMULA

$$\frac{1}{4}\pi = 2 \tan^{-1}\left(\frac{1}{3}\right) + \tan^{-1}\left(\frac{1}{7}\right).$$

The other two-term MACHIN-LIKE FORMULAS are EULER'S MACHIN-LIKE FORMULA, HERMANN'S FORMULA, and MACHIN'S FORMULA.

### Hutton's Method

see LAMBERT'S METHOD

### Hyperbola

In general, a hyperbola is defined as the LOCUS of all points in the PLANE the difference of whose distance from two fixed points (the FOCI  $F_1$  and  $F_2$ ) separated by a distance  $2c$ , where

$$c \equiv \sqrt{a^2 + b^2}, \quad (1)$$

is a given POSITIVE constant. By analogy with the definition of the ELLIPSE, the equation for a hyperbola with SEMIMAJOR AXIS  $a$  parallel to the  $x$ -AXIS and SEMIMINOR AXIS  $b$  parallel to the  $y$ -AXIS is given by

$$\frac{(x - x_0)^2}{a^2} - \frac{(y - y_0)^2}{b^2} = 1. \quad (2)$$

Unlike the ELLIPSE, no points of the hyperbola actually lie on the SEMIMINOR AXIS, but rather the ratio  $b/a$  determined the vertical scaling of the hyperbola. The ECCENTRICITY of the hyperbola is defined as

$$e \equiv \frac{c}{a} = \sqrt{1 + \frac{b^2}{a^2}}. \quad (3)$$

In the standard equation of the hyperbola, the center is located at  $(x_0, y_0)$ , the FOCI are at  $(x_0 \pm c, y_0)$ , and the vertices are at  $(x_0 \pm a, y_0)$ . The so-called ASYMPTOTES (shown as the dashed lines in the above figures) can be found by substituting 0 for the 1 on the right side of the general equation (2),

$$y = \pm \frac{b}{a}(x - x_0) + y_0, \quad (4)$$

and therefore have SLOPES  $\pm b/a$ .

The special case  $a = b$  (the left diagram above) is known as a RIGHT HYPERBOLA because the ASYMPTOTES are PERPENDICULAR.

In POLAR COORDINATES, the equation of a hyperbola centered at the ORIGIN (i.e., with  $x_0 = y_0 = 0$ ) is

$$r^2 = \frac{a^2 b^2}{b^2 \cos^2 \theta - a^2 \sin^2 \theta}. \quad (5)$$

In POLAR COORDINATES centered at a FOCUS,

$$r = \frac{a(e^2 - 1)}{1 - e \cos \theta}. \quad (6)$$

The two-center BIPOLAR COORDINATES equation with origin at a FOCUS is

$$r_1 - r_2 = \pm 2a. \quad (7)$$

The parametric equations for the hyperbola are

$$x = \pm a \cosh t \quad (8)$$

$$y = b \sinh t. \quad (9)$$

The CURVATURE and TANGENTIAL ANGLE are

$$\kappa(t) = -[\cosh(2t)]^{-3/2} \quad (10)$$

$$\phi(t) = -\tan^{-1}(\tanh t). \quad (11)$$

The special case of the RIGHT HYPERBOLA was first studied by Menaechmus. Euclid and Aristaeus wrote about the general hyperbola, but only studied one branch of it. The hyperbola was given its present name by Apollonius, who was the first to study both branches. The FOCUS and DIRECTRIX were considered by Pappus (MacTutor Archive). The hyperbola is the shape of an orbit of a body on an escape trajectory (i.e., a body

with positive energy), such as some comets, about a fixed mass, such as the sun.

The LOCUS of the apex of a variable CONE containing an ELLIPSE fixed in 3-space is a hyperbola through the FOCI of the ELLIPSE. In addition, the LOCUS of the apex of a CONE containing that hyperbola is the original ELLIPSE. Furthermore, the ECCENTRICITIES of the ELLIPSE and hyperbola are reciprocals.

### Hyperbola Evolute

The EVOLUTE of a RECTANGULAR HYPERBOLA is the LAMÉ CURVE

$$(ax)^{2/3} - (by)^{2/3} = (a+b)^{2/3}.$$

From a point between the two branches of the EVOLUTE, two NORMALS can be drawn to the HYPERBOLA. However, from a point beyond the EVOLUTE, four NORMALS can be drawn.

### Hyperbola Inverse Curve

For a HYPERBOLA with  $a = b$  with INVERSION CENTER at the center, the INVERSE CURVE

$$x = \frac{2k \cos t}{a[3 - \cos(2t)]} \quad (1)$$

$$y = \frac{k \sin(2t)}{a[3 - \cos(2t)]} \quad (2)$$

is a LEMNISCATE.

For an INVERSION CENTER at the VERTEX, the INVERSE CURVE

$$x = a + \frac{4k \cos t \sin^2(\frac{1}{2}t)}{a[5 - 4 \cos t + \cos(2t) - 2 \sin(2t)]} \quad (3)$$

$$y = a + \frac{k(\tan t - 1)}{a[(\sec t - 1)^2 + (\tan t - 1)^2]} \quad (4)$$

is a RIGHT STROPHOID.

For an INVERSION CENTER at the FOCUS, the INVERSE CURVE

$$x = ae = \frac{k \cos t(1 - e \cos t)}{a(\cos t - e)^2} \quad (5)$$

$$y = \frac{\sqrt{e^2 - 1} k \sin(2t)}{2a(\cos t - e)^2} \quad (6)$$

is a LIMAÇON, where  $e$  is the ECCENTRICITY.

For a HYPERBOLA with  $a = \sqrt{3}b$  and INVERSION CENTER at the VERTEX, the INVERSE CURVE

$$x = b + \frac{2k \cos t(\sqrt{3} - \cos t)}{b[9 - 4\sqrt{3} \cos t + \cos(2t) - 2 \sin(2t)]} \quad (7)$$

$$y = b + \frac{k(\tan t - 1)}{b[(\sqrt{3} \sec t - 1)^2 + (\tan t - 1)^2]} \quad (8)$$

is a MACLAURIN TRISECTRIX.

## Hyperbolic Cosine

The hyperbolic cosine is defined as

$$\cosh x \equiv \frac{1}{2}(e^x + e^{-x}).$$

This function describes the shape of a hanging cable, known as the CATENARY.

## Hyperbolic Cotangent

The hyperbolic cotangent is defined as

$$\coth x \equiv \frac{e^x + e^{-x}}{e^x - e^{-x}} = \frac{e^{2x} + 1}{e^{2x} - 1}.$$

Its LAURENT SERIES is

$$\coth x = \frac{1}{x} + \frac{1}{3}x - \frac{1}{45}x^3 + \dots$$

### Hyperbolic Fixed Point (Map)

A FIXED POINT of a LINEAR TRANSFORMATION (MAP) for which the rescaled variables satisfy

$$(\delta - \alpha)^2 + 4\beta\gamma > 0.$$

see also ELLIPTIC FIXED POINT (MAP), LINEAR TRANSFORMATION, PARABOLIC FIXED POINT

### Hyperbolic Functions

The hyperbolic functions  $\sinh$ ,  $\cosh$ ,  $\tanh$ ,  $\operatorname{csch}$ ,  $\operatorname{sech}$ ,  $\operatorname{coth}$  (HYPERBOLIC SINE, HYPERBOLIC COSINE, etc.) share many properties with the corresponding CIRCULAR FUNCTIONS. The hyperbolic functions arise in many problems of mathematics and mathematical physics in which integrals involving  $\sqrt{1+x^2}$  arise (whereas the CIRCULAR FUNCTIONS involve  $\sqrt{1-x^2}$ ).

For instance, the HYPERBOLIC SINE arises in the gravitational potential of a cylinder and the calculation of the Roche limit. The HYPERBOLIC COSINE function is the shape of a hanging cable (the so-called CATENARY). The HYPERBOLIC TANGENT arises in the calculation of magnetic moment and rapidity of special relativity. All three appear in the Schwarzschild metric using external isotropic Kruskal coordinates in general relativity. The HYPERBOLIC SECANT arises in the profile of a laminar jet. The HYPERBOLIC COTANGENT arises in the Langevin function for magnetic polarization.

The hyperbolic functions are defined by

$$\sinh z \equiv \frac{e^z - e^{-z}}{2} = -\sinh(-z) \quad (1)$$

$$\cosh z \equiv \frac{e^z + e^{-z}}{2} = \cosh(-z) \quad (2)$$

$$\tanh z \equiv \frac{e^z - e^{-z}}{e^z + e^{-z}} = \frac{e^{2z} - 1}{e^{2z} + 1} \quad (3)$$

$$\operatorname{csch} z \equiv \frac{2}{e^z - e^{-z}} \quad (4)$$

$$\operatorname{sech} z \equiv \frac{2}{e^z + e^{-z}} \quad (5)$$

$$\operatorname{coth} z \equiv \frac{e^z + e^{-z}}{e^z - e^{-z}} = \frac{e^{2z} + 1}{e^{2z} - 1}. \quad (6)$$

For purely IMAGINARY arguments,

$$\sinh(iz) = i \sin z \quad (7)$$

$$\cosh(iz) = \cos z. \quad (8)$$

The hyperbolic functions satisfy many identities analogous to the trigonometric identities (which can be inferred using OSBORNE'S RULE) such as

$$\cosh^2 x - \sinh^2 x = 1 \quad (9)$$

$$\cosh x + \sinh x = e^x \quad (10)$$

$$\cosh x - \sinh x = e^{-x}. \quad (11)$$

See also Beyer (1987, p. 168). Some half-angle FORMULAS are

$$\tanh\left(\frac{z}{2}\right) = \frac{\sinh x + i \sin y}{\cosh x + \cos y} \quad (12)$$

$$\operatorname{coth}\left(\frac{z}{2}\right) = \frac{\sinh x - i \sin y}{\cosh x - \cos y}. \quad (13)$$

Some double-angle FORMULAS are

$$\sinh(2x) = 2 \sinh x \cosh x \quad (14)$$

$$\cosh(2x) = 2 \cosh^2 x - 1 = 1 + 2 \sinh^2 x. \quad (15)$$

Identities for COMPLEX arguments include

$$\sinh(x + iy) = \sinh x \cos y + i \cosh x \sin y \quad (16)$$

$$\cosh(x + iy) = \cosh x \cos y + i \sinh x \sin y. \quad (17)$$

The ABSOLUTE SQUARES for COMPLEX arguments are

$$|\sinh(z)|^2 = \sinh^2 x + \sin^2 y \quad (18)$$

$$|\cosh(z)|^2 = \sinh^2 x + \cos^2 y. \quad (19)$$

Integrals involving hyperbolic functions include

$$\begin{aligned} \int \frac{dx}{x\sqrt{a+bx}} &= \ln \left| \frac{\sqrt{a+bx} - \sqrt{a}}{\sqrt{a+bx} + \sqrt{a}} \right| \\ &= \ln \left| \frac{(\sqrt{a+bx} - \sqrt{a})^2}{(a+bx) - a} \right| \\ &= \ln \left| \frac{(a+bx) - 2\sqrt{a(a+bx)} + a}{bx} \right|. \end{aligned} \quad (20)$$

If  $b > 0$ , then

$$\begin{aligned} \int \frac{dx}{x\sqrt{a+bx}} &= \ln \left| \frac{2a+bx - 2\sqrt{a(a+bx)}}{bx} \right| \\ &= \ln \left| \left( \frac{2a}{bx} + 1 \right) - 2\sqrt{\frac{a}{bx} \left( \frac{a}{bx} + 1 \right)} \right|. \end{aligned} \quad (21)$$

Let  $z \equiv 2a/bx + 1$ , and  $a/bx = (z-1)/2$  and

$$\begin{aligned} \int \frac{dx}{x\sqrt{a+bx}} &= \ln \left[ z - 2\sqrt{\frac{1}{2}(z-1)\frac{1}{2}(z+1)} \right] \\ &= \ln \left[ z - \sqrt{(z-1)(z+1)} \right] \\ &= \ln \left( z - \sqrt{z^2 - 1} \right) = \cosh^{-1}(z) \\ &= \cosh^{-1} \left( 1 + \frac{2a}{bx} \right) \\ &= 2 \tanh \left( -\sqrt{\frac{a}{a+bx}} \right). \end{aligned} \quad (22)$$

see also HYPERBOLIC COSECANT, HYPERBOLIC COSINE, HYPERBOLIC COTANGENT, GENERALIZED HYPERBOLIC FUNCTIONS, HYPERBOLIC INVERSE FUNCTIONS, HYPERBOLIC SECANT, HYPERBOLIC SINE, HYPERBOLIC TANGENT, HYPERBOLIC INVERSE FUNCTIONS, OSBORNE'S RULE

**Hyperbolic Geometry**

A NON-EUCLIDEAN GEOMETRY, also called LOBACHEVSKY-BOLYAI-GAUSS GEOMETRY, having constant SECTIONAL CURVATURE  $-1$ . This GEOMETRY satisfies all of EUCLID'S POSTULATES *except* the PARALLEL POSTULATE, which is modified to read: For any infinite straight LINE  $L$  and any POINT  $P$  not on it, there are *many other* infinitely extending straight LINES that pass through  $P$  and which do not intersect  $L$ .

In hyperbolic geometry, the sum of ANGLES of a TRIANGLE is less than  $180^\circ$ , and TRIANGLES with the same angles have the same areas. Furthermore, not all TRIANGLES have the same ANGLE sum (c.f. the AAA THEOREM for TRIANGLES in Euclidean 2-space). The best-known example of a hyperbolic space are SPHERES in Lorentzian 4-space. The POINCARÉ HYPERBOLIC DISK is a hyperbolic 2-space. Hyperbolic geometry is well understood in 2-D, but not in 3-D.

Geometric models of hyperbolic geometry include the KLEIN-BELTRAMI MODEL, which consists of an OPEN DISK in the Euclidean plane whose open chords correspond to hyperbolic lines. A 2-D model is the POINCARÉ HYPERBOLIC DISK. Felix Klein constructed an analytic hyperbolic geometry in 1870 in which a POINT is represented by a pair of REAL NUMBERS  $(x_1, x_2)$  with

$$x_1^2 + x_2^2 < 1$$

(i.e., points of an OPEN DISK in the COMPLEX PLANE) and the distance between two points is given by

$$d(x, X) = a \cosh^{-1} \left[ \frac{1 - x_1 X_1 - x_2 X_2}{\sqrt{1 - x_1^2 - x_2^2} \sqrt{1 - X_1^2 - X_2^2}} \right].$$

The geometry generated by this formula satisfies all of EUCLID'S POSTULATES except the fifth. The METRIC of this geometry is given by the CAYLEY-KLEIN-HILBERT METRIC,

$$\begin{aligned} g_{11} &= \frac{a^2(1 - x_2^2)}{(1 - x_1^2 - x_2^2)^2} \\ g_{12} &= \frac{a^2 x_1 x_2}{(1 - x_1^2 - x_2^2)^2} \\ g_{22} &= \frac{a^2(1 - x_1^2)}{(1 - x_1^2 - x_2^2)^2}. \end{aligned}$$

Hilbert extended the definition to general bounded sets in a EUCLIDEAN SPACE.

**Hyperbolic Knot**

A hyperbolic knot is a KNOT that has a complement that can be given a metric of constant curvature  $-1$ . The only KNOTS which are not hyperbolic are TORUS KNOTS and SATELLITE KNOTS (including COMPOSITE KNOTS), as proved by Thurston in 1978. Therefore, all but six of the PRIME KNOTS with 10 or fewer crossings are hyperbolic. The exceptions with nine or fewer crossings are 03<sub>001</sub> (the(3,2)-TORUS KNOT), 05<sub>001</sub>, 07<sub>001</sub>, 08<sub>019</sub> (the (4,3)-TORUS KNOT), and 09<sub>001</sub>.

Almost all hyperbolic knots can be distinguished by their hyperbolic volumes (exceptions being 05<sub>002</sub> and a certain 12-crossing knot; see Adams 1994, p. 124). It has been conjectured that the smallest hyperbolic volume is 2.0298..., that of the FIGURE-OF-EIGHT KNOT.

MUTANT KNOTS have the same hyperbolic knot volume.

**Hyperbolic Lemniscate Function**

By analogy with the LEMNISCATE FUNCTIONS, hyperbolic lemniscate functions can also be defined

$$\operatorname{arcsinhlemn} x \equiv \int_0^x (1+t^4)^{1/2} dt \quad (1)$$

$$\operatorname{arccoshlemn} x \equiv \int_x^1 (1+t^4)^{1/2} dt. \quad (2)$$

Let  $0 \leq \theta \leq \pi/2$  and  $0 \leq v \leq 1$ , and write

$$\frac{\theta\mu}{2} = \int_0^v \frac{dt}{\sqrt{1+t^2}}, \quad (3)$$

where  $\mu$  is the constant obtained by setting  $\theta = \pi/2$  and  $v = 1$ . Then

$$\mu = \frac{2}{\pi} K\left(\frac{1}{\sqrt{2}}\right), \quad (4)$$

where  $K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and Ramanujan showed

$$2 \tan^{-1} v = \theta + \sum_{n=1}^{\infty} \frac{\sin(2n\theta)}{n \cosh(n\pi)}, \quad (5)$$

$$\frac{1}{8}\pi - \frac{1}{2} \tan^{-1}(v^2) = \sum_{n=0}^{\infty} \frac{(-1)^n \cos[(2n+1)\theta]}{(2n+1) \cosh[\frac{1}{2}(2n+1)\pi]} \quad (6)$$

and

$$\ln\left(\frac{1+v}{1-v}\right) = \ln[\tan(\frac{1}{4}\pi + \frac{1}{2}\theta)] + 4 \sum_{n=0}^{\infty} \frac{(-1)^n \sin[(2n+1)\theta]}{(2n+1)[e^{(2n+1)\pi} - 1]} \quad (7)$$

(Berndt 1994).

**Hyperbolic Map**

A linear MAP  $\mathbb{R}^n$  is hyperbolic if none of its EIGENVALUES have modulus 1. This means that  $\mathbb{R}^n$  can be written as a direct sum of two  $A$ -invariant SUBSPACES  $E^s$  and  $E^u$  (where  $s$  stands for stable and  $u$  for unstable). This means that there exist constants  $C > 0$  and  $0 < \lambda < 1$  such that

$$\|A^n v\| \leq C\lambda^n \|v\| \quad \text{if } v \in E^s$$

$$\|A^{-n} v\| \leq C\lambda^n \|v\| \quad \text{if } v \in E^u$$

for  $n = 0, 1, \dots$

see also PESIN THEORY

**Hyperbolic Metric**

The METRIC for the POINCARÉ HYPERBOLIC DISK, a model for HYPERBOLIC GEOMETRY. The hyperbolic metric is invariant under conformal maps of the disk onto itself.

**Hyperbolic Octahedron**

A hyperbolic version of the Euclidean OCTAHEDRON, which is a special case of the ASTROIDAL ELLIPSOID with  $a = b = c = 1$ . It is given by the parametric equations

$$\begin{aligned} x &= (\cos u \cos v)^3 \\ y &= (\sin u \cos v)^3 \\ z &= \sin^3 v \end{aligned}$$

for  $u \in [-\pi/2, \pi/2]$  and  $v \in [-\pi, \pi]$ .

**Hyperbolic Paraboloid**

A QUADRATIC SURFACE given by the Cartesian equation

$$z = \frac{y^2}{b^2} - \frac{x^2}{a^2} \quad (1)$$

(left figure). This form has parametric equations

$$x(u, v) = a(u + v) \quad (2)$$

$$y(u, v) = \pm bv \quad (3)$$

$$z(u, v) = u^2 + 2uv \quad (4)$$

(Gray 1993, p. 336). An alternative form is

$$z = xy \quad (5)$$

(right figure; Fischer 1986), which has parametric equations

$$x(u, v) = u \quad (6)$$

$$y(u, v) = v \quad (7)$$

$$z(u, v) = uv. \quad (8)$$

## Hyperbolic Partial Differential Equation

A PARTIAL DIFFERENTIAL EQUATION of second-order, i.e., one of the form

$$Au_{xx} + 2Bu_{xy} + Cu_{yy} + Du_x + Eu_y + F = 0, \quad (1)$$

is called hyperbolic if the MATRIX

$$Z \equiv \begin{bmatrix} A & B \\ B & C \end{bmatrix} \quad (2)$$

satisfies  $\det(Z) < 0$ . The WAVE EQUATION is an example of a hyperbolic partial differential equation. Initial-boundary conditions are used to give

$$u(x, y, t) = g(x, y, t) \quad \text{for } x \in \partial\Omega, t > 0 \quad (3)$$

$$u(x, y, 0) = v_0(x, y) \quad \text{in } \Omega \quad (4)$$

$$u_t(x, y, 0) = v_1(x, y) \quad \text{in } \Omega, \quad (5)$$

where

$$u_{xy} = f(u_x, u_t, x, y) \quad (6)$$

holds in  $\Omega$ .

## Hyperbolic Plane

In the hyperbolic plane  $\mathbb{H}^2$ , a pair of LINES can be PARALLEL (diverging from one another in one direction and intersecting at an IDEAL POINT at infinity in the other), can intersect, or can be HYPERPARALLEL (diverge from each other in both directions).

see also EUCLIDEAN PLANE, RIGID MOTION

## Hyperbolic Point

A point  $\mathbf{p}$  on a REGULAR SURFACE  $M \in \mathbb{R}^3$  is said to be hyperbolic if the GAUSSIAN CURVATURE  $K(\mathbf{p}) < 0$  or equivalently, the PRINCIPAL CURVATURES  $\kappa_1$  and  $\kappa_2$ , have opposite signs.

## Hyperbolic Polyhedron

A POLYHEDRON in a HYPERBOLIC GEOMETRY.

see HYPERBOLIC CUBE, HYPERBOLIC DODECAHEDRON, HYPERBOLIC OCTAHEDRON, HYPERBOLIC TETRAHEDRON

## Hyperbolic Rotation

Also known as the LORENTZ TRANSFORMATION or PROCRUSTIAN STRETCH. Leaves each branch of the HYPERBOLA  $x'y' = xy$  invariant and transforms CIRCLES into ELLIPSES with the same AREA.

$$x' = \mu^{-1}x$$

$$y' = \mu y.$$

## Hyperbolic Rotation (Crossed)

Exchanges branches of the HYPERBOLA  $x'y' = xy$ .

$$x' = \mu^{-1}x$$

$$y' = -\mu y.$$

## Hyperbolic Secant

The hyperbolic secant is defined as

$$\operatorname{sech} x \equiv \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}}.$$

It has a MAXIMUM at  $x = 0$  and inflection points at  $x = \pm \operatorname{sech}^{-1}(1/\sqrt{2}) \approx 0.881374$ .

**Hyperbolic Spiral Inverse Curve**

Taking the pole as the INVERSION CENTER, the HYPERBOLIC SPIRAL inverts to ARCHIMEDES' SPIRAL

$$r = a\theta.$$

**Hyperbolic Spiral Roulette**

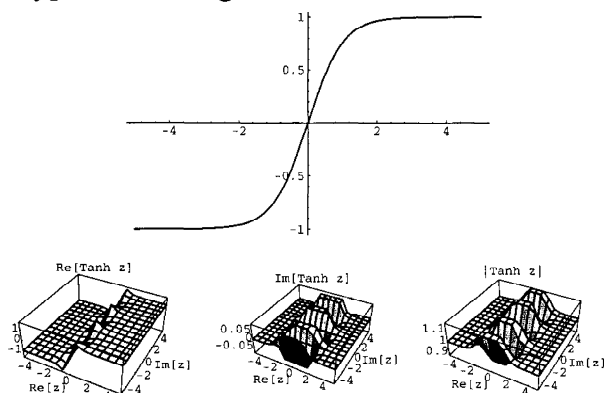

The ROULETTE of the pole of a HYPERBOLIC SPIRAL rolling on a straight line is a TRACTRIX.

**Hyperbolic Substitution**

A substitution which can be used to transform integrals involving square roots into a more tractable form.

Form	Substitution
$\sqrt{x^2 + a^2}$	$x = a \sinh u$
$\sqrt{x^2 - a^2}$	$x = a \cosh u$

see also TRIGONOMETRIC SUBSTITUTION

**Hyperbolic Tangent**

By way of analogy with the usual TANGENT

$$\tan x \equiv \frac{\sin x}{\cos x},$$

the hyperbolic tangent is defined as

$$\tanh x \equiv \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}} = \frac{e^{2x} - 1}{e^{2x} + 1},$$

where  $\sinh x$  is the HYPERBOLIC SINE and  $\cosh x$  is the HYPERBOLIC COSINE. The hyperbolic tangent can be written using a CONTINUED FRACTION as

$$\tanh x = \frac{x}{1 + \frac{x^2}{3 + \frac{x^2}{5 + \dots}}}$$

**Hyperbolic Umbilic Catastrophe**

A CATASTROPHE which can occur for three control factors and two behavior axes.

see also ELLIPTIC UMBILIC CATASTROPHE

**Hyperboloid**

A QUADRATIC SURFACE which may be one- or two-sheeted.

The one-sheeted circular hyperboloid is a doubly RULED SURFACE. When oriented along the  $z$ -AXIS, the one-sheeted circular hyperboloid has CARTESIAN COORDINATES equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1, \quad (1)$$

and parametric equation

$$x = a\sqrt{1+u^2} \cos v \quad (2)$$

$$y = a\sqrt{1+u^2} \sin v \quad (3)$$

$$z = cu \quad (4)$$

for  $v \in [0, 2\pi)$  (left figure). Other parameterizations include

$$x(u, v) = a(\cos u \mp v \sin u) \quad (5)$$

$$y(u, v) = a(\sin u \pm v \cos u) \quad (6)$$

$$z(u, v) = \pm cv, \quad (7)$$

(middle figure), or

$$x(u, v) = a \cosh v \cos u \quad (8)$$

$$y(u, v) = a \cosh v \sin u \quad (9)$$

$$z(u, v) = c \sinh v \quad (10)$$

(right figure). An obvious generalization gives the one-sheeted ELLIPTIC HYPERBOLOID.

A two-sheeted circular hyperboloid oriented along the  $z$ -AXIS has CARTESIAN COORDINATES equation

$$\frac{x^2}{a^2} + \frac{y^2}{a^2} - \frac{z^2}{c^2} = -1. \quad (11)$$

The parametric equations are

$$x = a \sinh u \cos v \quad (12)$$

$$y = a \sinh u \sin v \quad (13)$$

$$z = \pm c \cosh u \quad (14)$$

for  $v \in [0, 2\pi)$ . Note that the plus and minus signs in  $z$  correspond to the upper and lower sheets. The two-sheeted circular hyperboloid oriented along the  $x$ -AXIS has Cartesian equation

$$\frac{x^2}{a^2} - \frac{y^2}{a^2} - \frac{z^2}{c^2} = 1 \quad (15)$$

and parametric equations

$$x = \pm a \cosh u \cosh v \quad (16)$$

$$y = a \sinh u \cosh v \quad (17)$$

$$z = c \sinh v \quad (18)$$

(Gray 1993, p. 313). Again, an obvious generalization gives the two-sheeted ELLIPTIC HYPERBOLOID.

The SUPPORT FUNCTION of the hyperboloid of one sheet

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \quad (19)$$

is

$$h = \left( \frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4} \right)^{-1/2}, \quad (20)$$

and the GAUSSIAN CURVATURE is

$$K = -\frac{h^4}{a^2 b^2 c^2}. \quad (21)$$

The SUPPORT FUNCTION of the hyperboloid of two sheets

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} - \frac{z^2}{c^2} = 1 \quad (22)$$

is

$$h = \left( \frac{x^2}{a^4} - \frac{y^2}{b^4} + \frac{z^2}{c^4} \right)^{-1/2}, \quad (23)$$

and the GAUSSIAN CURVATURE is

$$K = \frac{h^4}{a^2 b^2 c^2} \quad (24)$$

(Gray 1993, pp. 296–297).

see also CATENOID, ELLIPSOID, ELLIPTIC HYPERBOLOID, HYPERBOLOID EMBEDDING, PARABOLOID, RULED SURFACE

#### References

- Fischer, G. (Ed.). Plates 67 and 69 in *Mathematische Modelle/Mathematical Models, Bildband/Photograph Volume*. Braunschweig, Germany: Vieweg, pp. 62 and 64, 1986.  
 Gray, A. "The Hyperboloid of Revolution." §18.5 in *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 296–297, 311–314, and 369–370, 1993.

#### Hyperboloid Embedding

A 4-HYPERBOLOID has NEGATIVE CURVATURE, with

$$R^2 = x^2 + y^2 + z^2 - w^2 \quad (1)$$

$$2x \frac{dx}{dw} + 2y \frac{dy}{dw} + 2z \frac{dz}{dw} - 2w = 0. \quad (2)$$

Since

$$\mathbf{r} \equiv x\hat{\mathbf{x}} + y\hat{\mathbf{y}} + z\hat{\mathbf{z}}, \quad (3)$$

$$dw = \frac{x dx + y dy + z dz}{w} = \frac{\mathbf{r} \cdot d\mathbf{r}}{\sqrt{r^2 - R^2}}. \quad (4)$$

To stay on the surface of the HYPERBOLOID,

$$\begin{aligned} ds^2 &= dx^2 + dy^2 + dz^2 - dw^2 \\ &= dx^2 + dy^2 + dz^2 - \frac{r^2 dr^2}{r^2 - R^2} \\ &= dr^2 + r^2 d\Omega^2 + \frac{dr^2}{1 - \frac{R^2}{r^2}}. \end{aligned} \quad (5)$$

### Hypercomplex Number

A number having properties departing from those of the REAL and COMPLEX NUMBERS. The most common examples are BIQUATERNIONS, EXTERIOR ALGEBRAS, GROUP algebras, MATRICES, OCTONIONS, and QUATERNIONS.

#### References

van der Waerden, B. L. *A History of Algebra from al-Khwarizmi to Emmy Noether*. New York: Springer-Verlag, pp. 177–217, 1985.

### Hypercube

The generalization of a 3-CUBE to  $n$ -D, also called a MEASURE POLYTOPE. It is a regular POLYTOPE with mutually PERPENDICULAR sides, and is therefore an ORTHOTOPE. It is denoted  $\gamma_n$  and has SCHLÄFLI SYMBOL  $\{4, 3, 3\}$ . The number of  $k$ -cubes contained in an  $n$ -cube can be found from the COEFFICIENTS of  $(2k+1)^n$ .

The 1-hypercube is a LINE SEGMENT, the 2-hypercube is the SQUARE, and the 3-hypercube is the CUBE. The hypercube in  $\mathbb{R}^4$ , called a TESSERACT, has the SCHLÄFLI SYMBOL  $\{4, 3, 3\}$  and VERTICES  $(\pm 1, \pm 1, \pm 1, \pm 1)$ . The above figures show two visualizations of the TESSERACT. The figure on the left is a projection of the TESSERACT in 3-space (Gardner 1977), and the figure on the right is the GRAPH of the TESSERACT symmetrically projected into the PLANE (Coxeter 1973). A TESSERACT has 16 VERTICES, 32 EDGES, four SQUARES, and eight CUBES. *see also* CROSS POLYTOPE, CUBE, HYPERSPHERE, ORTHOTOPE, PARALLELEPIPED, POLYTOPE, SIMPLEX, TESSERACT

### Hyperdeterminant

A technically defined extension of the ordinary DETERMINANT to "higher dimensional" HYPERMATRICES. Cayley (1845) originally coined the term, but subsequently used it to refer to an ALGEBRAIC INVARIANT of a multilinear form. The hyperdeterminant of the  $2 \times 2 \times 2$  HYPERMATRIX  $A = a_{ijk}$  (for  $i, j, k = 0, 1$ ) is given by

$$\begin{aligned} \det(A) &= (a_{000}^2 a_{111}^2 + a_{001}^2 a_{110}^2 + a_{010}^2 a_{101}^2 + a_{011}^2 a_{100}^2) \\ &\quad - 2(a_{000} a_{001} a_{110} a_{111} + a_{000} a_{010} a_{101} a_{111} + a_{000} a_{011} a_{100} a_{111} \\ &\quad + a_{001} a_{010} a_{101} a_{110} + a_{001} a_{011} a_{110} a_{100} + a_{010} a_{011} a_{101} a_{100}) \\ &\quad + 4(a_{000} a_{011} a_{101} a_{110} + a_{001} a_{010} a_{100} a_{111}). \end{aligned}$$

The above hyperdeterminant vanishes IFF the following system of equations in six unknowns has a nontrivial solution,

$$\begin{aligned} a_{000}x_0y_0 + a_{010}x_0y_1 + a_{100}x_1y_0 + a_{110}x_1y_1 &= 0 \\ a_{001}x_0y_0 + a_{011}x_0y_1 + a_{101}x_1y_0 + a_{111}x_1y_1 &= 0 \\ a_{000}x_0z_0 + a_{001}x_0z_1 + a_{100}x_1z_0 + a_{101}x_1z_1 &= 0 \\ a_{010}x_0z_0 + a_{011}x_0z_1 + a_{110}x_1z_0 + a_{111}x_1z_1 &= 0 \\ a_{000}y_0z_0 + a_{001}y_0z_1 + a_{010}y_1z_0 + a_{011}y_1z_1 &= 0 \\ a_{100}y_0z_0 + a_{101}y_0z_1 + a_{110}y_1z_0 + a_{111}y_1z_1 &= 0. \end{aligned}$$

### Hyperellipse

$$y^{n/m} + c \left| \frac{x}{a} \right|^{n/m} - c = 0,$$

with  $n/m > 2$ . If  $n/m < 2$ , the curve is a HYPOELLIPSE. *see also* ELLIPSE, HYPOELLIPSE, SUPERELLIPSE

### Hyperelliptic Function

*see* ABELIAN FUNCTION

**Hyperelliptic Integral**

see ABELIAN INTEGRAL

**Hyperfactorial**

The function defined by

$$H(n) \equiv K(n+1) \equiv 1^1 2^2 3^3 \cdots n^n,$$

where  $K$  is the  $K$ -FUNCTION and the first few values for  $n = 1, 2, \dots$  are 1, 4, 108, 27648, 86400000, 4031078400000, 3319766398771200000, ... (Sloane's A002109), and these numbers are called hyperfactorials by Sloane and Plouffe (1995).

Sloane, N. J. A. Sequence A002109/M3706 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**Hypergeometric Differential Equation**

$$x(x-1)\frac{d^2y}{dx^2} + [(1+\alpha+\beta)x - \gamma]\frac{dy}{dx} + \alpha\beta y = 0.$$

It has REGULAR SINGULAR POINTS at 0, 1, and  $\infty$ . Every ORDINARY DIFFERENTIAL EQUATION of second-order with at most three REGULAR SINGULAR POINTS can be transformed into the hypergeometric differential equation.

**Hypergeometric Distribution**

Let there be  $n$  ways for a successful and  $m$  ways for an unsuccessful trial out of a total of  $n+m$  possibilities. Take  $N$  samples and let  $x_i$  equal 1 if selection  $i$  is successful and 0 if it is not. Let  $x$  be the total number of successful selections,

$$x \equiv \sum_{i=1}^N x_i. \quad (1)$$

The probability of  $i$  successful selections is then

$$\begin{aligned} P(x=i) &= \frac{[\# \text{ ways for } i \text{ successes}][\# \text{ ways for } N-i \text{ successes}]}{[\text{total number of ways to select}]} \\ &= \frac{\binom{n}{i} \binom{m}{N-i}}{\binom{n+m}{N}} = \frac{\frac{n!}{i!(n-i)!} \frac{m!}{(m+i-N)!(N-i)!}}{\frac{(n+m)!}{N!(N-n-m)!}} \\ &= \frac{n!m!N!(N-m-n)!}{i!(n-i)!(m+i-N)!(N-i)!(n+m)!}. \quad (2) \end{aligned}$$

The  $i$ th selection has an equal likelihood of being in any trial, so the fraction of acceptable selections  $p$  is

$$p \equiv \frac{n}{n+m} \quad (3)$$

$$P(x_i=1) = \frac{n}{n+m} \equiv p. \quad (4)$$

The expectation value of  $x$  is

$$\begin{aligned} \mu \equiv \langle x \rangle &= \left\langle \sum_{i=1}^N x_i \right\rangle = \sum_{i=1}^N \langle x_i \rangle \\ &= \sum_{i=1}^N \frac{n}{n+m} = \frac{nN}{n+m} = Np. \quad (5) \end{aligned}$$

The VARIANCE is

$$\text{var}(x) \equiv \sum_{i=1}^N \text{var}(x_i) + \sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \text{cov}(x_i, x_j). \quad (6)$$

Since  $x_i$  is a BERNOULLI variable,

$$\begin{aligned} \text{var}(x_i) &= p(1-p) = \frac{n}{n+m} \left(1 - \frac{n}{n+m}\right) \\ &= \frac{n}{n+m} \left(1 - \frac{n}{n+m}\right) \\ &= \frac{n}{n+m} \left(\frac{n+m-n}{n+m}\right) = \frac{nm}{(n+m)^2}, \quad (7) \end{aligned}$$

so

$$\sum_{i=1}^N \text{var}(x_i) = \frac{Nnm}{(n+m)^2}. \quad (8)$$

For  $i < j$ , the COVARIANCE is

$$\text{cov}(x_i, x_j) = \langle x_i x_j \rangle - \langle x_i \rangle \langle x_j \rangle. \quad (9)$$

The probability that both  $i$  and  $j$  are successful for  $i \neq j$  is

$$\begin{aligned} P(x_i=1, x_j=1) &= P(x_i=1)P(x_j=1|x_i=1) \\ &= \frac{n}{n+m} \frac{n-1}{n+m-1} \\ &= \frac{n(n-1)}{(n+m)(n+m-1)}. \quad (10) \end{aligned}$$

But since  $x_i$  and  $x_j$  are random BERNOULLI variables (each 0 or 1), their product is also a BERNOULLI variable. In order for  $x_i x_j$  to be 1, both  $x_i$  and  $x_j$  must be 1,

$$\begin{aligned} \langle x_i x_j \rangle &= P(x_i x_j=1) = P(x_i=1, x_j=1) \\ &= \frac{n}{n+m} \frac{n-1}{n+m-1} \\ &= \frac{n(n-1)}{(n+m)(n+m-1)}. \quad (11) \end{aligned}$$

Combining (11) with

$$\langle x_i \rangle \langle x_j \rangle = \frac{n}{n+m} \frac{n}{n+m} = \frac{n^2}{(n+m)^2}, \quad (12)$$

gives

$$\begin{aligned} \text{cov}(x_i, x_j) &= \frac{(n+m)(n^2-n) - n^2(n+m-1)}{(n+m)^2(n+m-1)} \\ &= \frac{n^3 + mn^2 - n^2 - mn - n^3 - n^2m + n^2}{(n+m)^2(n+m-1)} \\ &= -\frac{mn}{(n+m)^2(n+m-1)}. \end{aligned} \quad (13)$$

There are a total of  $N^2$  terms in a double summation over  $N$ . However,  $i = j$  for  $N$  of these, so there are a total of  $N^2 - N = N(N-1)$  terms in the COVARIANCE summation

$$\sum_{i=1}^N \sum_{\substack{j=1 \\ j \neq i}}^N \text{cov}(x_i, x_j) = -\frac{N(N-1)mn}{(n+m)^2(n+m-1)}. \quad (14)$$

Combining equations (6), (8), (11), and (14) gives the VARIANCE

$$\begin{aligned} \text{var}(x) &= \frac{Nmn}{(n+m)^2} - \frac{N(N-1)mn}{(n+m)^2(n+m-1)} \\ &= \frac{Nmn}{(n+m)^2} \left(1 - \frac{N-1}{n+m-1}\right) \\ &= \frac{Nmn}{(n+m)^2} \left(\frac{N+m-1-N+1}{n+m-1}\right) \\ &= \frac{Nmn(n+m-N)}{(n+m)^2(n+m-1)}, \end{aligned} \quad (15)$$

so the final result is

$$\langle x \rangle = Np \quad (16)$$

and, since

$$1-p = \frac{m}{n+m} \quad (17)$$

and

$$np(1-p) = \frac{mn}{(n+m)^2}, \quad (18)$$

we have

$$\begin{aligned} \sigma^2 &= \text{var}(x) = Np(1-p) \left(1 - \frac{N-1}{n+m-1}\right) \\ &= \frac{mnN(m+n-N)}{(m+n)^2(m+n-1)}. \end{aligned} \quad (19)$$

The SKEWNESS is

$$\begin{aligned} \gamma_1 &= \frac{q-p}{\sqrt{npq}} \sqrt{\frac{N-1}{N-m}} \left(\frac{N-2n}{N-2}\right) \\ &= \frac{(m-n)(m+n-2N)}{m+n-2} \sqrt{\frac{m+n-1}{mnN(m+n-N)}}, \end{aligned} \quad (20)$$

and the KURTOSIS

$$\gamma_2 = \frac{F(m, n, N)}{mnN(-3+m+n)(-2+m+n)(-m-n+N)}, \quad (21)$$

where

$$\begin{aligned} F(m, n, N) &= m^3 - m^5 + 3m^2n - 6m^3n + m^4n + 3mn^2 \\ &\quad - 12m^2n^2 + 8m^3n^2 + n^3 - 6mn^3 + 8m^2n^3 \\ &\quad + mn^4 - n^5 - 6m^3N + 6m^4N + 18m^2nN \\ &\quad - 6m^3nN + 18mn^2N - 24m^2n^2N - 6n^3N \\ &\quad - 6mn^3N + 6n^4N + 6m^2N^2 - 6m^3N^2 \\ &\quad - 24mnN^2 + 12m^2nN^2 + 6n^2N^2 \\ &\quad + 12mn^2N^2 - 6n^3N^2. \end{aligned} \quad (22)$$

The GENERATING FUNCTION is

$$\phi(t) = \frac{\binom{m}{N}}{\binom{n+m}{N}} {}_2F_1(-N, -n; m-N+1; e^{it}), \quad (23)$$

where  ${}_2F_1(a, b; c; z)$  is the HYPERGEOMETRIC FUNCTION.

If the hypergeometric distribution is written

$$h_n(x, s) = \frac{\binom{np}{x} \binom{nq}{s-x}}{\binom{n}{s}}, \quad (24)$$

then

$$\sum_{x=0}^s h_n(x, s) u^x = A {}_2F_1(-s, -np; nq-s+1; u). \quad (25)$$

## Hypergeometric Function

A GENERALIZED HYPERGEOMETRIC FUNCTION  ${}_pF_q(a_1, \dots, a_p; b_1, \dots, b_q; x)$  is a function which can be defined in the form of a HYPERGEOMETRIC SERIES, i.e., a series for which the ratio of successive terms can be written

$$\frac{a_{k+1}}{a_k} = \frac{P(k)}{Q(k)} = \frac{(k+a_1)(k+a_2) \cdots (k+a_p)}{(k+b_1)(k+b_2) \cdots (k+b_q)(k+1)} x. \quad (1)$$

(The factor of  $k+1$  in the DENOMINATOR is present for historical reasons of notation.) The function  ${}_2F_1(a, b; c; x)$  corresponding to  $p=2$ ,  $q=1$  is the first hypergeometric function to be studied (and, in general, arises the most frequently in physical problems), and so is frequently known as "the" hypergeometric equation.

To confuse matters even more, the term "hypergeometric function" is less commonly used to mean CLOSED FORM.

The hypergeometric functions are solutions to the HYPERGEOMETRIC DIFFERENTIAL EQUATION, which has a REGULAR SINGULAR POINT at the ORIGIN. To derive the hypergeometric function based on the HYPERGEOMETRIC DIFFERENTIAL EQUATION, plug

$$y = \sum_{n=0}^{\infty} A_n z^n \quad (2)$$

$$y' = \sum_{n=0}^{\infty} n A_n z^{n-1} \quad (3)$$

$$y'' = \sum_{n=0}^{\infty} n(n-1) A_n z^{n-2} \quad (4)$$

into

$$z(1-z)y'' + [c - (a+b+1)z]y' - aby = 0 \quad (5)$$

to obtain

$$\begin{aligned} \sum_{n=0}^{\infty} n(n-1) A_n z^{n-1} - \sum_{n=0}^{\infty} n(n-1) A_n z^n \\ + c \sum_{n=0}^{\infty} n A_n z^{n-1} + (a+b+1) \sum_{n=0}^{\infty} n A_n z^n \\ - ab \sum_{n=0}^{\infty} A_n z^n = 0 \end{aligned} \quad (6)$$

$$\begin{aligned} \sum_{n=2}^{\infty} n(n-1) A_n z^{n-1} - \sum_{n=0}^{\infty} n(n-1) A_n z^n \\ + c \sum_{n=1}^{\infty} n A_n z^{n-1} - (a+b+1) \sum_{n=1}^{\infty} n A_n z^n \\ - ab \sum_{n=0}^{\infty} A_n z^n = 0 \end{aligned} \quad (7)$$

$$\begin{aligned} \sum_{n=0}^{\infty} (n+1) n A_{n+1} z^n - \sum_{n=0}^{\infty} n(n-1) A_n z^n \\ + c \sum_{n=0}^{\infty} (n+1) A_{n+1} z^n - (a+b+1) \sum_{n=0}^{\infty} n A_n z^n \\ - ab \sum_{n=0}^{\infty} A_n z^n = 0 \end{aligned} \quad (8)$$

$$\begin{aligned} \sum_{n=0}^{\infty} [n(n+1) A_{n+1} - n(n-1) A_n + c(n+1) A_{n+1} \\ - (a+b+1) n A_n - ab A_n] z^n = 0 \end{aligned} \quad (9)$$

$$\begin{aligned} \sum_{n=0}^{\infty} \{(n+1)(n+c) A_{n+1} \\ - [n(n-1+a+b+1) + ab] A_n\} z^n = 0 \end{aligned} \quad (10)$$

$$\begin{aligned} \sum_{n=0}^{\infty} \{(n+1)(n+c) A_{n+1} \\ - [n^2 + (a+b)n + ab] A_n\} z^n = 0, \end{aligned} \quad (11)$$

so

$$A_{n+1} = \frac{(n+a)(n+b)}{(n+1)(n+c)} A_n \quad (12)$$

and

$$y = A_0 \left[ 1 + \frac{ab}{1!c} z + \frac{a(a+1)b(b+1)}{2!c(c+1)} z^2 + \dots \right] \quad (13)$$

This is the regular solution and is denoted

$$\begin{aligned} {}_2F_1(a, b; c; z) = 1 + \frac{ab}{1!c} z + \frac{a(a+1)b(b+1)}{2!c(c+1)} z^2 + \dots \\ = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!}, \end{aligned} \quad (14)$$

where  $(a)_n$  are POCHHAMMER SYMBOLS. The hypergeometric series is convergent for REAL  $-1 < z < 1$ , and for  $z = \pm 1$  if  $c > a + b$ . The complete solution to the HYPERGEOMETRIC DIFFERENTIAL EQUATION is

$$y = A_2 {}_2F_1(a, b; c; z) + B z^{1-c} {}_2F_1(a+1-c, b+1-c; 2-c; z). \quad (15)$$

Derivatives are given by

$$\begin{aligned} \frac{d {}_2F_1(a, b; c; z)}{dz} &= \frac{ab}{c} {}_2F_1(a+1, b+1; c+1; z) \quad (16) \\ \frac{d^2 {}_2F_1(a, b; c; z)}{dz^2} &= \frac{a(a+1)b(b+1)}{c(c+1)} \\ &\quad \times {}_2F_1(a+2, b+2; c+2; z) \end{aligned} \quad (17)$$

(Magnus and Oberhettinger 1949, p. 8). An integral giving the hypergeometric function is

$${}_2F_1(a, b; c; z) = \frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)} \int_0^1 \frac{t^{b-1}(1-t)^{c-b-1}}{(1-tz)^a} dt \quad (18)$$

as shown by Euler in 1748.

A hypergeometric function can be written using EULER'S HYPERGEOMETRIC TRANSFORMATIONS

$$t \rightarrow t \quad (19)$$

$$t \rightarrow 1-t \quad (20)$$

$$t \rightarrow (1-z-tz)^{-1} \quad (21)$$

$$t \rightarrow \frac{1-t}{1-tz} \quad (22)$$

in any one of four equivalent forms

$${}_2F_1(a, b; c; z) = (1-z)^{-a} {}_2F_1(a, c-b; c; z/(z-1)) \quad (23)$$

$$= (1-z)^{-b} {}_2F_1(c-a, b; c; z/(z-1)) \quad (24)$$

$$= (1-z)^{c-a-b} {}_2F_1(c-a, c-b; c; z). \quad (25)$$

It can also be written as a linear combination

$$\begin{aligned} & {}_2F_1(a, b; c; z) \\ &= \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} {}_2F_1(a, b; a+b+1-c; 1-z) \\ &\quad + \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)} (1-z)^{c-a-b} \\ &\quad \times {}_2F_1(c-a, c-b; 1+c-a-b; 1-z). \end{aligned} \quad (26)$$

Kummer found all six solutions (not necessarily regular at the origin) to the HYPERGEOMETRIC DIFFERENTIAL EQUATION,

$$\begin{aligned} u_1(x) &= {}_2F_1(a, b; c; z) \\ u_2(x) &= {}_2F_1(a, b; a+b+1-c; 1-z) \\ u_3(x) &= z^{-a} {}_2F_1(a, a+1-c; a+1-b; 1/z) \\ u_4(x) &= z^{-b} {}_2F_1(b+1-c, b; b+1-a; 1/z) \\ u_5(x) &= z^{1-c} {}_2F_1(b+1-c, a+1-c; 2-c; z) \\ u_6(x) &= (1-z)^{c-a-b} {}_2F_1(c-a, c-b; c+1-a-b; 1-z). \end{aligned}$$

Applying EULER'S HYPERGEOMETRIC TRANSFORMATIONS to the Kummer solutions then gives all 24 possible forms which are solutions to the HYPERGEOMETRIC DIFFERENTIAL EQUATION

$$\begin{aligned} u_1^{(1)}(x) &= {}_2F_1(a, b; c; z) \\ u_1^{(2)}(x) &= (1-z)^{-a} {}_2F_1(a, c-b; c; z/(z-1)) \\ u_1^{(3)}(x) &= (1-z)^{-b} {}_2F_1(c-a, b; c; z/(z-1)) \\ u_1^{(4)}(x) &= (1-z)^{c-a-b} {}_2F_1(c-a, c-b; c; z) \\ u_2^{(1)}(x) &= {}_2F_1(a, b; a+b+1-c; 1-z) \\ u_2^{(2)}(x) &= z^{-a} {}_2F_1(a, a+1-c; a+b+1-c; 1-1/z) \\ u_2^{(3)}(x) &= z^{-b} {}_2F_1(b+1-c, b; a+b+1-c; 1-1/z) \\ u_2^{(4)}(x) &= z^{1-c} {}_2F_1(b+1-c, a+1-c; a+b+1-c; 1-z) \\ u_3^{(1)}(x) &= z^{-a} {}_2F_1(a, a+1-c; a+1-b; 1/z) \\ u_3^{(2)}(x) &= z^{-a}(1-1/z)^{-a} {}_2F_1(a, c-b; a+1-b; 1/(1-z)) \\ u_3^{(3)}(x) &= z^{-a}(1-1/z)^{c-a-1} \\ &\quad \times {}_2F_1(1-b, a+1-c; a+1-b; 1/(1-z)) \\ u_3^{(4)}(x) &= z^{-a}(1-1/z)^{c-a-b} {}_2F_1(1-b, c-b; a+1-b; 1/z) \\ u_4^{(1)}(x) &= z^{-b} {}_2F_1(b+1-c, b; b+1-a; 1/z) \\ u_4^{(2)}(x) &= z^{-b}(1-1/z)^{c-b-1} \\ &\quad \times {}_2F_1(b_1-c, 1-a; b+1-a; 1/(1-z)) \\ u_4^{(3)}(x) &= z^{-b}(1-1/z)^{-b} {}_2F_1(c-a, b; b+1-a; 1/(1-z)) \\ u_4^{(4)}(x) &= z^{-b}(1-1/z)^{c-a-b} {}_2F_1(c-a, 1-a; b+1-a; 1/z) \end{aligned}$$

$$\begin{aligned} u_5^{(1)}(x) &= z^{1-c} {}_2F_1(b+1-c, a+1-c; 2-c; z) \\ u_5^{(2)}(x) &= z^{1-c}(1-z)^{c-b-1} {}_2F_1(b+1-c, 1-a; 2-c; z/(z-1)) \\ u_5^{(3)}(x) &= z^{1-c}(1-z)^{c-a-1} {}_2F_1(1-b, a+1-c; 2-c; z/(z-1)) \\ u_5^{(4)}(x) &= z^{1-c}(1-z)^{c-a-b} {}_2F_1(1-b, 1-a; 2-c; z) \\ u_6^{(1)}(x) &= (1-z)^{c-a-b} {}_2F_1(c-a, c-b; c+1-a-b; 1-z) \\ u_6^{(2)}(x) &= z^{a-c}(1-z)^{c-a-b} \\ &\quad \times {}_2F_1(c-a, 1-a; c+1-a-b; 1-1/z) \\ u_6^{(3)}(x) &= z^{b-c}(1-z)^{c-a-b} \\ &\quad \times {}_2F_1(1-b, c-b; c+1-a-b; 1-1/z) \\ u_6^{(4)}(x) &= z^{c-a-b}(1-z)^{c-a-b} \\ &\quad \times {}_2F_1(1-b, 1-a; c+1-a-b; 1-z). \end{aligned}$$

Goursat (1881) gives many hypergeometric transformation FORMULAS, including several cubic transformation FORMULAS.

Many functions of mathematical physics can be expressed as special cases of the hypergeometric functions. For example,

$${}_2F_1(-l, l+1, 1; (1-z)/2) = P_l(z), \quad (27)$$

where  $P_l(z)$  is a LEGENDRE POLYNOMIAL.

$$(1+z)^n = {}_2F_1(-n, b; b; -z) \quad (28)$$

$$\ln(1+z) = z {}_2F_1(1, 1; 2; -z) \quad (29)$$

Complete ELLIPTIC INTEGRALS and the RIEMANN  $P$ -SERIES can also be expressed in terms of  ${}_2F_1(a, b; c; z)$ . Special values include

$$\begin{aligned} & {}_2F_1(a, b; a-b+1; -1) \\ &= 2^{-a} \sqrt{\pi} \frac{\Gamma(1+a+b)}{\Gamma(1+\frac{1}{2}a-b)\Gamma(\frac{1}{2}+\frac{1}{2}a)} \end{aligned} \quad (30)$$

$${}_2F_1(1, -a; a; -1) = \frac{\sqrt{\pi}}{2} \frac{\Gamma(a)}{\Gamma(a+\frac{1}{2})} + 1 \quad (31)$$

$${}_2F_1(a, b; c; \frac{1}{2}) = 2^a {}_2F_1(a, c-b; c; -1) \quad (32)$$

$${}_2F_1(a, b; \frac{1}{2}(a+b+1); \frac{1}{2}) = \frac{\Gamma(\frac{1}{2})\Gamma[\frac{1}{2}(1+a+b)]}{\Gamma[\frac{1}{2}(1+a)]\Gamma[\frac{1}{2}(1+b)]} \quad (33)$$

$${}_2F_1(a, 1-a; c; \frac{1}{2}) = \frac{\Gamma(\frac{1}{2}c)\Gamma[\frac{1}{2}(c+1)]}{\Gamma[\frac{1}{2}(a+c)]\Gamma[\frac{1}{2}(1+c-a)]} \quad (34)$$

$${}_2F_1(a, b; c; 1) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}. \quad (35)$$

KUMMER'S FIRST FORMULA gives

$$\begin{aligned} & {}_2F_1(\frac{1}{2}+m-k, -n; 2m+1; 1) \\ &= \frac{\Gamma(2m+1)\Gamma(m+\frac{1}{2}+k+n)}{\Gamma(m+\frac{1}{2}+k)\Gamma(2m+1+n)}, \end{aligned} \quad (36)$$

where  $m \neq -1/2, -1, -3/2, \dots$ . Many additional identities are given by Abramowitz and Stegun (1972, p. 557).

Hypergeometric functions can be generalized to GENERALIZED HYPERGEOMETRIC FUNCTIONS

$${}_nF_m(a_1, \dots, a_n; b_1, \dots, b_m; z). \quad (37)$$

A function of the form  ${}_1F_1(a; b; z)$  is called a CONFLUENT HYPERGEOMETRIC FUNCTION, and a function of the form  ${}_0F_1(; b; z)$  is called a CONFLUENT HYPERGEOMETRIC LIMIT FUNCTION.

#### Hypergeometric Identity

A relation expressing a sum potentially involving BINOMIAL COEFFICIENTS, FACTORIALS, RATIONAL FUNCTIONS, and power functions in terms of a simple result. Thanks to results by Fasenmyer, Gosper, Zeilberger, Wilf, and Petkovšek, the problem of determining whether a given hypergeometric sum is expressible in simple closed form and, if so, finding the form, is now (subject to a mild restriction) completely solved. The algorithm which does so has been implemented in several computer algebra packages and is called ZEILBERGER'S ALGORITHM.

#### Hypergeometric Polynomial

see JACOBI POLYNOMIAL

#### Hypergeometric Series

A hypergeometric series  $\sum_k a_k$  is a series for which  $a_0 = 1$  and the ratio of consecutive terms is a RATIONAL FUNCTION of the summation index  $k$ , i.e., one for which

$$\frac{a_{k+1}}{a_k} = \frac{P(k)}{Q(k)},$$

with  $P(k)$  and  $Q(k)$  POLYNOMIALS. The functions generated by hypergeometric series are called HYPERGEOMETRIC FUNCTIONS or, more generally, GENERALIZED HYPERGEOMETRIC FUNCTIONS. If the polynomials are completely factored, the ratio of successive terms can be written

$$\frac{a_{k+1}}{a_k} = \frac{P(k)}{Q(k)} = \frac{(k+a_1)(k+a_2)\cdots(k+a_p)}{(k+b_1)(k+b_2)\cdots(k+b_q)(k+1)},$$

where the factor of  $k+1$  in the DENOMINATOR is present for historical reasons of notation, and the resulting GENERALIZED HYPERGEOMETRIC FUNCTION is written

$${}_pF_q \left[ \begin{matrix} a_1 & a_2 & \cdots & a_p \\ b_1 & b_2 & \cdots & b_q \end{matrix} ; x \right] = \sum_{k=0}^{\infty} a_k x^k.$$

If  $p = 2$  and  $q = 1$ , the function becomes a traditional HYPERGEOMETRIC FUNCTION  ${}_2F_1(a, b; c; x)$ .

Many sums can be written as GENERALIZED HYPERGEOMETRIC FUNCTIONS by inspections of the ratios of consecutive terms in the generating hypergeometric series.

### Hyperparallel

Two lines in HYPERBOLIC GEOMETRY which diverge from each other in both directions.

see also ANTIPARALLEL, IDEAL POINT, PARALLEL

### Hyperperfect Number

A number  $n$  is called  $k$ -hyperperfect if

$$n = 1 + k \sum_i d_i,$$

where the summation is over the PROPER DIVISORS with  $1 < d_i < n$ , giving

$$k\sigma(n) = (k+1)n + k + 1,$$

where  $\sigma(n)$  is the DIVISOR FUNCTION. The first few hyperperfect numbers are 21, 301, 325, 697, 1333, ... (Sloane's A007592). 2-hyperperfect numbers include 21, 2133, 19521, 176661, ... (Sloane's A007593), and the first 3-hyperperfect number is 325.

### Hyperplane

Let  $a_1, a_2, \dots, a_n$  be SCALARS not all equal to 0. Then the SET  $S$  consisting of all VECTORS

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix}$$

in  $\mathbb{R}^n$  such that

$$a_1x_1 + a_2x_2 + \dots + a_nx_n = 0$$

is a SUBSPACE of  $\mathbb{R}^n$  called a hyperplane. More generally, a hyperplane is any co-dimension 1 vector SUBSPACE of a VECTOR SPACE. Equivalently, a hyperplane  $V$  in a VECTOR SPACE  $W$  is any SUBSPACE such that  $W/V$  is 1-dimensional. Equivalently, a hyperplane is the KERNEL of any NONZERO linear MAP from the VECTOR SPACE to the underlying FIELD.

### Hyperreal Number

Hyperreal numbers are an extension of the REAL NUMBERS to include certain classes of infinite and infinitesimal numbers. A hyperreal number is said to be finite IFF  $|x| < n$  for some INTEGER  $n$ .  $x$  is said to be infinitesimal IFF  $|x| < 1/n$  for all INTEGERS  $n$ .

### Hyperspace

A SPACE having DIMENSION  $n > 3$ .

### Hypersphere

The  $n$ -hypersphere (often simply called the  $n$ -sphere) is a generalization of the CIRCLE ( $n = 2$ ) and SPHERE ( $n = 3$ ) to dimensions  $n \geq 4$ . It is therefore defined as the set of  $n$ -tuples of points  $(x_1, x_2, \dots, x_n)$  such that

$$x_1^2 + x_2^2 + \dots + x_n^2 = R^2, \quad (1)$$

where  $R$  is the RADIUS of the hypersphere. The CONTENT (i.e.,  $n$ -D VOLUME) of an  $n$ -hypersphere of RADIUS  $R$  is given by

$$V_n = \int_0^R S_n r^{n-1} dr = \frac{S_n R^n}{n}, \quad (2)$$

where  $S_n$  is the hyper-SURFACE AREA of an  $n$ -sphere of unit radius. But, for a unit hypersphere, it must be true that

$$\begin{aligned} S_n \int_0^\infty e^{-r^2} r^{n-1} dr \\ = \underbrace{\int_{-\infty}^\infty \dots \int_{-\infty}^\infty}_{n} e^{-(x_1^2 + \dots + x_n^2)} dx_1 \dots dx_n \\ = \left( \int_{-\infty}^\infty e^{-x^2} dx \right)^n. \end{aligned} \quad (3)$$

But the GAMMA FUNCTION can be defined by

$$\Gamma(m) = 2 \int_0^\infty e^{-r^2} r^{2m-1} dr, \quad (4)$$

so

$$\frac{1}{2} S_n \Gamma(\frac{1}{2}n) = [\Gamma(\frac{1}{2})]^n = (\pi^{1/2})^n \quad (5)$$

$$S_n = \frac{2\pi^{n/2}}{\Gamma(\frac{1}{2}n)}. \quad (6)$$

This gives the RECURRENCE RELATION

$$S_{n+2} = \frac{2\pi S_n}{n}. \quad (7)$$

Using  $\Gamma(n+1) = n\Gamma(n)$  then gives

$$V_n = \frac{S_n R^n}{n} = \frac{\pi^{n/2} R^n}{(\frac{1}{2}n)\Gamma(\frac{1}{2}n)} = \frac{\pi^{n/2} R^n}{\Gamma(1 + \frac{1}{2}n)} \quad (8)$$

(Conway and Sloane 1993).

Strangely enough, the hyper-SURFACE AREA and CONTENT reach MAXIMA and then decrease towards 0 as  $n$  increases. The point of MAXIMAL hyper-SURFACE AREA satisfies

$$\frac{dS_n}{dn} = \frac{\pi^{n/2} [\ln \pi - \psi_0(\frac{1}{2}n)]}{\Gamma(\frac{1}{2}n)} = 0, \quad (9)$$

where  $\psi_0(x) \equiv \Psi(x)$  is the DIGAMMA FUNCTION. The point of MAXIMAL CONTENT satisfies

$$\frac{dV_n}{dn} = \frac{\pi^{n/2} [\ln \pi - \psi_0(1 + \frac{1}{2}n)]}{2\Gamma(1 + \frac{1}{2}n)} = 0. \quad (10)$$

Neither can be solved analytically for  $n$ , but the numerical solutions are  $n = 7.25695\dots$  for hyper-SURFACE AREA and  $n = 5.25695\dots$  for CONTENT. As a result, the 7-D and 5-D hyperspheres have MAXIMAL hyper-SURFACE AREA and CONTENT, respectively (Le Lionnais 1983).

$n$	$V_n$	$V_n/V_{n-\text{cube}}$	$S_n$
0	1	1	0
1	2	1	2
2	$\pi$	$\frac{1}{4}\pi$	$2\pi$
3	$\frac{4}{3}\pi$	$\frac{1}{6}\pi$	$4\pi$
4	$\frac{1}{2}\pi^2$	$\frac{1}{32}\pi^2$	$2\pi^2$
5	$\frac{8}{15}\pi^2$	$\frac{1}{60}\pi^2$	$\frac{8}{3}\pi^2$
6	$\frac{1}{6}\pi^3$	$\frac{1}{384}\pi^3$	$\pi^3$
7	$\frac{16}{105}\pi^3$	$\frac{1}{840}\pi^3$	$\frac{16}{15}\pi^3$
8	$\frac{1}{24}\pi^4$	$\frac{1}{6144}\pi^4$	$\frac{1}{3}\pi^4$
9	$\frac{32}{945}\pi^4$	$\frac{1}{15120}\pi^4$	$\frac{32}{105}\pi^4$
10	$\frac{1}{120}\pi^5$	$\frac{1}{122880}\pi^5$	$\frac{1}{12}\pi^5$

In 4-D, the generalization of SPHERICAL COORDINATES is defined by

$$x_1 = R \sin \psi \sin \phi \cos \theta \quad (11)$$

$$x_2 = R \sin \psi \sin \phi \sin \theta \quad (12)$$

$$x_3 = R \sin \psi \cos \phi \quad (13)$$

$$x_4 = R \cos \psi. \quad (14)$$

The equation for a 4-sphere is

$$x_1^2 + x_2^2 + x_3^2 + x_4^2 = R^2, \quad (15)$$

and the LINE ELEMENT is

$$ds^2 = R^2 [d\psi^2 + \sin^2 \psi (d\phi^2 + \sin^2 \phi d\theta^2)]. \quad (16)$$

By defining  $r \equiv R \sin \psi$ , the LINE ELEMENT can be rewritten

$$ds^2 = \frac{dr^2}{(1 - \frac{r^2}{R^2})} + r^2 (d\phi^2 + \sin^2 \phi d\theta^2). \quad (17)$$

The hyper-SURFACE AREA is therefore given by

$$\begin{aligned} S_4 &= \int_0^\pi R d\psi \int_0^\pi R \sin \psi d\phi \int_0^{2\pi} R \sin \psi \sin \phi d\theta \\ &= 2\pi^2 R^3. \end{aligned} \quad (18)$$

## Hypersphere Packing

Draw unit  $n$ -spheres in an  $n$ -D space centered at all  $\pm 1$  coordinates. Then place an additional HYPERSPHERE at the origin tangent to the other HYPERSPHERES. Then the central HYPERSPHERE is contained with the HYPERSPHERE with VERTICES at the center of the other spheres for  $n$  between 2 and 8. However, for  $n = 9$ , the central HYPERSPHERE just touches the bounding HYPERSPHERE, and for  $n > 9$ , the HYPERSPHERE is partially outside the hypercube. This can be seen by finding the distance from the origin to the center of one of the HYPERSPHERES

$$\underbrace{\sqrt{(\pm 1)^2 + \dots + (\pm 1)^2}}_n = \sqrt{n}.$$

The radius of the central sphere is therefore  $\sqrt{n} - 1$ . The distance from the origin to the center of the bounding hypercube is always 2 (two radii), so the center HYPERSPHERE is tangent when  $\sqrt{n} - 1 = 2$ , or  $n = 9$ , and outside for  $n > 9$ .

The analog of face-centered cubic packing is the densest lattice in 4- and 5-D. In 8-D, the densest lattice packing is made up of two copies of face-centered cubic. In 6- and 7-D, the densest lattice packings are cross-sections of the 8-D case. In 24-D, the densest packing appears to be the LEECH LATTICE. For high dimensions ( $\sim 1000$ -D), the densest known packings are nonlattice. The densest lattice packings in  $n$ -D have been rigorously proved to have PACKING DENSITY 1,  $\pi/(2\sqrt{3})$ ,  $\pi/(3\sqrt{2})$ ,  $\pi^2/16$ ,  $\pi^2/(15\sqrt{2})$ ,  $\pi^3/(48\sqrt{3})$ ,  $\pi^3/105$ , and  $\pi^4/384$  (Finch).

The largest number of unit CIRCLES which can touch another is six. For SPHERES, the maximum number is 12. Newton considered this question long before a proof was published in 1874. The maximum number of hyperspheres that can touch another in  $n$ -D is the so-called KISSING NUMBER.

## Hypervolume

see CONTENT

## Hypocycloid

The curve produced by a small CIRCLE of RADIUS  $b$  rolling around the inside of a large CIRCLE of RADIUS  $a > b$ . A hypocycloid is a HYPOTROCHOID with  $h = b$ . To derive the equations of the hypocycloid, call the ANGLE by which a point on the small CIRCLE rotates about its center  $\vartheta$ , and the ANGLE from the center of the large CIRCLE to that of the small CIRCLE  $\phi$ . Then

$$(a - b)\phi = b\vartheta, \quad (1)$$

so

$$\vartheta = \frac{a - b}{b}\phi. \quad (2)$$

Call  $\rho \equiv a - 2b$ . If  $x(0) = \rho$ , then the first point is at minimum radius, and the Cartesian parametric equations of the hypocycloid are

$$\begin{aligned} x &= (a - b) \cos \phi - b \cos \vartheta \\ &= (a - b) \cos \phi - b \cos \left( \frac{a - b}{b} \phi \right) \end{aligned} \quad (3)$$

$$\begin{aligned} y &= (a - b) \sin \phi + b \sin \vartheta \\ &= (a - b) \sin \phi + b \sin \left( \frac{a - b}{b} \phi \right). \end{aligned} \quad (4)$$

If  $x(0) = a$  instead so the first point is at maximum radius (on the CIRCLE), then the equations of the hypocycloid are

$$x = (a - b) \cos \phi + b \cos \left( \frac{a - b}{b} \phi \right) \quad (5)$$

$$y = (a - b) \sin \phi - b \sin \left( \frac{a - b}{b} \phi \right). \quad (6)$$

An  $n$ -cusped non-self-intersecting hypocycloid has  $a/b = n$ . A 2-cusped hypocycloid is a LINE SEGMENT, as can be seen by setting  $a = b$  in equations (3) and (4) and noting that the equations simplify to

$$x = a \sin \phi \quad (7)$$

$$y = 0. \quad (8)$$

A 3-cusped hypocycloid is called a DELTOID or TRICUSPOID, and a 4-cusped hypocycloid is called an ASTROID. If  $a/b$  is rational, the curve closes on itself and has  $b$  cusps. If  $a/b$  is IRRATIONAL, the curve never closes and fills the entire interior of the CIRCLE.

$n$ -hypocycloids can also be constructed by beginning with the DIAMETER of a CIRCLE, offsetting one end by a series of steps while at the same time offsetting the other end by steps  $n$  times as large in the opposite direction and extending beyond the edge of the CIRCLE. After traveling around the CIRCLE once, an  $n$ -cusped hypocycloid is produced, as illustrated above (Madachy 1979).

Let  $r$  be the radial distance from a fixed point. For RADIUS OF TORSION  $\rho$  and ARC LENGTH  $s$ , a hypocycloid can given by the equation

$$s^2 + \rho^2 = 16r^2 \quad (9)$$

(Kreyszig 1991, pp. 63–64). A hypocycloid also satisfies

$$\sin^2 \psi = \frac{\rho^2}{a^2 - \rho^2} \frac{a^2 - r^2}{r^2}, \quad (10)$$

where

$$r \frac{dr}{d\theta} = \tan \psi \quad (11)$$

and  $\psi$  is the ANGLE between the RADIUS VECTOR and the TANGENT to the curve.

The ARC LENGTH of the hypocycloid can be computed as follows

$$\begin{aligned} x' &= -(a-b) \sin \phi - (a-b) \sin \left( \frac{a-b}{b} \phi \right) \\ &= (a-b) \left[ \sin \phi + \sin \left( \frac{a-b}{b} \phi \right) \right] \end{aligned} \quad (12)$$

$$\begin{aligned} y' &= (a-b) \cos \phi - (a-b) \cos \left( \frac{a-b}{b} \phi \right) \\ &= (a-b) \left[ \cos \phi - \cos \left( \frac{a-b}{b} \phi \right) \right] \end{aligned} \quad (13)$$

$$\begin{aligned} x'^2 + y'^2 &= (a-b)^2 \left[ \sin^2 \phi + 2 \sin \phi \sin \left( \frac{a-b}{b} \phi \right) \right. \\ &\quad \left. + \sin^2 \left( \frac{a-b}{b} \phi \right) + \cos^2 \phi - 2 \cos \phi \cos \left( \frac{a-b}{b} \phi \right) \right. \\ &\quad \left. + \cos^2 \left( \frac{a-b}{b} \phi \right) \right] \\ &= (a-b)^2 \left\{ 2 + 2 \left[ \sin \phi \sin \left( \frac{a-b}{b} \phi \right) \right. \right. \\ &\quad \left. \left. - \cos \phi \cos \left( \frac{a-b}{b} \phi \right) \right] \right\} \\ &= 2(a-b)^2 \left[ 1 - \cos \left( \phi + \frac{a-b}{b} \phi \right) \right] \\ &= 4(a-b)^2 \frac{1}{2} \left[ 1 - \cos \left( \frac{a}{b} \phi \right) \right] = 4(a-b)^2 \sin^2 \left( \frac{a\phi}{2b} \right), \end{aligned} \quad (14)$$

so

$$ds = \sqrt{x'^2 + y'^2} d\phi = 2(a-b) \sin \left( \frac{a\phi}{2b} \right) d\phi \quad (15)$$

for  $\phi \leq (b/2a)\pi$ . Integrating,

$$\begin{aligned} s(\phi) &= \int_0^\phi ds = 2(a-b) \left[ -\frac{2b}{a} \cos \left( \frac{a\phi}{2b} \right) \right]_0^\phi \\ &= \frac{4b(a-b)}{a} \left[ -\cos \left( \frac{a}{2b} \phi \right) + 1 \right] \\ &= \frac{8b(a-b)}{a} \sin^2 \left( \frac{a\phi}{4b} \right). \end{aligned} \quad (16)$$

The length of a single cusp is then

$$s \left( 2\pi \frac{b}{a} \right) = \frac{8b(a-b)}{a} \sin^2 \left( \frac{\pi}{2} \right) = \frac{8b(a-b)}{a}. \quad (17)$$

If  $n \equiv a/b$  is rational, then the curve closes on itself without intersecting after  $n$  cusps. For  $n \equiv a/b$  and with  $x(0) = a$ , the equations of the hypocycloid become

$$x = \frac{1}{n} [(n-1) \cos \phi - \cos[(n-1)\phi]]a, \quad (18)$$

$$y = \frac{1}{n} [(n-1) \sin \phi + \sin[(n-1)\phi]]a, \quad (19)$$

and

$$s_n = n \frac{8b(bn-b)}{nb} = 8b(n-1) = \frac{8a(n-1)}{n}. \quad (20)$$

Compute

$$\begin{aligned} xy' - yx' &= \left[ (a-b) \cos \phi + b \cos \left( \frac{a-b}{b} \phi \right) \right] (b-a) \\ &\quad \times \left[ \sin \phi + \sin \left( \frac{a-b}{b} \phi \right) \right] \\ &\quad - \left[ (a-b) \sin \phi - b \sin \left( \frac{a-b}{b} \phi \right) \right] (a-b) \\ &\quad \times \left[ \cos \phi - \cos \left( \frac{a-b}{b} \phi \right) \right] \\ &= 2(a^2 - 3ab + 2b^2) \sin^2 \left( \frac{a\phi}{2b} \right). \end{aligned} \quad (21)$$

The AREA of one cusp is then

$$\begin{aligned}
 A &= \frac{1}{2} \int_0^{2\pi b/a} (xy' - yx') d\phi \\
 &= (a^2 - 3ab + 2b^2) \left[ \frac{at - b \sin\left(\frac{at}{b}\right)}{2a} \right]_a^{2\pi b/a} \\
 &= (a^2 - 3ab + 2b^2) \left[ \frac{a \left(2\pi \frac{b}{a}\right)}{2a} \right] \\
 &= \frac{b(a^2 - 3ab + 2b^2)}{a} \pi. \quad (22)
 \end{aligned}$$

If  $n = a/b$  is rational, then after  $n$  cusps,

$$\begin{aligned}
 A_n &= n\pi \frac{b(a^2 - 3ab + 2b^2)}{a} = n\pi \frac{\frac{a}{n} \left(a^2 - 3a\frac{a}{n} + 2\frac{a^2}{n^2}\right)}{a} \\
 &= \frac{n^2 - 3n + 2}{n^2} \pi a^2 = \frac{(n-1)(n-2)}{n^2} \pi a^2. \quad (23)
 \end{aligned}$$

The equation of the hypocycloid can be put in a form which is useful in the solution of CALCULUS OF VARIATIONS problems with radial symmetry. Consider the case  $x(0) = \rho$ , then

$$\begin{aligned}
 r^2 &= x^2 + y^2 \\
 &= \left[ (a-b)^2 \cos^2 \phi - 2(a-b)b \cos \phi \cos\left(\frac{a-b}{b}\phi\right) \right. \\
 &\quad \left. + b^2 \cos^2\left(\frac{a-b}{b}\phi\right) \right. \\
 &\quad \left. + (a-b)^2 \sin^2 \phi + 2(a-b)b \sin \phi \sin\left(\frac{a-b}{b}\phi\right) \right. \\
 &\quad \left. + b^2 \sin^2\left(\frac{a-b}{b}\phi\right) \right] \\
 &= \left\{ (a-b)^2 + b^2 - 2(a-b)b \right. \\
 &\quad \left. \times \left[ \cos \phi \cos\left(\frac{a-b}{b}\phi\right) - \sin \phi \sin\left(\frac{a-b}{b}\phi\right) \right] \right\} \\
 &= (a-b)^2 + b^2 - 2(a-b)b \cos\left(\frac{a}{b}\phi\right). \quad (24)
 \end{aligned}$$

But  $\rho = a - 2b$ , so  $b = (a - \rho)/2$ , which gives

$$\begin{aligned}
 (a-b)^2 + b^2 &= \left[a - \frac{1}{2}(a-\rho)\right]^2 + \left[\frac{1}{2}(a-\rho)\right]^2 \\
 &= \left[\frac{1}{2}(a+\rho)\right]^2 + \left[\frac{1}{2}(a-\rho)\right]^2 \\
 &= \frac{1}{4}(a^2 + 2a\rho + \rho^2 + a^2 - 2a\rho + \rho^2) \\
 &= \frac{1}{2}(a^2 + \rho^2) \quad (25)
 \end{aligned}$$

$$\begin{aligned}
 2(a-b)b &= 2\left[a - \frac{1}{2}(a-\rho)\right]\frac{1}{2}(a-\rho) \\
 &= \frac{1}{2}(a+\rho)(a-\rho) = \frac{1}{2}(a^2 - \rho^2). \quad (26)
 \end{aligned}$$

Now let

$$2\Omega t \equiv \frac{a}{b}\phi, \quad (27)$$

so

$$\phi = \frac{a-\rho}{a}\Omega t \quad (28)$$

then

$$\begin{aligned}
 r^2 &= \frac{1}{2}(a^2 + \rho^2) - \frac{1}{2}(a^2 - \rho^2) \cos\left(\frac{a}{b}\phi\right) \\
 &= \frac{1}{2}(a^2 + \rho^2) - \frac{1}{2}(a^2 - \rho^2) \cos(2\Omega t). \quad (30)
 \end{aligned}$$

The POLAR ANGLE is

$$\tan \theta \equiv \frac{y}{x} = \frac{(a-b) \sin \phi + b \sin\left(\frac{a-b}{a}\phi\right)}{(a-b) \cos \phi - b \cos\left(\frac{a-b}{a}\phi\right)}. \quad (31)$$

But

$$b = \frac{1}{2}(a - \rho) \quad (32)$$

$$a - b = \frac{1}{2}(a + \rho) \quad (33)$$

$$\frac{a-b}{b} = \frac{a+\rho}{a-\rho}, \quad (34)$$

so

$$\begin{aligned}
 \tan \theta &= \frac{\frac{1}{2}(a+\rho) \sin \phi + \frac{1}{2}(a-\rho) \sin\left(\frac{a+\rho}{a-\rho}\phi\right)}{\frac{1}{2}(a+\rho) \cos \phi - \frac{1}{2}(a-\rho) \cos\left(\frac{a+\rho}{a-\rho}\phi\right)} \\
 &= \frac{(a+\rho) \sin\left(\frac{a-\rho}{a}\Omega t\right) + (a-\rho) \sin\left(\frac{a+\rho}{a}\Omega t\right)}{(a+\rho) \cos\left(\frac{a-\rho}{a}\Omega t\right) - (a-\rho) \cos\left(\frac{a+\rho}{a}\Omega t\right)} \\
 &= \frac{a \left[ \sin\left(\frac{a-\rho}{a}\Omega t\right) + \sin\left(\frac{a+\rho}{a}\Omega t\right) \right] + \rho \left[ \sin\left(\frac{a-\rho}{a}\Omega t\right) - \sin\left(\frac{a+\rho}{a}\Omega t\right) \right]}{a \left[ \cos\left(\frac{a-\rho}{a}\Omega t\right) - \cos\left(\frac{a+\rho}{a}\Omega t\right) \right] + \rho \left[ \cos\left(\frac{a-\rho}{a}\Omega t\right) + \cos\left(\frac{a+\rho}{a}\Omega t\right) \right]} \\
 &= \frac{2a \sin(\Omega t) \cos\left(\frac{\rho}{a}\Omega t\right) - 2\rho \cos(\Omega t) \sin\left(\frac{\rho}{a}\Omega t\right)}{2a \sin(\Omega t) \sin\left(\frac{\rho}{a}\Omega t\right) + 2\rho \cos(\Omega t) \cos\left(\frac{\rho}{a}\Omega t\right)} \\
 &= \frac{a \tan(\Omega t) - \rho \tan\left(\frac{\rho}{a}\Omega t\right)}{a \tan(\Omega t) \tan\left(\frac{\rho}{a}\Omega t\right) + \rho}. \quad (35)
 \end{aligned}$$

Computing

$$\begin{aligned}
 \tan\left(\theta + \frac{\rho}{a}\Omega t\right) &= \frac{\left[a \tan(\Omega t) - \rho \tan\left(\frac{\rho}{a}\Omega t\right) + \tan\left(\frac{\rho}{a}\Omega t\right)\right] \times \left[a \tan(\Omega t) \tan\left(\frac{\rho}{a}\Omega t\right) + \rho\right]}{\left[a \tan(\Omega t) \tan\left(\frac{\rho}{a}\Omega t\right) + \rho\right] - \left[a \tan(\Omega t) - \rho \tan\left(\frac{\rho}{a}\Omega t\right)\right] \tan\left(\frac{\rho}{a}\Omega t\right)} \\
 &= \frac{a \tan(\Omega t) \left[1 + \tan^2\left(\frac{\rho}{a}\Omega t\right)\right]}{\rho \left[1 + \tan^2\left(\frac{\rho}{a}\Omega t\right)\right]} \\
 &= \frac{a}{\rho} \tan(\Omega t), \quad (36)
 \end{aligned}$$

then gives

$$\theta = \tan^{-1} \left[ \frac{a}{\rho} \tan(\Omega t) \right] - \frac{\rho}{a}\Omega t. \quad (37)$$

Finally, plugging back in gives

$$\begin{aligned}\theta &= \tan^{-1} \left[ \frac{a}{\rho} \tan \left( \frac{a}{a-\rho} \phi \right) \right] - \frac{\rho}{a} \frac{a}{a-\rho} \phi \\ &= \tan^{-1} \left[ \frac{a}{\rho} \tan \left( \frac{a}{a-\rho} \phi \right) \right] - \frac{\rho}{a-\rho} \phi. \quad (38)\end{aligned}$$

This form is useful in the solution of the SPHERE WITH TUNNEL problem, which is the generalization of the BRACHISTOCURVE PROBLEM, to find the shape of a tunnel drilled through a SPHERE (with gravity varying according to Gauss's law for gravitation) such that the travel time between two points on the surface of the SPHERE under the force of gravity is minimized.

#### Hypocycloid Evolute

For  $x(0) = a$ ,

$$\begin{aligned}x &= \frac{a}{a-2b} \left[ (a-b) \cos \phi - b \cos \left( \frac{a-b}{b} \phi \right) \right] \\ y &= \frac{a}{a-2b} \left[ (a-b) \sin \phi + b \sin \left( \frac{a-b}{b} \phi \right) \right].\end{aligned}$$

If  $a/b = n$ , then

$$\begin{aligned}x &= \frac{1}{n-2} [(n-1) \cos \phi - \cos[(n-1)\phi]a \\ y &= \frac{1}{n-2} [(n-1) \sin \phi + \sin[(n-1)\phi]a.\end{aligned}$$

This is just the original HYPOCYCLOID scaled by the factor  $(n-2)/n$  and rotated by  $1/(2n)$  of a turn.

#### Hypocycloid Involute

The HYPOCYCLOID

$$\begin{aligned}x &= \frac{a}{a-2b} \left[ (a-b) \cos \phi - b \cos \left( \frac{a-b}{b} \phi \right) \right] \\ y &= \frac{a}{a-2b} \left[ (a-b) \sin \phi + b \sin \left( \frac{a-b}{b} \phi \right) \right]\end{aligned}$$

has INVOLUTE

$$\begin{aligned}x &= \frac{a-2b}{a} \left[ (a-b) \cos \phi + b \cos \left( \frac{a-b}{b} \phi \right) \right] \\ y &= \frac{a-2b}{a} \left[ (a-b) \sin \phi - b \sin \left( \frac{a-b}{b} \phi \right) \right],\end{aligned}$$

which is another HYPOCYCLOID.

#### Hypocycloid Pedal Curve

The PEDAL CURVE for a PEDAL POINT at the center is a ROSE.

**Hypoellipse**

$$y^{n/m} + c \left| \frac{x}{a} \right|^{n/m} - c = 0,$$

with  $n/m < 2$ . If  $n/m > 2$ , the curve is a HYPERELLIPSE.

# I

i

The IMAGINARY NUMBER  $i$  is defined as  $i \equiv \sqrt{-1}$ . However, for some reason engineers and physicists prefer the symbol  $j$  to  $i$ . Numbers of the form  $z = x + iy$  where  $x$  and  $y$  are REAL NUMBERS are called COMPLEX NUMBERS, and when  $z$  is used to denote a COMPLEX NUMBER, it is sometimes (in older texts) called an "AFFIX."

The SQUARE ROOT of  $i$  is

$$\sqrt{i} = \pm \frac{i+1}{\sqrt{2}}, \quad (1)$$

since

$$\left[ \frac{1}{\sqrt{2}}(i+1) \right]^2 = \frac{1}{2}(i^2 + 2i + 1) = i. \quad (2)$$

This can be immediately derived from the EULER FORMULA with  $x = \pi/2$ ,

$$i = e^{i\pi/2} \quad (3)$$

$$\sqrt{i} = \sqrt{e^{i\pi/2}} = e^{i\pi/4} = \cos\left(\frac{1}{4}\pi\right) + i\sin\left(\frac{1}{4}\pi\right) = \frac{1+i}{\sqrt{2}}. \quad (4)$$

The PRINCIPAL VALUE of  $i^i$  is

$$i^i = (e^{i\pi/2})^i = e^{i^2\pi/2} = e^{-\pi/2} = 0.207879\dots \quad (5)$$

## Icosahedral Equation

Hunt (1996) gives the "dehomogenized" icosahedral equation as

$$[(z^{20} + 1) - 228(z^{15} - z^5) + 494z^{10}]^3 + 1728uz^5(z^{10} + 11z^5 - 1)^5 = 0.$$

Other forms include

$$I(u, v, Z) = u^5 v^5 (u^{10} + 11u^5 v^5 - v^{10})^5 \\ - [u^{30} + v^{30} - 10005(u^{20} v^{10} + u^{10} v^{20}) \\ + 522(u^2 5v^5 - u^5 v^2 5)]^2 Z = 0$$

and

$$I(z, 1, Z) = z^5 (-1 + 11z^5 + z^{10})^5 \\ - [1 + z^{30} - 10005(z^{10} + z^{20}) + 522(-z^5 + z^{25})]^2 Z = 0.$$

### Icosahedron

A PLATONIC SOLID ( $P_5$ ) with 12 VERTICES, 30 EDGES, and 20 equivalent EQUILATERAL TRIANGLE faces  $20\{3\}$ . It is described by the SCHLÄFLI SYMBOL  $\{3,5\}$ . It is also UNIFORM POLYHEDRON  $U_{22}$  and has WYTHOFF SYMBOL  $5|23$ . The icosahedron has the ICOSAHDREDAL GROUP  $I_h$  of symmetries.

A plane PERPENDICULAR to a  $C_5$  axis of an icosahedron cuts the solid in a regular DECAGONAL CROSS-SECTION (Holden 1991, pp. 24-25).

A construction for an icosahedron with side length  $a = \sqrt{50 - 10\sqrt{5}}/5$  places the end vertices at  $(0, 0, \pm 1)$  and the central vertices around two staggered CIRCLES of RADII  $\frac{2}{5}\sqrt{5}$  and heights  $\pm \frac{1}{5}\sqrt{5}$ , giving coordinates

$$\pm \left( \frac{2}{5}\sqrt{5} \cos\left(\frac{2}{5}i\pi\right), \frac{2}{5}\sqrt{5} \sin\left(\frac{2}{5}i\pi\right), \frac{1}{5}\sqrt{5} \right) \quad (1)$$

for  $i = 0, 1, \dots, 4$ , where all the plus signs or minus signs are taken together. Explicitly, these coordinates are

$$x_0^\pm = \pm \left( \frac{2}{5}\sqrt{5}, 0, \frac{1}{5}\sqrt{5} \right) \quad (2)$$

$$x_1^\pm = \pm \left( \frac{1}{10}(5 - \sqrt{5}), \frac{1}{10}\sqrt{50 + 10\sqrt{5}}, \frac{1}{5}\sqrt{5} \right) \quad (3)$$

$$x_2^\pm = \pm \left( -\frac{1}{10}(\sqrt{5} + 5), \frac{1}{10}\sqrt{50 - 10\sqrt{5}}, \frac{1}{5}\sqrt{5} \right) \quad (4)$$

$$x_3^\pm = \pm \left( -\frac{1}{10}(\sqrt{5} - 5), -\frac{1}{10}\sqrt{50 - 10\sqrt{5}}, \frac{1}{5}\sqrt{5} \right) \quad (5)$$

$$x_4^\pm = \pm \left( \frac{1}{10}(5 - \sqrt{5}), -\frac{1}{10}\sqrt{50 + 10\sqrt{5}}, \frac{1}{5}\sqrt{5} \right). \quad (6)$$

By a suitable rotation, the VERTICES of an icosahedron of side length 2 can also be placed at  $(0, \pm\phi, \pm 1)$ ,  $(\pm 1, 0, \pm\phi)$ , and  $(\pm\phi, \pm 1, 0)$ , where  $\phi$  is the GOLDEN RATIO. These points divide the EDGES of an OCTAHDREDON into segments with lengths in the ratio  $\phi : 1$ .

The DUAL POLYHEDRON of the icosahedron is the DODECAHEDRON. There are 59 distinct icosahedra when each TRIANGLE is colored differently (Coxeter 1969).

To derive the VOLUME of an icosahedron having edge length  $a$ , consider the orientation so that two VERTICES are oriented on top and bottom. The vertical distance between the top and bottom PENTAGONAL DIPYRAMIDS is then given by

$$z = \sqrt{\ell^2 - x^2}, \quad (7)$$

where

$$\ell = \frac{1}{2}\sqrt{3}a \quad (8)$$

is the height of an ISOSCELES TRIANGLE, and the SAGITTA  $x \equiv R' - r'$  of the pentagon is

$$x = \frac{1}{2}a\frac{1}{10}\sqrt{25 - 10\sqrt{5}}a, \quad (9)$$

giving

$$x^2 = \frac{1}{20}\sqrt{5 - 2\sqrt{5}}a^2. \quad (10)$$

Plugging (8) and (10) into (7) gives

$$\begin{aligned} z &= a\sqrt{\frac{3}{4} - \frac{1}{20}(5 - 2\sqrt{5})} = a\sqrt{\frac{15 - (5 - 2\sqrt{5})}{20}} \\ &= a\sqrt{\frac{10 + 2\sqrt{5}}{20}} = \frac{1}{2}a\sqrt{\frac{10 + 2\sqrt{5}}{5}} \\ &= \frac{1}{10}\sqrt{50 + 10\sqrt{5}}a, \end{aligned} \quad (11)$$

which is identical to the radius of a PENTAGON of side  $a$ . The CIRCUMRADIUS is then

$$R = h + \frac{1}{2}z, \quad (12)$$

where

$$h = \frac{1}{10}\sqrt{50 - 10\sqrt{5}}a \quad (13)$$

is the height of a PENTAGONAL DIPYRAMID. Therefore,

$$\begin{aligned} R^2 &= (h + \frac{1}{2}z)^2 \\ &= (\frac{1}{10}\sqrt{50 - 10\sqrt{5}} + \frac{1}{20}\sqrt{50 + 10\sqrt{5}})^2 a^2 \\ &= \left(\frac{5}{8} - \frac{3}{8\sqrt{5}} + \frac{\sqrt{20}}{10}\right) a^2 = \frac{1}{8}(5 + \sqrt{5})a. \end{aligned} \quad (14)$$

Taking the square root gives the CIRCUMRADIUS

$$R = \sqrt{\frac{1}{8}(5 + \sqrt{5})}a = \frac{1}{4}\sqrt{10 + 2\sqrt{5}}a \approx 0.95105a. \quad (15)$$

The INRADIUS is

$$r = \frac{1}{12}(3\sqrt{3} + \sqrt{15})a \approx 0.75576a. \quad (16)$$

The square of the INTERRADIUS is

$$\begin{aligned} \rho^2 &= (\frac{1}{2}z)^2 + x_i^2 \\ &= [(\frac{1}{4})(\frac{1}{100})(50 + 10\sqrt{5}) + \frac{1}{100}(25 + 10\sqrt{5})]a^2 \\ &= \frac{1}{8}(3 + \sqrt{5})a^2, \end{aligned} \quad (17)$$

so

$$\rho = \sqrt{\frac{1}{8}(3 + \sqrt{5})}a = \frac{1}{4}(1 + \sqrt{5})a \approx 0.80901a. \quad (18)$$

The AREA of one face is the AREA of an EQUILATERAL TRIANGLE

$$A = \frac{1}{4}a^2\sqrt{3}. \quad (19)$$

The volume can be computed by taking 20 pyramids of height  $r$

$$\begin{aligned} V &= 20[(\frac{1}{3}A)r] = 20\frac{1}{3}\frac{1}{4}\sqrt{3}a^2\frac{1}{12}(3\sqrt{3} + \sqrt{15})a \\ &= \frac{5}{12}(3 + \sqrt{5})a^3. \end{aligned} \quad (20)$$

Apollonius showed that

$$\frac{V_{\text{icosahedron}}}{V_{\text{dodecahedron}}} = \frac{A_{\text{icosahedron}}}{A_{\text{dodecahedron}}}, \quad (21)$$

where  $V$  is the volume and  $A$  the surface area.

#### Icosahedron Stellations

Applying the STELLATION process to the ICOSAHDREDON gives

$$20 + 30 + 60 + 20 + 60 + 120 + 12 + 30 + 60 + 60$$

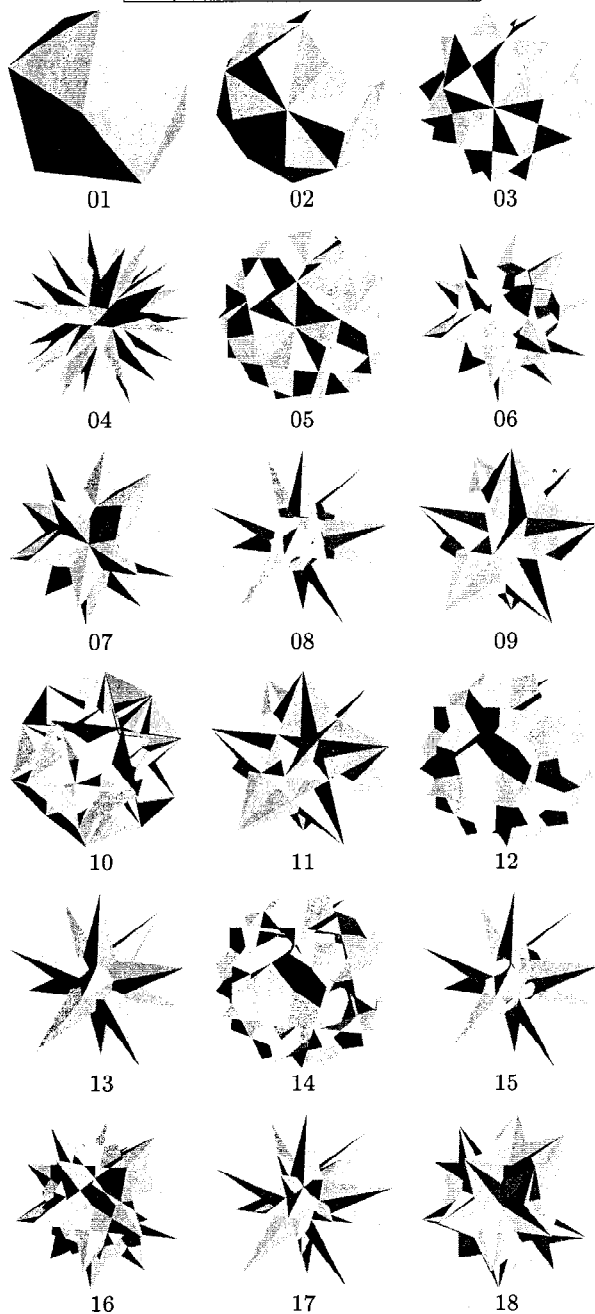

cells of ten different shapes and sizes in addition to the ICOSAHDREDON itself. After application of five restrictions due to J. C. P. Miller to define which forms should be considered distinct, 59 stellations are found to be possible. Miller's restrictions are

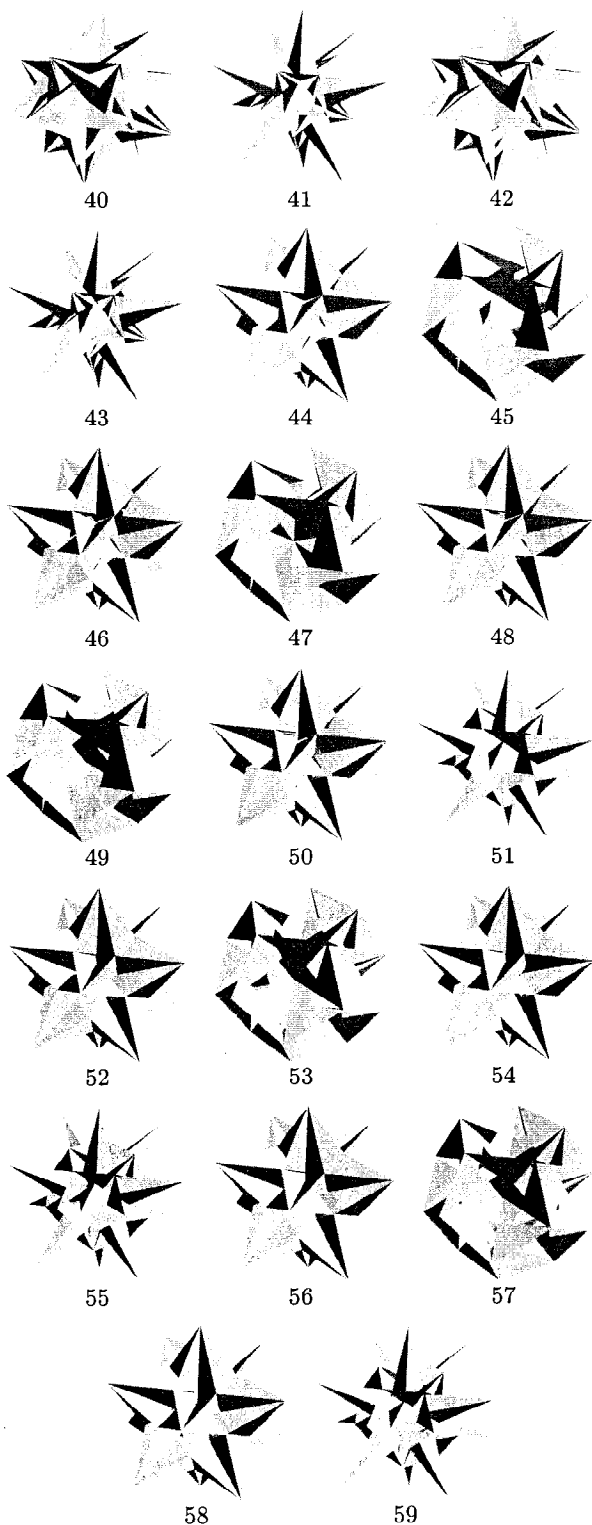

1. The faces must lie in the twenty bounding planes of the icosahedron.
2. The parts of the faces in the twenty planes must be congruent, but those parts lying in one place may be disconnected.
3. The parts lying in one plane must have threefold rotational symmetry with or without reflections.
4. All parts must be accessible, i.e., lie on the outside of the solid.
5. Compounds are excluded that can be divided into two sets, each of which has the full symmetry of the whole.

Of these, 32 have full icosahedral symmetry and 27 are ENANTIOMERIC forms. Four are POLYHEDRON COMPOUNDS, one is a KEPLER-POINSOT SOLID, and one is the DUAL POLYHEDRON of an ARCHIMEDEAN SOLID.

The only STELLATIONS of PLATONIC SOLIDS which are UNIFORM POLYHEDRA are the three DODECAHEDRON STELLATIONS the GREAT ICOSAEDRON (stellation # 11).

#### Icosidodecadodecahedron

The UNIFORM POLYHEDRON  $U_{44}$  whose DUAL POLYHEDRON is the MEDIAL ICOSACRONIC HEXECONTAHEDRON. It has WYTHOFF SYMBOL  $\frac{5}{3}5|3$ . Its faces are  $20\{6\} + 12\{\frac{5}{2}\} + 12\{5\}$ . Its CIRCUMRADIUS for unit edge length is

$$R = \frac{1}{2}\sqrt{7}.$$

#### References

Wenninger, M. J. *Polyhedron Models*. Cambridge, England: Cambridge University Press, pp. 128–129, 1989.

**Icosidodecahedron**

An ARCHIMEDEAN SOLID whose DUAL POLYHEDRON is the RHOMBIC TRIACONTAHEDRON. It is one of the two convex QUASIREGULAR POLYHEDRA and has SCHLÄFLI SYMBOL  $\left\{ \frac{3}{5} \right\}$ . It is also UNIFORM POLYHEDRON  $U_{24}$  and has WYTHOFF SYMBOL  $2 | 3 5$ . Its faces are  $20\{3\} + 12\{5\}$ . The VERTICES of an icosidodecahedron of EDGE length  $2\phi^{-1}$  are  $(\pm 2, 0, 0)$ ,  $(0, \pm 2, 0)$ ,  $(0, 0, \pm 2)$ ,  $(\pm 1, \pm \phi^{-1}, \pm 1)$ ,  $(\pm 1, \pm \phi, \pm \phi^{-1})$ ,  $(\pm \phi^{-1}, \pm 1, \pm \phi)$ . The 30 VERTICES of an OCTAHEDRON 5-COMPOUND form an icosidodecahedron (Ball and Coxeter 1987). FACETED versions include the SMALL ICOSIHEMIDODECAHEDRON and SMALL DODECAHEMIDODECAHEDRON.

The faces of the icosidodecahedron consist of 20 triangles and 12 pentagons. Furthermore, its 60 edges are bisected perpendicularly by those of the reciprocal RHOMBIC TRIACONTAHEDRON (Ball and Coxeter 1987).

The INRADIUS, MIDRADIUS, and CIRCUMRADIUS for unit edge length are

$$\begin{aligned} r &= \frac{1}{8}(5 + 3\sqrt{5}) \approx 1.46353 \\ \rho &= \frac{1}{2}\sqrt{5 + 2\sqrt{5}} \approx 1.53884 \\ R &= \frac{1}{2}(1 + \sqrt{5}) = \phi \approx 1.61803. \end{aligned}$$

**Ideal**

A subset  $I$  of elements in a RING  $R$  which forms an additive GROUP and has the property that, whenever  $x$  belongs to  $R$  and  $y$  belongs to  $I$ , then  $xy$  and  $yx$  belong to  $I$ . For example, the set of EVEN INTEGERS is an ideal in the RING of INTEGERS. Given an ideal  $I$ , it is possible to define a FACTOR RING  $R/I$ .

An ideal may be viewed as a lattice and specified as the finite list of algebraic integers that form a basis for the lattice. Any two bases for the same lattice are equivalent. Ideals have multiplication, and this is basically the Kronecker product of the two bases.

For any ideal  $I$ , there is an ideal  $I_i$  such that

$$II_i = z,$$

where  $z$  is a PRINCIPAL IDEAL, (i.e., an ideal of rank 1). Moreover there is a finite list of ideals  $I_i$  such that this equation may be satisfied for every  $I$ . The size of this list is known as the CLASS NUMBER. In effect, the above relation imposes an EQUIVALENCE RELATION on ideals, and the number of ideals modulo this relation is the class number. When the CLASS NUMBER is 1, the corresponding number RING has unique factorization and, in a sense, the class number is a measure of the failure of unique factorization in the original number ring.

Dedekind (1871) showed that every NONZERO ideal in the domain of INTEGERS of a FIELD is a unique product of PRIME IDEALS.

see also CLASS NUMBER, DIVISOR THEORY, IDEAL NUMBER, MAXIMAL IDEAL, PRIME IDEAL, PRINCIPAL IDEAL

#### References

Malgrange, B. *Ideals of Differentiable Functions*. London: Oxford University Press, 1966.

### Ideal Number

A type of number involving the ROOTS OF UNITY which was developed by Kummer while trying to solve FERMAT'S LAST THEOREM. Although factorization over the INTEGERS is unique (the FUNDAMENTAL THEOREM OF ALGEBRA), factorization is *not* unique over the COMPLEX NUMBERS. Over the ideal numbers, however, factorization in terms of the COMPLEX NUMBERS becomes unique. Ideal numbers were so powerful that they were generalized by Dedekind into the more abstract IDEALS in general RINGS which are a key part of modern abstract ALGEBRA.

see also DIVISOR THEORY, FERMAT'S LAST THEOREM, IDEAL

### Ideal (Partial Order)

An ideal  $I$  of a PARTIAL ORDER  $P$  is a subset of the elements of  $P$  which satisfy the property that if  $y \in I$  and  $x < y$ , then  $x \in I$ . For  $k$  disjoint chains in which the  $i$ th chain contains  $n_i$  elements, there are  $(1 + n_1)(1 + n_2) \cdots (1 + n_k)$  ideals. The number of ideals of a  $n$ -element FENCE POSET is the FIBONACCI NUMBER  $F_n$ .

### Idemfactor

see DYADIC

### Idempotent

An OPERATOR  $\tilde{A}$  such that  $\tilde{A}^2 = \tilde{A}$  or an element of an ALGEBRA  $x$  such that  $x^2 = x$ .

see also AUTOMORPHIC NUMBER, BOOLEAN ALGEBRA, GROUP, SEMIGROUP

### Identity

An identity is a mathematical relationship equating one quantity to another (which may initially appear to be different).

see also ABEL'S IDENTITY, ANDREWS-SCHUR IDENTITY, BAC-CAB IDENTITY, BEAUZAMY AND DÉGOT'S IDENTITY, BELTRAMI IDENTITY, BIANCHI IDENTITIES, BOCHNER IDENTITY, BRAHMAGUPTA IDENTITY, CASSINI'S IDENTITY, CAUCHY-LAGRANGE IDENTITY, CHRISTOFFEL-DARBOUX IDENTITY, CHU-VANDERMONDE IDENTITY, DE MOIVRE'S IDENTITY, DOUGALL-RAMANUJAN IDENTITY, EULER FOUR-SQUARE IDENTITY, EULER IDENTITY, EULER POLYNOMIAL IDENTITY, FERRARI'S IDENTITY, FIBONACCI IDENTITY, FROBENIUS TRIANGLE IDENTITIES, GREEN'S IDENTITIES, HYPERGEOMETRIC IDENTITY, IMAGINARY IDENTITY, JACKSON'S IDENTITY, JACOBI IDENTITIES, JACOBI'S DETERMINANT IDENTITY, LAGRANGE'S IDENTITY, LE CAM'S IDENTITY, LEIBNIZ IDENTITY, LIOUVILLE POLYNOMIAL IDENTITY, MATRIX POLYNOMIAL IDENTITY, MORGADO IDENTITY, NEWTON'S IDENTITIES, QUINTUPLE PRODUCT IDENTITY, RAMANUJAN 6-10-8 IDENTITY, RAMANUJAN COS/COSH IDENTITY, RAMANUJAN'S IDENTITY, RAMANUJAN'S SUM IDENTITY, REZNIK'S IDENTITY, ROGERS-RAMANUJAN IDENTITIES, SCHAAR'S IDENTITY, STREHL IDENTITY, SYLVESTER'S DETERMINANT IDENTITY, TRINOMIAL IDENTITY, VISIBLE POINT VECTOR IDENTITY, WATSON QUINTUPLE PRODUCT IDENTITY, WORPITZKY'S IDENTITY

### Identity Element

The identity element  $I$  (also denoted  $E$ ,  $e$ , or  $1$ ) of a GROUP or related mathematical structure  $S$  is the unique elements such that  $IA = AI = I$  for every element  $A \in S$ . The symbol " $E$ " derives from the German word for unity, "Einheit."

see also BINARY OPERATOR, GROUP, INVOLUTION (GROUP), MONOID

### Identity Function

The function  $f(x) = x$  which assigns every REAL NUMBER  $x$  to the same REAL NUMBER  $x$ . It is identical to the IDENTITY MAP.

### Identity Map

The MAP which assigns every REAL NUMBER to the same REAL NUMBER  $\text{id}_{\mathbb{R}}$ . It is identical to the IDENTITY FUNCTION.

### Identity Matrix

The identity matrix is defined as the MATRIX 1 (or I) such that

$$I(\mathbf{X}) \equiv \mathbf{X}$$

for all VECTORS  $\mathbf{X}$ . The identity matrix is

$$I_{ij} = \delta_{ij}$$

for  $i, j = 1, 2, \dots, n$ , where  $\delta_{ij}$  is the KRONECKER DELTA. Written explicitly,

$$I = \begin{bmatrix} 1 & 0 & \dots & 0 \\ 0 & 1 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & 1 \end{bmatrix}.$$

### Identity Operator

The OPERATOR  $\tilde{I}$  which takes a REAL NUMBER to the same REAL NUMBER  $\tilde{I}r = r$ .

see also IDENTITY FUNCTION, IDENTITY MAP

### Idoneal Number

A POSITIVE value of  $D$  for which the fact that a number is a MONOMORPH (i.e., the number is expressible in only one way as  $x^2 + Dy^2$  or  $x^2 - Dy^2$  where  $x^2$  is RELATIVELY PRIME to  $Dy^2$ ) guarantees it to be a PRIME, POWER of a PRIME, or twice one of these. The numbers are also called EULER'S IDONEAL NUMBERS, or SUITABLE NUMBERS.

The 65 idoneal numbers found by Gauss and Euler and conjectured to be the *only* such numbers (Shanks 1969) are 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 13, 15, 16, 18, 21, 22, 24, 25, 28, 30, 33, 37, 40, 42, 45, 48, 57, 58, 60, 70, 72, 78, 85, 88, 93, 102, 105, 112, 120, 130, 133, 165, 168, 177, 190, 210, 232, 240, 253, 273, 280, 312, 330, 345, 357, 385, 408, 462, 520, 760, 840, 1320, 1365, and 1848 (Sloane's A000926).

### Iff

If and only if (i.e., NECESSARY and SUFFICIENT). The terms "JUST IF" or "EXACTLY WHEN" are sometimes used instead.  $A$  iff  $B$  is written symbolically as  $A \leftrightarrow B$ .  $A$  iff  $B$  is also equivalent to  $A \Rightarrow B$ , together with  $B \Rightarrow A$ , where the symbol  $\Rightarrow$  denotes "IMPLIES."

J. H. Conway believes that the word originated with P. Halmos and was transmitted through Kelley (1975). Halmos has stated, "To the best of my knowledge, I DID invent the silly thing, but I wouldn't swear to it in a court of law. So there—give me credit for it anyway" (Asimov 1997).

### Ill-Conditioned

A system is ill-conditioned if the CONDITION NUMBER is too large (and singular if it is INFINITE).

see also CONDITION NUMBER

### Illumination Problem

In the early 1950s, Ernst Straus asked

1. Is every POLYGONAL region illuminable from every point in the region?
2. Is every POLYGONAL region illuminable from at least one point in the region?

Here, illuminable means that there is a path from every point to every other by repeated reflections. Tokarsky (1995) showed that unilluminable rooms exist in the plane and 3-D, but question (2) remains open. The smallest known counterexample to (1) in the PLANE has 26 sides.

#### Image

see RANGE (IMAGE)

#### Imaginary Identity

see *i*

#### Imaginary Number

A COMPLEX NUMBER which has zero REAL PART, so that it can be written as a REAL NUMBER multiplied by the "imaginary unit"  $i$  (equal to  $\sqrt{-1}$ ).

see also COMPLEX NUMBER, GALOIS IMAGINARY, GAUSSIAN INTEGER,  $i$ , REAL NUMBER

#### References

- Conway, J. H. and Guy, R. K. *The Book of Numbers*. New York: Springer-Verlag, pp. 211-216, 1996.

#### Imaginary Part

The imaginary part  $\Im$  of a COMPLEX NUMBER  $z = x + iy$  is the REAL NUMBER multiplying  $i$ , so  $\Im[x + iy] = y$ . In terms of  $z$  itself,

$$\Im[z] = \frac{z - z^*}{2i},$$

where  $z^*$  is the COMPLEX CONJUGATE of  $z$ .

#### Imaginary Point

A pair of values  $x$  and  $y$  one or both of which is COMPLEX.

#### References

- Woods, F. S. *Higher Geometry: An Introduction to Advanced Methods in Analytic Geometry*. New York: Dover, p. 2, 1961.

#### Imaginary Quadratic Field

A QUADRATIC FIELD  $\mathbb{Q}(\sqrt{D})$  with  $D < 0$ .

see also QUADRATIC FIELD

#### Immanant

For an  $n \times n$  matrix, let  $S$  denote any permutation  $e_1, e_2, \dots, e_n$  of the set of numbers  $1, 2, \dots, n$ , and let  $\chi^{(\lambda)}(S)$  be the character of the symmetric group corresponding to the partition  $(\lambda)$ . Then the immanant  $|a_{mn}|^{(\lambda)}$  is defined as

$$|a_{mn}|^{(\lambda)} = \sum \chi^{(\lambda)}(S) P_S$$

where the summation is over the  $n!$  permutations of the SYMMETRIC GROUP and

$$P_S = a_{1e_1} a_{2e_2} \cdots a_{ne_n}.$$

#### Immersed Minimal Surface

see ENNEPER'S SURFACES

#### Immersion

A special nonsingular MAP from one MANIFOLD to another such that at every point in the domain of the map, the DERIVATIVE is an injective linear map. This is equivalent to saying that every point in the DOMAIN has a NEIGHBORHOOD such that, up to DIFFEOMORPHISMS of the TANGENT SPACE, the map looks like the inclusion map from a lower-dimensional EUCLIDEAN SPACE to a higher-dimensional EUCLIDEAN SPACE.

see also BOY SURFACE, EVERSION, SMALE-HIRSCH THEOREM

**Impartial Game**

A GAME in which the possible moves are the same for each player in any position. All positions in all impartial GAMES form an additive ABELIAN GROUP. For impartial games in which the last player wins (normal form games), the nim-value of the sum of two GAMES is the nim-sum of their nim-values. If the last player loses, the GAME is said to be in misère form and the analysis is much more difficult.

see also FAIR GAME, GAME, PARTISAN GAME

**Implicit Function**

A function which is not defined explicitly, but rather is defined in terms of an algebraic relationship (which can not, in general, be “solved” for the function in question). For example, the ECCENTRIC ANOMALY  $E$  of a body orbiting on an ELLIPSE with ECCENTRICITY  $e$  is defined implicitly in terms of the mean anomaly  $M$  by KEPLER'S EQUATION

$$M = E - e \sin E.$$

**Implicit Function Theorem**

Given

$$F_1(x, y, z, u, v, w) = 0$$

$$F_2(x, y, z, u, v, w) = 0$$

$$F_3(x, y, z, u, v, w) = 0,$$

if the JACOBIAN

$$JF(u, v, w) = \frac{\partial(F_1, F_2, F_3)}{\partial(u, v, w)} \neq 0,$$

then  $u$ ,  $v$ , and  $w$  can be solved for in terms of  $x$ ,  $y$ , and  $z$  and PARTIAL DERIVATIVES of  $u$ ,  $v$ ,  $w$  with respect to  $x$ ,  $y$ , and  $z$  can be found by differentiating implicitly.

More generally, let  $A$  be an OPEN SET in  $\mathbb{R}^{n+k}$  and let  $f: A \rightarrow \mathbb{R}^n$  be a  $C^r$  FUNCTION. Write  $f$  in the form  $f(x, y)$ , where  $x$  and  $y$  are elements of  $\mathbb{R}^k$  and  $\mathbb{R}^n$ . Suppose that  $(a, b)$  is a point in  $A$  such that  $f(a, b) = 0$  and the DETERMINANT of the  $n \times n$  MATRIX whose elements are the DERIVATIVES of the  $n$  component FUNCTIONS of  $f$  with respect to the  $n$  variables, written as  $y$ , evaluated at  $(a, b)$ , is not equal to zero. The latter may be rewritten as

$$\text{rank}(Df(a, b)) = n.$$

Then there exists a NEIGHBORHOOD  $B$  of  $a$  in  $\mathbb{R}^k$  and a unique  $C^r$  FUNCTION  $g: B \rightarrow \mathbb{R}^n$  such that  $g(a) = b$  and  $f(x, g(x)) = 0$  for all  $x \in B$ .

see also CHANGE OF VARIABLES THEOREM, JACOBIAN

**References**

Munkres, J. R. *Analysis on Manifolds*. Reading, MA: Addison-Wesley, 1991.

**Implies**

The symbol  $\Rightarrow$  means “implies” in the mathematical sense. Let  $A$  be true. If this implies that  $B$  is also true, then the statement is written symbolically as  $A \Rightarrow B$ , or sometimes  $A \subset B$ . If  $A \Rightarrow B$  and  $B \Rightarrow A$  (i.e.,  $A \Rightarrow B \wedge B \Rightarrow A$ ), then  $A$  and  $B$  are said to be EQUIVALENT, a relationship which is written symbolically as  $A \Leftrightarrow B$  or  $A \Rightarrow B$ .

see also EQUIVALENT

**Impossible Figure**

A class of ILLUSION in which an object which is physically unrealizable is apparently depicted.

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Improper Integrals." §4.4 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 135–140, 1992.

## Improper Node

A FIXED POINT for which the STABILITY MATRIX has equal nonzero EIGENVECTORS.

see also STABLE IMPROPER NODE, UNSTABLE IMPROPER NODE

## Improper Rotation

The SYMMETRY OPERATION corresponding to a ROTATION followed by an INVERSION OPERATION, also called a ROTOINVERSION. This operation is denoted  $\bar{n}$  for an improper rotation by  $360^\circ/n$ , so the CRYSTALLOGRAPHY RESTRICTION gives only  $\bar{1}$ ,  $\bar{2}$ ,  $\bar{3}$ ,  $\bar{4}$ ,  $\bar{6}$  for crystals. The MIRROR PLANE symmetry operation is  $(x, y, z) \rightarrow (x, y, -z)$ , etc., which is equivalent to  $\bar{2}$ .

## Impulse Pair

The even impulse pair is the FOURIER TRANSFORM of  $\cos(\pi k)$ ,

$$\Pi(x) \equiv \frac{1}{2}\delta(x + \frac{1}{2}) + \frac{1}{2}\delta(x - \frac{1}{2}). \quad (1)$$

It satisfies

$$\Pi(x) * f(x) = \frac{1}{2}f(x + \frac{1}{2}) + \frac{1}{2}f(x - \frac{1}{2}), \quad (2)$$

where  $*$  denotes CONVOLUTION, and

$$\int_{-\infty}^{\infty} \Pi(x) dx = 1. \quad (3)$$

The odd impulse pair is the FOURIER TRANSFORM of  $i \sin(\pi s)$ ,

$$I_I(x) \equiv \frac{1}{2}\delta(x + \frac{1}{2}) - \frac{1}{2}\delta(x - \frac{1}{2}). \quad (4)$$

## Impulse Symbol

Bracewell's term for the DELTA FUNCTION.

see also IMPULSE PAIR

## References

Bracewell, R. *The Fourier Transform and Its Applications*. New York: McGraw-Hill, 1965.

## In-and-Out Curve

A curve created by starting with a circle, dividing it into six arcs, and flipping three alternating arcs. The process is then repeated an infinite number of times.

## Inaccessible Cardinal

An inaccessible cardinal is a CARDINAL NUMBER which cannot be expressed in terms of a smaller number of smaller cardinals.

## Inaccessible Cardinals Axiom

see also LEBESGUE MEASURABILITY PROBLEM

## Inadmissible

A word or string which is not ADMISSIBLE.

## Incenter

The center  $I$  of a TRIANGLE'S INCIRCLE. It can be found as the intersection of ANGLE BISECTORS, and it is the interior point for which distances to the sidelines are equal. Its TRILINEAR COORDINATES are 1:1:1. The distance between the incenter and CIRCUMCENTER is  $\sqrt{R(R - 2r)}$ .

The incenter lies on the EULER LINE only for an ISOSCELES TRIANGLE. It does, however, lie on the SODDY LINE. For an EQUILATERAL TRIANGLE, the CIRCUMCENTER  $O$ , CENTROID  $G$ , NINE-POINT CENTER  $F$ , ORTHOCENTER  $H$ , and DE LONGCHAMPS POINT  $Z$  all coincide with  $I$ .

The incenter and EXCENTERS of a TRIANGLE are an ORTHOCENTRIC SYSTEM. The POWER of the incenter with respect to the CIRCUMCIRCLE is

$$p = \frac{a_1 a_2 a_3}{a_1 + a_2 + a_3}$$

(Johnson 1929, p. 190). If the incenters of the TRIANGLES  $\Delta A_1 H_2 H_3$ ,  $\Delta A_2 H_3 A_1$ , and  $\Delta A_3 H_1 H_2$  are  $X_1$ ,  $X_2$ , and  $X_3$ , then  $X_2 X_3$  is equal and parallel to  $I_2 I_3$ , where  $H_i$  are the FEET of the ALTITUDES and  $I_i$  are the incenters of the TRIANGLES. Furthermore,  $X_1$ ,  $X_2$ ,  $X_3$ , are the reflections of  $I$  with respect to the sides of the TRIANGLE  $\Delta I_1 I_2 I_3$  (Johnson 1929, p. 193).

If four points are on a CIRCLE (i.e., they are CONCYCLIC), the incenters of the four TRIANGLES form a RECTANGLE whose sides are parallel to the lines connecting the middle points of opposite arcs. Furthermore, the connectors pass through the center of the RECTANGLE (Fuhrmann 1890, p. 50; Johnson 1929, pp. 254–255). More generally, the 16 incenters and excenters of the TRIANGLES whose VERTICES are four points on a CIRCLE, are the intersections of two sets of four PARALLEL lines which are mutually PERPENDICULAR (Johnson 1929, p. 255).

see also CENTROID (ORTHOCENTRIC SYSTEM), CIRCUMCENTER, EXCENTER, GERGONNE POINT, INCIRCLE, INRADIUS, ORTHOCENTER

#### Incenter-Excenter Circle

Given a triangle  $\Delta A_1A_2A_3$ , the points  $A_1$ ,  $I$ , and  $J_1$  lie on a line, where  $I$  is the INCENTER and  $J_1$  is the EXCENTER corresponding to  $A_1$ . Furthermore, the CIRCLE with  $IJ_1$  as the DIAMETER has  $P$  as its center, where  $P$  is the intersection of  $A_1J_1$  with the CIRCUMCIRCLE of  $\Delta A_1A_2A_3$ , and passes through  $A_2$  and  $A_3$ . This CIRCLE has RADIUS

$$r = \frac{1}{2}a_1 \sec(\frac{1}{2}\alpha_1) = 2R \sin(\frac{1}{2}\alpha_1).$$

It arises because  $IJ_1J_2J_3$  forms an ORTHOCENTRIC SYSTEM.

#### Incidence Matrix

For a  $k$ -D POLYTOPE  $\Pi_k$ , the incidence matrix is defined by

$$\eta_{ij}^k = \begin{cases} 1 & \text{if } \Pi_{k-1}^i \text{ belongs to } \Pi_k^j \\ 0 & \text{if } \Pi_{k-1}^i \text{ does not belong to } \Pi_k^j. \end{cases}$$

The  $i$ th row shows which  $\Pi_k$ s surround  $\Pi_{k-1}^i$ , and the  $j$ th column shows which  $\Pi_{k-1}$ s bound  $\Pi_k^j$ . Incidence matrices are also used to specify PROJECTIVE PLANES. The incidence matrices for a TETRAHEDRON  $ABCD$  are

$\eta^0$	1	A	B	C
1	1	1	1	1

$\eta^1$	AD	BD	CD	BC	AC	AB
A	1	0	0	0	1	1
B	0	1	0	1	0	1
C	0	0	1	1	1	0
D	1	1	1	0	0	0

$\eta^2$	BCD	ACD	ABD	ABC
AD	0	1	1	0
BD	1	0	1	0
CD	1	1	0	0
BC	1	0	0	1
AC	0	1	0	1
AB	0	0	1	1

$\eta^3$	ABCD
BCD	1
ACD	1
ABD	1
ABC	1

see also ADJACENCY MATRIX,  $k$ -CHAIN,  $k$ -CIRCUIT

#### Incident

Two objects which touch each other are said to be incident.

see also INCIDENCE MATRIX

## Incircle

The INSCRIBED CIRCLE of a TRIANGLE  $\triangle ABC$ . The center  $I$  is called the INCENTER and the RADIUS  $r$  the INRADIUS. The points of intersection of the incircle with  $T$  are the VERTICES of the PEDAL TRIANGLE of  $T$  with the INCENTER as the PEDAL POINT (c.f. TANGENTIAL TRIANGLE). This TRIANGLE is called the CONTACT TRIANGLE.

The AREA  $K$  of the TRIANGLE  $\triangle ABC$  is given by

$$K = \triangle AIC + \triangle CIB + \triangle AIB \\ = \frac{1}{2}br + \frac{1}{2}ar + \frac{1}{2}cr = \frac{1}{2}(a + b + c)r = sr,$$

where  $s$  is the SEMIPERIMETER.

Using the incircle of a TRIANGLE as the INVERSION CENTER, the sides of the TRIANGLE and its CIRCUMCIRCLE are carried into four equal CIRCLES (Honsberger 1976, p. 21). Pedoe (1995, p. xiv) gives a GEOMETRIC CONSTRUCTION for the incircle.

see also CIRCUMCIRCLE, CONGRUENT INCIRCLES POINT, CONTACT TRIANGLE, INRADIUS, TRIANGLE TRANSFORMATION PRINCIPLE

## Inclusion-Exclusion Principle

If  $A_1, \dots, A_k$  are finite sets, then

$$\left| \bigcup_{i=1}^k A_i \right| = \sum_{i=1}^k (-1)^{i+1} \xi_i,$$

where  $\xi_i$  is the sum of the CARDINALITIES of the intersections of the sets taken  $i$  at a time.

## Inclusion Map

Given a SUBSET  $B$  of a SET  $A$ , the INJECTION  $f: B \rightarrow A$  defined by  $f(b) = b$  for all  $b \in B$  is called the inclusion map.

see also LONG EXACT SEQUENCE OF A PAIR AXIOM

## Incommensurate

Two lengths are called incommensurate or incommensurable if their ratio cannot be expressed as a ratio of whole numbers. IRRATIONAL NUMBERS and TRANSCENDENTAL NUMBERS are incommensurate with the integers.

see also IRRATIONAL NUMBER, PYTHAGORAS'S CONSTANT, TRANSCENDENTAL NUMBER

## Incomplete Gamma Function

see GAMMA FUNCTION

## Incompleteness

A formal theory is said to be incomplete if it contains fewer theorems than would be possible while still retaining CONSISTENCY.

see also CONSISTENCY, GÖDEL'S INCOMPLETENESS THEOREM

## References

- Chaitin, G. J. "G. J. Chaitin's Home Page." <http://www.cs.auckland.ac.nz/CDMTCS/chaitin>.

## Increasing Function

A function  $f(x)$  increases on an INTERVAL  $I$  if  $f(b) > f(a)$  for all  $b > a$ , where  $a, b \in I$ . Conversely, a function  $f(x)$  decreases on an INTERVAL  $I$  if  $f(b) < f(a)$  for all  $b > a$  with  $a, b \in I$ .

If the DERIVATIVE  $f'(x)$  of a CONTINUOUS FUNCTION  $f(x)$  satisfies  $f'(x) > 0$  on an OPEN INTERVAL  $(a, b)$ , then  $f(x)$  is increasing on  $(a, b)$ . However, a function may increase on an interval without having a derivative defined at all points. For example, the function  $x^{1/3}$  is increasing everywhere, including the origin  $x = 0$ , despite the fact that the DERIVATIVE is not defined at that point.

see also DECREASING FUNCTION, DERIVATIVE, NONDECREASING FUNCTION, NONINCREASING FUNCTION

## Increasing Sequence

For a SEQUENCE  $\{a_n\}$ , if  $a_{n+1} - a_n > 0$  for  $n \geq x$ , then  $a$  is increasing for  $n \geq x$ . Conversely, if  $a_{n+1} - a_n < 0$  for  $n \geq x$ , then  $a$  is DECREASING for  $n \geq x$ . If  $a_{n+1}/a_n > 1$  for all  $n \geq x$ , then  $a$  is increasing for  $n \geq x$ . Conversely, if  $a_{n+1}/a_n < 1$  for all  $n \geq x$ , then  $a$  is decreasing for  $n \geq x$ .

## Indefinite Integral

An INTEGRAL

$$\int f(x) dx$$

without upper and lower limits, also called an ANTIDERIVATIVE. The first FUNDAMENTAL THEOREM OF CALCULUS allows DEFINITE INTEGRALS to be computed

in terms of indefinite integrals. If  $F$  is the indefinite integral for  $f(x)$ , then

$$\int_a^b f(x) dx = F(b) - F(a).$$

see also ANTIDERIVATIVE, CALCULUS, DEFINITE INTEGRAL, FUNDAMENTAL THEOREMS OF CALCULUS, INTEGRAL

### Indefinite Quadratic Form

A QUADRATIC FORM  $Q(\mathbf{x})$  is indefinite if it is less than 0 for some values and greater than 0 for others. The QUADRATIC FORM, written in the form  $(\mathbf{x}, A\mathbf{x})$ , is indefinite if EIGENVALUES of the MATRIX  $A$  are of both signs.

see also POSITIVE DEFINITE QUADRATIC FORM, POSITIVE SEMIDEFINITE QUADRATIC FORM

### Indegree

The number of inward directed EDGES from a given VERTEX in a DIRECTED GRAPH.

see also LOCAL DEGREE, OUTDEGREE

### Independence Axiom

A rational choice between two alternatives should depend only on how they differ.

### Independence Complement Theorem

If sets  $E$  and  $F$  are INDEPENDENT, then so are  $E$  and  $F'$ , where  $F'$  is the complement of  $F$  (i.e., the set of all possible outcomes not contained in  $F$ ). Let  $\cup$  denote "or" and  $\cap$  denote "and." Then

$$P(E) = P(EF \cup EF') \quad (1)$$

$$= P(EF) + P(EF') - P(EF \cap EF'), \quad (2)$$

where  $AB$  is an abbreviation for  $A \cap B$ . But  $E$  and  $F$  are independent, so

$$P(EF) = P(E)P(F). \quad (3)$$

Also, since  $F$  and  $F'$  are complements, they contain no common elements, which means that

$$P(EF \cap EF') = 0 \quad (4)$$

for any  $E$ . Plugging (4) and (3) into (2) then gives

$$P(E) = P(E)P(F) + P(EF'). \quad (5)$$

Rearranging,

$$P(EF') = P(E)[1 - P(F)] = P(E)P(F'), \quad (6)$$

Q.E.D.

see also INDEPENDENT STATISTICS

### Independence Number

The number

$$\alpha(G) = \max(|U| : U \subset V \text{ independent})$$

for a GRAPH  $G$ . The independence number of the DE BRUIJN GRAPH of order  $n$  is given by 1, 2, 3, 7, 13, 28, ... (Sloane's A006946).

### Independent Equations

see LINEARLY INDEPENDENT

### Independent Sequence

see STRONGLY INDEPENDENT, WEAKLY INDEPENDENT

### Independent Statistics

Two variates  $A$  and  $B$  are statistically independent IFF the CONDITIONAL PROBABILITY  $P(A|B)$  of  $A$  given  $B$  satisfies

$$P(A|B) = P(A), \quad (1)$$

in which case the probability of  $A$  and  $B$  is just

$$P(AB) = P(A \cap B) = P(A)P(B). \quad (2)$$

Similarly,  $n$  events  $A_1, A_2, \dots, A_n$  are independent IFF

$$P\left(\bigcap_{i=1}^n A_i\right) = \prod_{i=1}^n P(A_i). \quad (3)$$

Statistically independent variables are always UNCORRELATED, but the converse is not necessarily true.

see also BAYES' FORMULA, CONDITIONAL PROBABILITY, INDEPENDENCE COMPLEMENT THEOREM, UNCORRELATED

### Independent Vertices

A set of VERTICES  $A$  of a GRAPH with EDGES  $V$  is independent if it contains no EDGES.

see also INDEPENDENCE NUMBER

### Indeterminate Problems

see DIOPHANTINE EQUATION—LINEAR

### Index

A statistic which assigns a single number to several individual statistics in order to quantify trends. The best-known index in the United States is the consumer price index, which gives a sort of "average" value for inflation based on the price changes for a group of selected products.

Let  $p_n$  be the price per unit in period  $n$ ,  $q_n$  be the quantity produced in period  $n$ , and  $v_n \equiv p_n q_n$  be the value of the  $n$  units. Let  $q_u$  be the estimated relative importance of a product. There are several types of indices defined, among them those listed in the following table.

Index	Abbr.	Formula
Bowley index	$P_B$	$\frac{1}{2}(P_L + P_P)$
Fisher index	$P_F$	$\sqrt{P_L P_P}$
Geometric mean index	$P_G$	$[\prod (\frac{p_n}{p_0})^{v_0}]^{1/\sum v_0}$
Harmonic mean index	$P_H$	$\frac{\sum p_0 q_0}{\sum \frac{p_0^2 q_0}{p_n}}$
Laspeyres's index	$P_L$	$\frac{\sum p_n q_0}{\sum p_0 q_0}$
Marshall-Edgeworth index	$P_{ME}$	$\frac{\sum p_n (q_0 + q_n)}{\sum (v_0 + v_n)}$
Mitchell index	$P_M$	$\frac{\sum p_n q_a}{\sum p_0 q_a}$
Paasche's index	$P_P$	$\frac{\sum p_n q_n}{\sum p_0 q_n}$
Walsh index	$P_W$	$\frac{\sum \sqrt{q_0 q_n} p_n}{\sum \sqrt{q_0 q_n} p_0}$

see also BOWLEY INDEX, FISHER INDEX, GEOMETRIC MEAN INDEX, HARMONIC MEAN INDEX, LASPEYRES' INDEX, MARSHALL-EDGEWORTH INDEX, MITCHELL INDEX, PAASCHE'S INDEX, RESIDUE INDEX, WALSH INDEX

#### Indicatrix

A spherical image of a curve. The most common indicatrix is DUPIN'S INDICATRIX.

see also DUPIN'S INDICATRIX

#### Indicial Equation

The RECURRENCE RELATION obtained during application of the FROBENIUS METHOD of solving a second-order ordinary differential equation. The indicial equation (also called the CHARACTERISTIC EQUATION) is obtained by noting that, by definition, the lowest order term  $x^k$  (that corresponding to  $n = 0$ ) must have a COEFFICIENT of zero. For an example of the construction of an indicial equation, see BESSEL DIFFERENTIAL EQUATION.

1. If the two ROOTS are equal, only one solution can be obtained.
2. If the two ROOTS differ by a noninteger, two solutions can be obtained.
3. If the two ROOTS differ by an INTEGER, the larger will yield a solution. The smaller may or may not.

#### Induction Axiom

The fifth of PEANO'S AXIOMS, which states: If a SET  $S$  of numbers contains zero and also the successor of every number in  $S$ , then every number is in  $S$ .

see also PEANO'S AXIOMS

## Induction Principle

The truth of an INFINITE sequence of propositions  $P_i$  for  $i = 1, \dots, \infty$  is established if (1)  $P_1$  is true, and (2)  $P_k$  IMPLIES  $P_{k+1}$  for all  $k$ .

### References

Courant, R. and Robbins, H. "The Principle of Mathematical Induction" and "Further Remarks on Mathematical Induction." §1.2.1 and 1.7 in *What is Mathematics?: An Elementary Approach to Ideas and Methods*, 2nd ed. Oxford, England: Oxford University Press, pp. 9–11 and 18–20, 1996.

## Inequality

A mathematical statement that one quantity is greater than or less than another. "a is less than b" is denoted  $a < b$ , and "a is greater than b" is denoted  $a > b$ . "a is less than or equal to b" is denoted  $a \leq b$ , and "a is greater than or equal to b" is denoted  $a \geq b$ . The symbols  $a \ll b$  and  $a \gg b$  are used to denote "a is much less than b" and "a is much greater than b," respectively.

Solutions to the inequality  $|x - a| < b$  consist of the set  $\{x : -b < x - a < b\}$ , or equivalently  $\{x : a - b < x < a + b\}$ . Solutions to the inequality  $|x - a| > b$  consist of the set  $\{x : x - a > b\} \cup \{x : x - a < -b\}$ . If  $a$  and  $b$  are both POSITIVE or both NEGATIVE and  $a < b$ , then  $1/a > 1/b$ .

## Inexact Differential

An infinitesimal which is not the differential of an actual function and which cannot be expressed as

$$dz = \left( \frac{\partial z}{\partial x} \right)_y dx + \left( \frac{\partial z}{\partial y} \right)_x dy,$$

the way an EXACT DIFFERENTIAL can. Inexact differentials are denoted with a bar through the  $d$ . The most common example of an inexact differential is the change in heat  $d\bar{Q}$  encountered in thermodynamics.

### Infinary Divisor

$p^x$  is an infinary divisor of  $p^y$  (with  $y > 0$ ) if  $p^x |_{y-1} p^y$ . This generalizes the concept of the  $k$ -ARY DIVISOR.

see also INFINARY PERFECT NUMBER,  $k$ -ARY DIVISOR

### Infinite

Greater than any assignable quantity of the sort in question. In mathematics, the concept of the infinite is made more precise through the notion of an INFINITE SET.

see also COUNTABLE SET, COUNTABLY INFINITE SET, FINITE, INFINITE SET, INFINITESIMAL, INFINITY

### Infinite Product

*N.B. A detailed on-line essay by S. Finch was the starting point for this entry.*

A PRODUCT involving an INFINITE number of terms. Such products can converge. In fact, for POSITIVE  $a_n$ , the PRODUCT  $\prod_{n=1}^{\infty} a_n$  converges to a NONZERO number IFF  $\sum_{n=1}^{\infty} \ln a_n$  converges.

Infinite products can be used to define the COSINE

$$\cos x = \prod_{n=1}^{\infty} \left[ 1 - \frac{4x^2}{\pi^2(2n-1)^2} \right], \quad (1)$$

#### GAMMA FUNCTION

$$\Gamma(z) = \left[ ze^{\gamma z} \prod_{r=1}^{\infty} \left( 1 + \frac{z}{r} \right) e^{-z/r} \right]^{-1}, \quad (2)$$

SINE, and SINC FUNCTION. They also appear in the POLYGON CIRCUMSCRIBING CONSTANT

$$K = \prod_{n=3}^{\infty} \frac{1}{\cos\left(\frac{\pi}{n}\right)}. \quad (3)$$

An interesting infinite product formula due to Euler which relates  $\pi$  and the  $n$ th PRIME  $p_n$  is

$$\pi = \frac{2}{\prod_{i=n}^{\infty} \left[ 1 + \frac{\sin(\frac{1}{2}\pi p_n)}{p_n} \right]} \quad (4)$$

$$= \frac{2}{\prod_{i=n}^{\infty} \left[ 1 + \frac{(-1)^{(p_n-1)/2}}{p_n} \right]} \quad (5)$$

(Blatner 1997).

The product

$$\prod_{n=1}^{\infty} \left( 1 + \frac{1}{n^p} \right) \quad (6)$$

has closed form expressions for small POSITIVE integral  $p \geq 2$ ,

$$\prod_{n=1}^{\infty} \left( 1 + \frac{1}{n^2} \right) = \frac{\sinh \pi}{\pi} \quad (7)$$

$$\prod_{n=1}^{\infty} \left( 1 + \frac{1}{n^3} \right) = \frac{1}{\pi} \cosh\left(\frac{1}{2}\pi\sqrt{3}\right) \quad (8)$$

$$\prod_{n=1}^{\infty} \left( 1 + \frac{1}{n^4} \right) = \frac{\cosh(\pi\sqrt{2}) - \cos(\pi\sqrt{2})}{2\pi^2} \quad (9)$$

$$\prod_{n=1}^{\infty} \left( 1 + \frac{1}{n^5} \right) = \left| \Gamma[\exp(\frac{2}{5}\pi i)] \Gamma[\exp(\frac{6}{5}\pi i)] \right|^{-2}. \quad (10)$$

The  $d$ -ANALOG expression

$$[\infty!]_d = \prod_{n=3}^{\infty} \left( 1 - \frac{2^d}{n^d} \right) \quad (11)$$

also has closed form expressions,

$$\prod_{n=3}^{\infty} \left(1 - \frac{4}{n^2}\right) = \frac{1}{6} \quad (12)$$

$$\prod_{n=3}^{\infty} \left(1 - \frac{8}{n^3}\right) = \frac{\sinh(\pi\sqrt{3})}{42\pi\sqrt{3}} \quad (13)$$

$$\prod_{n=3}^{\infty} \left(1 - \frac{16}{n^4}\right) = \frac{\sinh(2\pi)}{120\pi} \quad (14)$$

$$\prod_{n=3}^{\infty} \left(1 - \frac{32}{n^5}\right) = \left| \Gamma[\exp(\frac{1}{5}\pi i)] \Gamma[2\exp(\frac{7}{5}\pi i)] \right|^{-2}. \quad (15)$$

#### Infinite Series

A SERIES with an INFINITE number of terms.

see also SERIES

#### Infinite Set

A SET of  $S$  elements is said to be infinite if the elements of a PROPER SUBSET  $S'$  can be put into ONE-TO-ONE correspondence with the elements of  $S$ . An infinite set whose elements can be put into a ONE-TO-ONE correspondence with the set of INTEGERS is said to be COUNTABLY INFINITE; otherwise, it is called UNCOUNTABLY INFINITE.

#### Infinitesimal

A quantity which yields 0 after the application of some LIMITING process. The understanding of infinitesimals was a major roadblock to the acceptance of CALCULUS and its placement on a firm mathematical foundation.

see also INFINITE, INFINITY, NONSTANDARD ANALYSIS

#### Infinitesimal Analysis

An archaic term for CALCULUS.

#### Infinitesimal Matrix Change

Let  $B$ ,  $A$ , and  $e$  be square matrices with  $e$  small, and define

$$B \equiv A(I + e), \quad (1)$$

where  $I$  is the IDENTITY MATRIX. Then the inverse of  $B$  is approximately

$$B^{-1} = (I - e)A^{-1}. \quad (2)$$

This can be seen by multiplying

$$\begin{aligned} BB^{-1} &= (A + Ae)(A^{-1} - eA^{-1}) \\ &= AA^{-1} - AeA^{-1} + AeA^{-1} - Ae^2A^{-1} \\ &= I - Ae^2A^{-1} \approx I. \end{aligned} \quad (3)$$

Note that if we instead let  $B' \equiv A + e$ , and look for an inverse of the form  $B'^{-1} = A^{-1} + C$ , we obtain

$$\begin{aligned} B'B'^{-1} &= (A + e)(A^{-1} + C) = AA^{-1} + AC + eA^{-1} + eC \\ &= I + AC + e(C + A^{-1}) \equiv I. \end{aligned} \quad (4)$$

In order to eliminate the  $e$  term, we require  $C = -A^{-1}$ . However, then  $AC = -I$ , so  $BB^{-1} = 0$  so there can be no inverse of this form.

The exact inverse of  $B$  can be found as follows.

$$B = A(I + e) = A(I + A^{-1}e), \quad (5)$$

so

$$B^{-1} = [A(I + A^{-1}e)]^{-1}. \quad (6)$$

Using a general MATRIX INVERSE identity then gives

$$B^{-1} = (I + A^{-1}e)^{-1}A^{-1}. \quad (7)$$

#### Infinitesimal Rotation

An infinitesimal transformation of a VECTOR  $r$  is given by

$$r' = (I + e)r, \quad (1)$$

where the MATRIX  $e$  is infinitesimal and  $I$  is the IDENTITY MATRIX. (Note that the infinitesimal transformation may not correspond to an inversion, since inversion

is a discontinuous process.) The COMMUTATIVITY of infinitesimal transformations  $\mathbf{e}_1$  and  $\mathbf{e}_2$  is established by the equivalence of

$$(\mathbf{I} + \mathbf{e}_1)(\mathbf{I} + \mathbf{e}_2) = \mathbf{I}^2 + \mathbf{e}_1\mathbf{I} + \mathbf{I}\mathbf{e}_2 + \mathbf{e}_1\mathbf{e}_2 \approx \mathbf{I} + \mathbf{e}_1 + \mathbf{e}_2 \quad (2)$$

$$(\mathbf{I} + \mathbf{e}_2)(\mathbf{I} + \mathbf{e}_1) = \mathbf{I}^2 + \mathbf{e}_2\mathbf{I} + \mathbf{I}\mathbf{e}_1 + \mathbf{e}_2\mathbf{e}_1 \approx \mathbf{I} + \mathbf{e}_2 + \mathbf{e}_1. \quad (3)$$

Now let

$$\mathbf{A} \equiv \mathbf{I} + \mathbf{e}. \quad (4)$$

The inverse  $\mathbf{A}^{-1}$  is then  $\mathbf{I} - \mathbf{e}$ , since

$$\mathbf{A}\mathbf{A}^{-1} = (\mathbf{I} + \mathbf{e})(\mathbf{I} - \mathbf{e}) = \mathbf{I}^2 - \mathbf{e}^2 \approx \mathbf{I}. \quad (5)$$

Since we are defining our infinitesimal transformation to be a rotation, ORTHOGONALITY of ROTATION MATRICES requires that

$$\mathbf{A}^T = \mathbf{A}^{-1}, \quad (6)$$

but

$$\mathbf{A}^{-1} = \mathbf{I} - \mathbf{e} \quad (7)$$

$$(\mathbf{I} + \mathbf{e})^T = \mathbf{I}^T + \mathbf{e}^T = \mathbf{I} + \mathbf{e}^T, \quad (8)$$

so  $\mathbf{e} = -\mathbf{e}^T$  and the infinitesimal rotation is ANTISYMMETRIC. It must therefore have a MATRIX of the form

$$\mathbf{e} = \begin{bmatrix} 0 & d\Omega_3 & -d\Omega_2 \\ -d\Omega_3 & 0 & d\Omega_1 \\ d\Omega_2 & -d\Omega_1 & 0 \end{bmatrix}. \quad (9)$$

The differential change in a vector  $\mathbf{r}$  upon application of the ROTATION MATRIX is then

$$d\mathbf{r} \equiv \mathbf{r}' - \mathbf{r} = (\mathbf{I} + \mathbf{e})\mathbf{r} - \mathbf{r} = \mathbf{e}\mathbf{r}. \quad (10)$$

Writing in MATRIX form,

$$d\mathbf{r} = \begin{bmatrix} x \\ y \\ z \end{bmatrix} \begin{bmatrix} 0 & d\Omega_3 & -d\Omega_2 \\ -d\Omega_3 & 0 & d\Omega_1 \\ d\Omega_2 & -d\Omega_1 & 0 \end{bmatrix} = \begin{bmatrix} y d\Omega_3 - z d\Omega_2 \\ z d\Omega_1 - x d\Omega_3 \\ x d\Omega_2 - y d\Omega_1 \end{bmatrix} \quad (11)$$

$$= (y d\Omega_3 - z d\Omega_2)\hat{\mathbf{x}} + (z d\Omega_1 - x d\Omega_3)\hat{\mathbf{y}} + (x d\Omega_2 - y d\Omega_1)\hat{\mathbf{z}} = \mathbf{r} \times d\Omega. \quad (12)$$

Therefore,

$$\left(\frac{d\mathbf{r}}{dt}\right)_{\text{rotation, body}} = \mathbf{r} \times \frac{d\Omega}{dt} = \mathbf{r} \times \boldsymbol{\omega}, \quad (13)$$

where

$$\boldsymbol{\omega} \equiv \frac{d\Omega}{dt} = \dot{\mathbf{n}} \frac{d\phi}{dt}. \quad (14)$$

The total rotation observed in the stationary frame will be a sum of the rotational velocity and the velocity in the rotating frame. However, note that an observer in the stationary frame will see a velocity opposite in direction

to that of the observer in the frame of the rotating body, so

$$\left(\frac{d\mathbf{r}}{dt}\right)_{\text{space}} = \left(\frac{d\mathbf{r}}{dt}\right)_{\text{body}} + \boldsymbol{\omega} \times \mathbf{r}. \quad (15)$$

This can be written as an operator equation, known as the ROTATION OPERATOR, defined as

$$\left(\frac{d}{dt}\right)_{\text{space}} = \left(\frac{d}{dt}\right)_{\text{body}} + \boldsymbol{\omega} \times. \quad (16)$$

see also ACCELERATION, EULER ANGLES, ROTATION, ROTATION MATRIX, ROTATION OPERATOR

### Infinitive Sequence

A sequence  $\{x_n\}$  is called an infinitive sequence if, for every  $i$ ,  $x_n = i$  for infinitely many  $n$ . Write  $a(i, j)$  for the  $j$ th index  $n$  for which  $x_n = i$ . Then as  $i$  and  $j$  range through  $N$ , the array  $A = a(i, j)$ , called the associative array of  $x$ , ranges through all of  $N$ .

see also FRACTAL SEQUENCE

### Infinity

An unbounded number greater than every REAL NUMBER, most often denoted as  $\infty$ . The symbol  $\infty$  had been used as an alternative to M (1,000) in ROMAN NUMERALS until 1655, when John Wallis suggested it be used instead for infinity.

Infinity is a very tricky concept to work with, as evidenced by some of the counterintuitive results which follow from Georg Cantor's treatment of INFINITE SETS. Informally,  $1/\infty = 0$ , a statement which can be made rigorous using the LIMIT concept,

$$\lim_{x \rightarrow \infty} \frac{1}{x} = 0.$$

Similarly,

$$\lim_{x \rightarrow 0^+} \frac{1}{x} = \infty,$$

where the notation  $0^+$  indicates that the LIMIT is taken from the POSITIVE side of the REAL LINE.

### Inflection Point

A point on a curve at which the SIGN of the CURVATURE (i.e., the concavity) changes. The FIRST DERIVATIVE TEST can sometimes distinguish inflection points from EXTREMA for DIFFERENTIABLE functions  $f(x)$ .

see also CURVATURE, DIFFERENTIABLE, EXTREMUM, FIRST DERIVATIVE TEST, STATIONARY POINT

### Information Dimension

Define the "information function" to be

$$I \equiv - \sum_{i=1}^N P_i(\epsilon) \ln[P_i(\epsilon)], \quad (1)$$

where  $P_i(\epsilon)$  is the NATURAL MEASURE, or probability that element  $i$  is populated, normalized such that

$$\sum_{i=1}^N P_i(\epsilon) = 1. \quad (2)$$

The information dimension is then defined by

$$\begin{aligned} d_{\text{inf}} &\equiv - \lim_{\epsilon \rightarrow 0^+} \frac{I}{\ln(\epsilon)} \\ &= \lim_{\epsilon \rightarrow 0^+} \sum_{i=1}^N \frac{P_i(\epsilon) \ln[P_i(\epsilon)]}{\ln(\epsilon)}. \end{aligned} \quad (3)$$

If every element is equally likely to be visited, then  $P_i(\epsilon)$  is independent of  $i$ , and

$$\sum_{i=1}^N P_i(\epsilon) = NP_i(\epsilon) = 1, \quad (4)$$

so

$$P_i(\epsilon) = \frac{1}{N}, \quad (5)$$

and

$$\begin{aligned} d_{\text{inf}} &= \lim_{\epsilon \rightarrow 0^+} \frac{\sum_{i=1}^N \frac{1}{N} \ln\left(\frac{1}{N}\right)}{\ln \epsilon} \\ &= \lim_{\epsilon \rightarrow 0^+} \frac{\ln(N^{-1})}{\ln \epsilon} = - \lim_{\epsilon \rightarrow 0^+} \frac{\ln N}{\ln(\epsilon)} = d_{\text{cap}}, \end{aligned} \quad (6)$$

where  $d_{\text{cap}}$  is the CAPACITY DIMENSION.

### Initial Value Problem

An initial value problem is a problem that has its conditions specified at some time  $t = t_0$ . Usually, the problem is an ORDINARY DIFFERENTIAL EQUATION or a PARTIAL DIFFERENTIAL EQUATION. For example,

$$\begin{cases} \frac{\partial^2 u}{\partial t^2} - \nabla^2 u = f & \text{in } \Omega \\ u = u_0 & t = t_0 \\ u = u_1 & \text{on } \partial\Omega, \end{cases}$$

where  $\partial\Omega$  denotes the boundary of  $\Omega$ , is an initial value problem.

see also BOUNDARY CONDITIONS, BOUNDARY VALUE PROBLEM, PARTIAL DIFFERENTIAL EQUATION

### Injection

see ONE-TO-ONE

**Injective**

A MAP is injective when it is ONE-TO-ONE, i.e.,  $f$  is injective when  $x \neq y$  IMPLIES  $f(x) \neq f(y)$ .

see also ONE-TO-ONE, SURJECTIVE

**Injective Patch**

An injective patch is a PATCH such that  $\mathbf{x}(u_1, v_1) = \mathbf{x}(u_2, v_2)$  implies that  $u_1 = u_2$  and  $v_1 = v_2$ . An example of a PATCH which is injective but not REGULAR is the function defined by  $(u^3, v^3, uv)$  for  $u, v \in (-1, 1)$ . However, if  $\mathbf{x} : U \rightarrow \mathbb{R}^n$  is an injective regular patch, then  $\mathbf{x}$  maps  $U$  diffeomorphically onto  $\mathbf{x}(U)$ .

see also PATCH, REGULAR PATCH

Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, p. 187, 1993.

**Inner Automorphism Group**

A particular type of AUTOMORPHISM GROUP which exists only for GROUPS. For a GROUP  $G$ , the inner automorphism group is defined by

$$\text{Inn}(G) = \{\sigma_a : a \in G\} \subset \text{Aut}(G)$$

where  $\sigma_a$  is an AUTOMORPHISM of  $G$  defined by

$$\sigma_a(x) = axa^{-1}.$$

see also AUTOMORPHISM, AUTOMORPHISM GROUP

**Inner Product**

see DOT PRODUCT

**Inner Product Space**

An inner product space is a VECTOR SPACE which has an INNER PRODUCT. If the INNER PRODUCT defines a NORM, then the inner product space is called a HILBERT SPACE.

see also HILBERT SPACE, INNER PRODUCT, NORM

**Inradius**

The radius of a TRIANGLE'S INCIRCLE or of a POLYHEDRON'S INSHERE, denoted  $r$ . For a TRIANGLE,

$$r = \frac{1}{2} \sqrt{\frac{(b+c-a)(c+a-b)(a+b-c)}{a+b+c}} = \frac{\Delta}{s} \quad (1)$$

$$= 4R \sin(\tfrac{1}{2}\alpha_1) \sin(\tfrac{1}{2}\alpha_2) \sin(\tfrac{1}{2}\alpha_3), \quad (2)$$

where  $\Delta$  is the AREA of the TRIANGLE,  $a$ ,  $b$ , and  $c$  are the side lengths,  $s$  is the SEMIPERIMETER, and  $R$  is the CIRCUMRADIUS (Johnson 1929, p. 189).

Equation (1) can be derived easily using TRILINEAR COORDINATES. Since the INCENTER is equally spaced from all three sides, its trilinear coordinates are 1:1:1, and its exact trilinear coordinates are  $r : r : r$ . The ratio  $k$  of

the exact trilinears to the homogeneous coordinates is given by

$$k = \frac{2\Delta}{a+b+c} = \frac{\Delta}{s}. \quad (3)$$

But since  $k = r$  in this case,

$$r = k = \frac{\Delta}{s}, \quad (4)$$

Q. E. D.

Other equations involving the inradius include

$$Rr = \frac{abc}{4s} \quad (5)$$

$$\Delta^2 = rr_1r_2r_3 \quad (6)$$

$$\cos A + \cos B + \cos C = 1 + \frac{r}{R} \quad (7)$$

$$r = 2R \cos A \cos B \cos C \quad (8)$$

$$a^2 + b^2 + c^2 = 4rR + 8R^2, \quad (9)$$

where  $r_i$  are the EXRADII (Johnson 1929, pp. 189–191).

As shown in RIGHT TRIANGLE, the inradius of a RIGHT TRIANGLE of integral side lengths  $x$ ,  $y$ , and  $z$  is also integral, and is given by

$$r = \frac{xy}{x+y+z}, \quad (10)$$

where  $z$  is the HYPOTENUSE. Let  $d$  be the distance between inradius  $r$  and CIRCUMRADIUS  $R$ ,  $d = \overline{rR}$ . Then

$$R^2 - d^2 = 2Rr \quad (11)$$

$$\frac{1}{R-d} + \frac{1}{R+d} = \frac{1}{r} \quad (12)$$

(Mackay 1886–87). These and many other identities are given in Johnson (1929, pp. 186–190).

Expressing the MIDRADIUS  $\rho$  and CIRCUMRADIUS  $R$  in terms of the midradius gives

$$r = \frac{\rho^2}{\sqrt{\rho^2 + \frac{1}{4}a^2}} \quad (13)$$

$$r = \frac{R^2 - \frac{1}{4}a^2}{R} \quad (14)$$

for an ARCHIMEDEAN SOLID.

**Instrument Function**

The finite FOURIER COSINE TRANSFORM of an APODIZATION FUNCTION, also known as an APPARATUS FUNCTION. The instrument function  $I(k)$  corresponding to a given APODIZATION FUNCTION  $A(x)$  is then given by

$$I(k) = \int_{-a}^a \cos(2\pi kx) A(x) dx.$$

see also APODIZATION FUNCTION, FOURIER COSINE TRANSFORM

**Insufficient Reason Principle**

A principle also called the INDIFFERENCE PRINCIPLE which was first enunciated by Johann Bernoulli. The insufficient reason principle states that, if we are ignorant of the ways an event can occur and therefore have no reason to believe that one way will occur preferentially to another, it will occur equally likely in any way.

**Int**

see INTEGER PART

**Integer**

One of the numbers  $\dots, -2, -1, 0, 1, 2, \dots$ . The SET of INTEGERS forms a RING which is denoted  $\mathbb{Z}$ . A given INTEGER  $n$  may be NEGATIVE ( $n \in \mathbb{Z}^-$ ), NONNEGATIVE ( $n \in \mathbb{Z}^*$ ), ZERO ( $n = 0$ ), or POSITIVE ( $n \in \mathbb{Z}^+ = \mathbb{N}$ ). The RING  $\mathbb{Z}$  has CARDINALITY of  $\aleph_0$ . The GENERATING FUNCTION for the POSITIVE INTEGERS is

$$f(x) = \frac{1}{(1-x)^2} = x + 2x^2 + 3x^3 + 4x^4 + \dots$$

There are several symbols used to perform operations having to do with conversion between REAL NUMBERS and integers. The symbol  $\lfloor x \rfloor$  ("FLOOR  $x$ ") means "the largest integer not greater than  $x$ ," i.e.,  $\text{int}(x)$  in computer parlance. The symbol  $\lceil x \rceil$  means "the nearest integer to  $x$ " (NINT), i.e.,  $\text{nint}(x)$  in computer parlance. The symbol  $\lceil x \rceil$  ("CEILING  $x$ ") means "the smallest integer not smaller than  $x$ ," or  $-\text{int}(-x)$ , where  $\text{int}(x)$  is the INTEGER PART of  $x$ .

see also ALGEBRAIC INTEGER, ALMOST INTEGER, COMPLEX NUMBER, COUNTING NUMBER, CYCLOTOMIC INTEGER, EISENSTEIN INTEGER, GAUSSIAN INTEGER,  $\mathbb{N}$ , NATURAL NUMBER, NEGATIVE, POSITIVE, RADICAL INTEGER, REAL NUMBER, WHOLE NUMBER,  $\mathbb{Z}$ ,  $\mathbb{Z}^-$ ,  $\mathbb{Z}^+$ ,  $\mathbb{Z}^*$ , ZERO

**Integer Division**

DIVISION in which the fractional part (remainder) is discarded is called integer division and is sometimes denoted  $\backslash$ . Integer division can be defined as  $a \backslash b \equiv \lfloor a/b \rfloor$ , where  $/$  denotes normal division and  $\lfloor x \rfloor$  is the FLOOR FUNCTION. For example,

$$10/3 = 3 + 1/3$$

$$10 \backslash 3 = 3.$$

**Integer Factorization**

see PRIME FACTORIZATION

**Integer-Matrix Form**

Let  $Q(x) \equiv Q(\mathbf{x}) = Q(x_1, x_2, \dots, x_n)$  be an integer-valued  $n$ -ary QUADRATIC FORM, i.e., a POLYNOMIAL with integer COEFFICIENTS which satisfies  $Q(x) > 0$  for REAL  $x \neq 0$ . Then  $Q(x)$  can be represented by

$$Q(x) = \mathbf{x}^T \mathbf{A} \mathbf{x},$$

where

$$\mathbf{A} = \frac{1}{2} \frac{\partial^2 Q(x)}{\partial x_i \partial x_j}$$

is a POSITIVE symmetric matrix (Duke 1997). If  $A$  has POSITIVE entries, then  $Q(x)$  is called an integer matrix form. Conway *et al.* (1997) have proven that, if a POSITIVE integer matrix quadratic form represents each of 1, 2, 3, 5, 6, 7, 10, 14, and 15, then it represents all POSITIVE INTEGERS.

see also FIFTEEN THEOREM

## Integer Module

see ABELIAN GROUP

## Integer Part

The function  $\text{int}(x)$  gives the INTEGER PART of  $x$ . In many computer languages, the function is denoted  $\text{int}(x)$ , but in mathematics, it is usually called the FLOOR FUNCTION and denoted  $\lfloor x \rfloor$ .

see also CEILING FUNCTION, FLOOR FUNCTION, NINT

## Integer Relation

A set of REAL NUMBERS  $x_1, \dots, x_n$  is said to possess an integer relation if there exist integers  $a_i$  such that

$$a_1x_1 + a_2x_2 + \dots + a_nx_n = 0,$$

with not all  $a_i = 0$ . An interesting example of such a relation is the 17-VECTOR  $(1, x, x^2, \dots, x^{16})$  with  $x = 3^{1/4} - 2^{1/4}$ , which has an integer relation  $(1, 0, 0, 0, -3860, 0, 0, 0, -666, 0, 0, 0, -20, 0, 0, 0, 1)$ , i.e.,

$$1 - 3860x^4 - 666x^8 - 20x^{12} + x^{16} = 0.$$

This is a special case of finding the polynomial of degree  $n = rs$  satisfied by  $x = 3^{1/r} - 2^{1/s}$ .

Algorithms for finding integer relations include the FERGUSON-FORCADE ALGORITHM, HJLS ALGORITHM, LLL ALGORITHM, PSLQ ALGORITHM, PSOS ALGORITHM, and the algorithm of Lagarias and Odlyzko (1985). Perhaps the simplest (and unfortunately most inefficient) such algorithm is the GREEDY ALGORITHM. Plouffe's "Inverse Symbolic Calculator" site includes a huge 54 million database of REAL NUMBERS which are algebraically related to fundamental mathematical constants.

## Integer Sequence

A SEQUENCE whose terms are INTEGERS. The most complete printed references for such sequences are Sloane (1973) and its update, Sloane and Plouffe (1995). Sloane also maintains the sequences from both works together with many additional sequences in an on-line listing. In this listing, sequences are identified by a unique 6-DIGIT A-number. Sequences appearing in Sloane and Plouffe (1995) are ordered lexicographically and identified with a 4-DIGIT M-number, and those appearing in Sloane (1973) are identified with a 4-DIGIT N-number.

Sloane's huge (and enjoyable) database is accessible by either e-mail or web browser. To look up sequences by e-mail, send a message to either [sequences@research.att.com](mailto:sequences@research.att.com) or [superseeker@research.att.com](mailto:superseeker@research.att.com) containing lines of the form `lookup 5 14 42 132 ....`. To use the browser version, point to <http://www.research.att.com/~njas/sequences/eisonline.html>.

## Integrable

A function for which the INTEGRAL can be computed is said to be integrable.

see also DIFFERENTIABLE, INTEGRAL, INTEGRATION

## Integral

An integral is a mathematical object which can be interpreted as an AREA or a generalization of AREA. Integrals, together with DERIVATIVES, are the fundamental objects of CALCULUS. Other words for integral include ANTIDERIVATIVE and PRIMITIVE. The RIEMANN INTEGRAL is the simplest integral definition and the only one usually encountered in elementary CALCULUS. The RIEMANN INTEGRAL of the function  $f(x)$  over  $x$  from  $a$  to  $b$  is written

$$\int_a^b f(x) dx. \quad (1)$$

Every definition of an integral is based on a particular MEASURE. For instance, the RIEMANN INTEGRAL is based on JORDAN MEASURE, and the LEBESGUE INTEGRAL is based on LEBESGUE MEASURE. The process of computing an integral is called INTEGRATION (a more archaic term for INTEGRATION is QUADRATURE), and the approximate computation of an integral is termed NUMERICAL INTEGRATION.

There are two classes of (Riemann) integrals: DEFINITE INTEGRALS

$$\int_a^b f(x) dx, \quad (2)$$

which have upper and lower limits, and INDEFINITE INTEGRALS, which are written without limits. The first FUNDAMENTAL THEOREM OF CALCULUS allows DEFINITE INTEGRALS to be computed in terms of INDEFINITE

INTEGRALS, since if  $F$  is the INDEFINITE INTEGRAL for  $f(x)$ , then

$$\int_a^b f(x) dx = F(b) - F(a). \quad (3)$$

Wolfram Research (<http://www.integrals.com>) maintains a web site which will integrate many common (and not so common) functions. However, it cannot solve some simple integrals such as

$$\begin{aligned} \int \left[ \frac{d}{dx} (x\sqrt{\sin x}) \right] dx \\ = \int \left( \frac{x \cos x}{2\sqrt{\sin x}} + \sqrt{\sin x} \right) dx \end{aligned} \quad (4)$$

$$\begin{aligned} \int \left[ \frac{d}{dx} L_2(x \ln x) \right] dx \\ = - \int \left[ \frac{(\ln x + 1) \ln(1 - x \ln x)}{x \ln x} \right] dx, \end{aligned} \quad (5)$$

where  $L_2$  is the DILOGARITHM. Furthermore, it gives an incorrect answer of  $\pi^{1-2\sqrt{3}}/(\sqrt{3} \cdot 4^{\sqrt{3}})$  to

$$I(\sqrt{3}) = \int_0^{\pi/2} \frac{dx}{1 + (\tan x)^{\sqrt{3}}} = \frac{1}{2}\pi. \quad (6)$$

This integral and, in fact, the generalized integral for arbitrary  $a$

$$I(a) = \int_0^{\pi/2} \frac{dx}{1 + (\tan x)^a}, \quad (7)$$

have a "trick" solution which takes advantage of the trigonometric identity

$$\tan\left(\frac{1}{2}\pi - x\right) = \cot x. \quad (8)$$

Letting  $z \equiv (\tan x)^a$ ,

$$\begin{aligned} I(a) &= \int_0^{\pi/4} \frac{dx}{1+z} + \int_{\pi/4}^{\pi/2} \frac{dx}{1+z} \\ &= \int_0^{\pi/4} \frac{dx}{1+z} + \int_0^{\pi/4} \frac{dx}{1+\frac{1}{z}} \\ &= \int_0^{\pi/4} \left( \frac{1}{1+z} + \frac{1}{1+\frac{1}{z}} \right) dx = \int_0^{\pi/4} dx \\ &= \frac{1}{4}\pi. \end{aligned} \quad (9)$$

Here is a list of common INDEFINITE INTEGRALS:

$$\int x^r dx = \frac{x^{r+1}}{r+1} + C \quad (10)$$

$$\int \frac{dx}{x} = \ln|x| + C \quad (11)$$

$$\int a^x dx = \frac{a^x}{\ln a} + C \quad (12)$$

$$\int \sin x dx = -\cos x + C \quad (13)$$

$$\int \cos x dx = \sin x + C \quad (14)$$

$$\int \tan x dx = \ln|\sec x| + C \quad (15)$$

$$\int \csc x dx = \ln|\csc x - \cot x| + C \quad (16)$$

$$= \ln\left[\tan\left(\frac{1}{2}x\right)\right] + C \quad (17)$$

$$= \frac{1}{2} \ln\left(\frac{1 - \cos x}{1 + \cos x}\right) + C \quad (18)$$

$$\int \sec x dx = \ln|\sec x + \tan x| + C$$

$$= \operatorname{gd}^{-1}(x) + C \quad (19)$$

$$\int \cot x dx = \ln|\sin x| + C \quad (20)$$

$$\int \sec^2 x dx = \tan x + C \quad (21)$$

$$\int \csc^2 x dx = -\cot x + C \quad (22)$$

$$\int \sec x \tan x dx = \sec x + C \quad (23)$$

$$\int \cos^{-1} x dx = x \cos^{-1} x - \sqrt{1-x^2} + C \quad (24)$$

$$\int \sin^{-1} x dx = x \sin^{-1} x + \sqrt{1-x^2} + C \quad (25)$$

$$\int \tan^{-1} x dx = x \tan^{-1} x - \frac{1}{2} \ln(1+x^2) + C \quad (26)$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\left(\frac{x}{a}\right) + C \quad (27)$$

$$\int \frac{dx}{\sqrt{a^2 + x^2}} = \cos^{-1}\left(\frac{x}{a}\right) + C \quad (28)$$

$$\int \frac{dx}{a^2 + x^2} = \frac{1}{a} \tan^{-1}\left(\frac{x}{a}\right) + C \quad (29)$$

$$\int \frac{dx}{a^2 - x^2} = -\frac{1}{a} \cot^{-1}\left(\frac{x}{a}\right) + C \quad (30)$$

$$\int \frac{dx}{x\sqrt{x^2 - a^2}} = \frac{1}{a} \sec^{-1}\left(\frac{x}{a}\right) + C \quad (31)$$

$$\int \frac{dx}{x\sqrt{x^2 + a^2}} = -\frac{1}{a} \csc^{-1}\left(\frac{x}{a}\right) + C \quad (32)$$

$$\int \sin^2(ax) dx = \frac{x}{2} - \frac{1}{4a} \sin(2ax) + C \quad (33)$$

$$\int \operatorname{sn} u du = k^{-1} \ln(\operatorname{dn} u - k \operatorname{cn} u) + C \quad (34)$$

$$\int \operatorname{sn}^2 u du = \frac{u - E(u)}{k^2} + C \quad (35)$$

$$\int \operatorname{cn} u du = k^{-1} \sin^{-1}(k \operatorname{sn} u) + C \quad (36)$$

$$\int \operatorname{dn} u du = \sin^{-1}(\operatorname{sn} u) + C, \quad (37)$$

where  $\sin x$  is the SINE;  $\cos x$  is the COSINE;  $\tan x$  is the TANGENT;  $\csc x$  is the COSECANT;  $\sec x$  is the SECANT;  $\cot x$  is the COTANGENT;  $\cos^{-1} x$  is the INVERSE COSINE;  $\sin^{-1} x$  is the INVERSE SINE;  $\tan^{-1}$  is the INVERSE TANGENT;  $\operatorname{sn} u$ ,  $\operatorname{cn} u$ , and  $\operatorname{dn} u$  are JACOBI ELLIPTIC FUNCTIONS;  $E(u)$  is a complete ELLIPTIC INTEGRAL OF THE SECOND KIND; and  $\operatorname{gd}(x)$  is the GUDERMANNIAN FUNCTION.

To derive (15), let  $u \equiv \cos x$ , so  $du = -\sin x dx$  and

$$\int \tan x = \int \frac{\sin x}{\cos x} dx = -\int \frac{du}{u}$$

$$= -\ln|u| + C = -\ln|\cos x| + C$$

$$= \ln|\cos x|^{-1} + C = \ln|\sec x| + C. \quad (38)$$

To derive (18), let  $u \equiv \csc x - \cot x$ , so  $du = (-\csc x \cot x + \csc^2 x) dx$  and

$$\int \csc x dx = \int \csc x \frac{\csc x - \cot x}{\csc x - \cot x} dx$$

$$= \int \frac{\csc^2 x + \cot x \csc x}{\csc x + \cot x} dx$$

$$= \int \frac{du}{u} = \ln|u| + C$$

$$= \ln|\csc x - \cot x| + C. \quad (39)$$

To derive (19), let

$$u \equiv \sec x + \tan x, \quad (40)$$

so

$$du = (\sec x \tan x + \sec^2 x) dx \quad (41)$$

and

$$\int \sec x dx = \int \sec x \frac{\sec x + \tan x}{\sec x + \tan x} dx$$

$$= \int \frac{\sec^2 x + \sec x \tan x}{\sec x + \tan x} dx$$

$$= \int \frac{du}{u} = \ln|u| + C$$

$$= \ln|\sec x + \tan x| + C. \quad (42)$$

To derive (20), let  $u \equiv \sin x$ , so  $du = \cos x dx$  and

$$\begin{aligned}\int \cot x dx &= \int \frac{\cos x}{\sin x} dx = \int \frac{du}{u} \\ &= \ln |u| + C = \ln |\sin x| + C.\end{aligned}\quad (43)$$

Differentiating integrals leads to some useful and powerful identities, for instance

$$\frac{d}{dx} \int_a^x f(x) dx = f(x), \quad (44)$$

which is the first FUNDAMENTAL THEOREM OF CALCULUS.

$$\frac{d}{dx} \int_x^b f(x) dx = -f(x) \quad (45)$$

$$\frac{d}{dx} \int_a^b f(x, t) dt = \int_a^b \frac{\partial}{\partial x} f(x, t) dt \quad (46)$$

$$\frac{d}{dx} \int_a^x f(x, t) dt = f(x, t) + \int_a^x \frac{\partial}{\partial x} f(x, t) dt. \quad (47)$$

If  $f(x, t)$  is singular or INFINITE, then

$$\begin{aligned}\frac{d}{dx} \int_a^x f(x, t) dx \\ = \frac{1}{x-a} \int_a^x \left[ (x-a) \frac{\partial f}{\partial x} + (t-a) \frac{\partial f}{\partial t} + f \right] dt.\end{aligned}\quad (48)$$

The LEIBNIZ IDENTITY is

$$\begin{aligned}\frac{d}{dx} \int_{u(x)}^{v(x)} f(x, t) dt &= v'(x) f(x, v(x)) - u'(x) f(x, u(x)) \\ &\quad + \int_{u(x)}^{v(x)} \frac{\partial}{\partial x} f(x, t) dt.\end{aligned}\quad (49)$$

Other integral identities include

$$\int_a^x \int_a^x f(t) dt dx = \int_a^x (x-t) f(t) dt \quad (50)$$

$$\begin{aligned}\int_0^x dt_n \int_0^{t_n} dt_{n-1} \cdots \int_0^{t_3} dt_2 \int_0^{t_2} f(t_1) dt_1 \\ = \frac{1}{(n-1)!} \int_0^x (x-t)^{n-1} f(t) dt\end{aligned}\quad (51)$$

$$\frac{\partial}{\partial x_k} (x_j J_k) = \delta_{jk} J_k + x_j \frac{\partial}{\partial x_k} J_k = \mathbf{J} + \mathbf{r} \nabla \cdot \mathbf{J} \quad (52)$$

$$\begin{aligned}\int_V \mathbf{J} d^3 \mathbf{r} &= \int_V \frac{\partial}{\partial x_k} (x_i J_k) - \int_V \mathbf{r} \nabla \cdot \mathbf{J} d^3 \mathbf{r} \\ &= - \int_V \mathbf{r} \nabla \cdot \mathbf{J} d^3 \mathbf{r}.\end{aligned}\quad (53)$$

Integrals of the form

$$\int_a^b f(x) dx \quad (54)$$

with one INFINITE LIMIT and the other NONZERO may be expressed as finite integrals over transformed functions. If  $f(x)$  decreases at least as fast as  $1/x^2$ , then let

$$t \equiv \frac{1}{x} \quad (55)$$

$$dt = -\frac{dx}{x^2} \quad (56)$$

$$dx = -x^2 dt = -\frac{dt}{t^2}, \quad (57)$$

and

$$\int_a^b f(x) dx = - \int_{1/b}^{1/a} \frac{1}{t^2} f\left(\frac{1}{t}\right) dt = \int_{1/b}^{1/a} \frac{1}{t^2} f\left(\frac{1}{t}\right) dt. \quad (58)$$

If  $f(x)$  diverges as  $(x-a)^\gamma$  for  $\gamma \in [0, 1]$ , let

$$x \equiv t^{1/(1-\gamma)} + a \quad (59)$$

$$\begin{aligned}dx &= \frac{1}{1-\gamma} t^{(1/(1-\gamma))-1} dt = \frac{1}{1-\gamma} t^{[1-(1-\gamma)]/(1-\gamma)} dt \\ &= \frac{1}{\gamma-1} t^{\gamma/(1-\gamma)} dt\end{aligned}\quad (60)$$

$$t = (x-a)^{1-\gamma}, \quad (61)$$

and

$$\begin{aligned}\int_a^b f(x) dx &= \frac{1}{1-\gamma} \\ &= \int_0^{(b-a)^{1-\gamma}} t^{\gamma/(1-\gamma)} f(t^{1/(1-\gamma)} + a) dt.\end{aligned}\quad (62)$$

If  $f(x)$  diverges as  $(x+b)^\gamma$  for  $\gamma \in [0, 1]$ , let

$$x \equiv b - t^{1/(1-\gamma)} \quad (63)$$

$$dx = -\frac{1}{\gamma-1} t^{\gamma/(1-\gamma)} dt \quad (64)$$

$$t = (b-x)^{1-\gamma}, \quad (65)$$

and

$$\begin{aligned}\int_a^b f(x) dx &= \frac{1}{1-\gamma} \\ &= \int_0^{(b-a)^{1-\gamma}} t^{\gamma/(1-\gamma)} f(b - t^{1/(1-\gamma)}) dt.\end{aligned}\quad (66)$$

If the integral diverges exponentially, then let

$$t \equiv e^{-x} \quad (67)$$

$$dt = -e^{-x} dx \quad (68)$$

$$x = -\ln t, \quad (69)$$

and

$$\int_a^\infty f(x) dx = \int_0^{e^{-a}} f(-\ln t) \frac{dt}{t}. \quad (70)$$

Integrals with rational exponents can often be solved by making the substitution  $u = x^{1/n}$ , where  $n$  is the LEAST COMMON MULTIPLE of the DENOMINATOR of the exponents.

Integration rules include

$$\int_a^a f(x) dx = 0 \quad (71)$$

$$\int_a^b f(x) dx = - \int_b^a f(x) dx. \quad (72)$$

For  $c \in (a, b)$ ,

$$\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx. \quad (73)$$

If  $g'$  is continuous on  $[a, b]$  and  $f$  is continuous and has an antiderivative on an INTERVAL containing the values of  $g(x)$  for  $a \leq x \leq b$ , then

$$\int_a^b f(g(x))g'(x) dx = \int_{g(a)}^{g(b)} f(u) du. \quad (74)$$

Liouville showed that the integrals

$$\int e^{-x^2} dx \quad \int \frac{e^x}{x} dx \quad \int \frac{\sin x}{x} dx \quad \int \frac{dx}{\ln x} \quad (75)$$

cannot be expressed as terms of a finite number of elementary functions. Other irreducibles include

$$\int x^x dx \quad \int x^{-x} dx \quad \int \sqrt{\sin x} dx. \quad (76)$$

Chebyshev proved that if  $U$ ,  $V$ , and  $W$  are RATIONAL NUMBERS, then

$$\int x^U (A + Bx^V)^W dx \quad (77)$$

is integrable in terms of elementary functions IFF  $(U + 1)/V$ ,  $W$ , or  $W + (U + 1)/V$  is an INTEGER (Ritt 1948, Shanks 1993).

There are a wide range of methods available for NUMERICAL INTEGRATION. A good source for such techniques is Press *et al.* (1992). The most straightforward numerical integration technique uses the NEWTON-COTES FORMULAS (also called QUADRATURE FORMULAS), which approximate a function tabulated at a sequence of regularly spaced INTERVALS by various degree POLYNOMIALS. If the endpoints are tabulated, then the 2- and 3-point formulas are called the TRAPEZOIDAL RULE and

SIMPSON'S RULE, respectively. The 5-point formula is called BODE'S RULE. A generalization of the TRAPEZOIDAL RULE is ROMBERG INTEGRATION, which can yield accurate results for many fewer function evaluations.

If the analytic form of a function is known (instead of its values merely being tabulated at a fixed number of points), the best numerical method of integration is called GAUSSIAN QUADRATURE. By picking the optimal ABSCISSAS at which to compute the function, Gaussian quadrature produces the most accurate approximations possible. However, given the speed of modern computers, the additional complication of the GAUSSIAN QUADRATURE formalism often makes it less desirable than the brute-force method of simply repeatedly calculating twice as many points on a regular grid until convergence is obtained. An excellent reference for GAUSSIAN QUADRATURE is Hildebrand (1956).

### Integral Brick

see EULER BRICK

### Integral Calculus

That portion of “the” CALCULUS dealing with INTEGRALS.

see also CALCULUS, DIFFERENTIAL CALCULUS, INTEGRAL

### Integral Cuboid

see EULER BRICK

### Integral Current

A RECTIFIABLE CURRENT whose boundary is also a RECTIFIABLE CURRENT.

### Integral Curvature

Given a GEODESIC TRIANGLE (a triangle formed by the arcs of three GEODESICS on a smooth surface),

$$\int_{ABC} K \, da = A + B + C - \pi.$$

Given the EULER CHARACTERISTIC  $\chi$ ,

$$\iint K \, da = 2\pi\chi,$$

so the integral curvature of a closed surface is not altered by a topological transformation.

see also GAUSS-BONNET FORMULA, GEODESIC TRIANGLE

### Integral Domain

A RING that is COMMUTATIVE under multiplication, has a unit element, and has no divisors of 0. The INTEGERS form an integral domain.

see also FIELD, RING

### Integral Drawing

A GRAPH drawn such that the EDGES have only INTEGER lengths. It is conjectured that every PLANAR GRAPH has an integral drawing.

### References

Harborth, H. and Möller, M. “Minimum Integral Drawings of the Platonic Graphs.” *Math. Mag.* **67**, 355–358, 1994.

### Integral Equation

If the limits are fixed, an integral equation is called a Fredholm integral equation. If one limit is variable, it is called a Volterra integral equation. If the unknown function is only under the integral sign, the equation is said to be of the “first kind.” If the function is both inside and outside, the equation is called of the “second kind.” A Fredholm equation of the first kind is of the form

$$f(x) = \int_a^b K(x, t)\phi(t) \, dt. \quad (1)$$

A Fredholm equation of the second kind is of the form

$$\phi(x) = f(x) + \lambda \int_a^b K(x, t)\phi(t) \, dt. \quad (2)$$

A Volterra equation of the first kind is of the form

$$f(x) = \int_a^x K(x, t)\phi(t) \, dt. \quad (3)$$

A Volterra equation of the second kind is of the form

$$\phi(x) = f(x) + \int_a^x K(x, t)\phi(t) \, dt, \quad (4)$$

where the functions  $K(x, t)$  are known as KERNELS. Integral equations may be solved directly if they are SEPARABLE. Otherwise, a NEUMANN SERIES must be used.

A KERNEL is separable if

$$K(x, t) = \lambda \sum_{j=1}^n M_j(x)N_j(t). \quad (5)$$

This condition is satisfied by all POLYNOMIALS and many TRANSCENDENTAL FUNCTIONS. A FREDHOLM INTEGRAL EQUATION OF THE SECOND KIND with separable KERNEL may be solved as follows:

$$\begin{aligned} \phi(x) &= f(x) + \int_a^b K(x, t)\phi(t) \, dt \\ &= f(x) + \lambda \sum_{j=1}^n M_j(x) \int_a^b N_j(t)\phi(t) \, dt \\ &= f(x) + \lambda \sum_{j=1}^n c_j M_j(x), \end{aligned} \quad (6)$$

where

$$c_j \equiv \int_a^b N_j(t)\phi(t) \, dt. \quad (7)$$

Now multiply both sides of (7) by  $N_i(x)$  and integrate over  $dx$ .

$$\begin{aligned} &\int_a^b \phi(x)N_i(x) \, dx \\ &= \int_a^b f(x)N_i(x) \, dx + \lambda \sum_{j=1}^n c_j \int_a^b M_j(x)N_i(x) \, dx. \end{aligned} \quad (8)$$

By (7), the first term is just  $c_i$ . Now define

$$b_i \equiv \int_a^b N_i(x) f(x) dx \quad (9)$$

$$a_{ij} = \int_a^b N_i(x) M_j(x) dx, \quad (10)$$

so (8) becomes

$$c_i = b_i + \lambda \sum_{j=1}^n a_{ij} c_j. \quad (11)$$

Writing this in matrix form,

$$\mathbf{C} = \mathbf{B} + \lambda \mathbf{A} \mathbf{C}, \quad (12)$$

so

$$(\mathbf{I} - \lambda \mathbf{A}) \mathbf{C} = \mathbf{B} \quad (13)$$

$$\mathbf{C} = (\mathbf{I} - \lambda \mathbf{A})^{-1} \mathbf{B}. \quad (14)$$

see also FREDHOLM INTEGRAL EQUATION OF THE FIRST KIND, FREDHOLM INTEGRAL EQUATION OF THE SECOND KIND, VOLTERRA INTEGRAL EQUATION OF THE FIRST KIND, VOLTERRA INTEGRAL EQUATION OF THE SECOND KIND

#### Integral of Motion

A function of the coordinates which is constant along a trajectory in PHASE SPACE. The number of DEGREES OF FREEDOM of a DYNAMICAL SYSTEM such as the DUFFING DIFFERENTIAL EQUATION can be decreased by one if an integral of motion can be found. In general, it is very difficult to discover integrals of motion.

#### Integral Sign

The symbol  $\int$  used to denote an INTEGRAL  $\int f(x) dx$ . The symbol was chosen to be a stylized script "S" to stand for "summation."

see also INTEGRAL

#### Integral Test

Let  $\sum u_k$  be a series with POSITIVE terms and let  $f(x)$  be the function that results when  $k$  is replaced by  $x$  in the FORMULA for  $u_k$ . If  $f$  is decreasing and continuous for  $x \geq 1$  and

$$\lim_{x \rightarrow \infty} f(x) = 0,$$

then

$$\sum_{k=1}^{\infty} u_k$$

and

$$\int_1^{\infty} f(x) dx$$

both converge or diverge, where  $1 \leq t < \infty$ . The test is also called the CAUCHY INTEGRAL TEST or MACLAURIN INTEGRAL TEST.

#### Integrand

The quantity being INTEGRATED, also called the KERNEL. For example, in  $\int f(x) dx$ ,  $f(x)$  is the integrand.

see also INTEGRAL, INTEGRATION

**Integrating Factor**

A FUNCTION by which an ORDINARY DIFFERENTIAL EQUATION is multiplied in order to make it integrable.

see also ORDINARY DIFFERENTIAL EQUATION

References

Morse, P. M. and Feshbach, H. *Methods of Theoretical Physics, Part I*. New York: McGraw-Hill, pp. 526–529, 1953.

**Integration**

The process of computing or obtaining an INTEGRAL. A more archaic term for integration is QUADRATURE.

see also CONTOUR INTEGRATION, INTEGRAL, INTEGRATION BY PARTS, MEASURE THEORY, NUMERICAL INTEGRATION

**Integration Lattice**

A discrete subset of  $\mathbb{R}^s$  which is closed under addition and subtraction and which contains  $\mathbb{Z}^s$  as a SUBSET.

see also LATTICE

References

Sloan, I. H. and Joe, S. *Lattice Methods for Multiple Integration*. New York: Oxford University Press, 1994.

**Integration by Parts**

A first-order (single) integration by parts uses

$$d(uv) = u dv + v du \quad (1)$$

$$\int d(uv) = uv = \int u dv + \int v du, \quad (2)$$

so

$$\int u dv = uv - \int v du \quad (3)$$

and

$$\int_a^b u dv = [uv]_a^b - \int_{f(a)}^{f(b)} v du. \quad (4)$$

Now apply this procedure  $n$  times to  $\int f^{(n)}(x)g(x) dx$ .

$$u = g(x) \quad dv = f^{(n)}(x) dx \quad (5)$$

$$du = g'(x) dx \quad v = f^{(n-1)}(x). \quad (6)$$

Therefore,

$$\int f^{(n)}g(x) dx = g(x)f^{(n-1)}(x) - \int f^{(n-1)}(x)g'(x) dx. \quad (7)$$

But

$$\begin{aligned} & \int f^{(n-1)}(x)g'(x) dx \\ &= g'(x)f^{(n-2)}(x) - \int f^{(n-2)}(x)g''(x) dx \quad (8) \end{aligned}$$

$$\begin{aligned} & \int f^{(n-2)}(x)g''(x) dx \\ &= g''(x)f^{(n-3)}(x) - \int f^{(n-3)}(x)g^{(3)}(x) dx, \quad (9) \end{aligned}$$

so

$$\begin{aligned} & \int f^{(n)}(x)g(x) dx = g(x)f^{(n-1)}(x) - g'(x)f^{(n-2)}(x) \\ & + g''(x)f^{(n-3)}(x) - \dots + (-1)^n \int f(x)g^{(n)}(x) dx. \quad (10) \end{aligned}$$

Now consider this in the slightly different form  $\int f(x)g(x) dx$ . Integrate by parts a first time

$$u = f(x) \quad dv = g(x) dx \quad (11)$$

$$du = f'(x) dx \quad v = \int g(x) dx, \quad (12)$$

so

$$\begin{aligned} & \int f(x)g(x) dx = f(x) \int g(x) dx \\ & - \int \left[ \int g(x) dx \right] f'(x) dx. \quad (13) \end{aligned}$$

Now integrate by parts a second time,

$$u = f'(x) \quad dv = \int g(x)(dx)^2 \quad (14)$$

$$du = f''(x) dx \quad v = \iint g(x)(dx)^2, \quad (15)$$

so

$$\begin{aligned} & \int f(x)g(x) dx = f(x) \int g(x) dx - f'(x) \iint g(x)(dx)^2 \\ & + \int \left[ \iint g(x)(dx)^2 \right] f''(x) dx. \quad (16) \end{aligned}$$

Repeating a third time,

$$\begin{aligned} & \int f(x)g(x) dx = f(x) \int g(x) dx - f'(x) \iint g(x)(dx)^2 \\ & + f''(x) \iiint g(x)(dx)^3 \\ & - \int \left[ \iiint g(x)(dx)^3 \right] f'''(x) dx. \quad (17) \end{aligned}$$

Therefore, after  $n$  applications,

$$\begin{aligned} \int f(x)g(x) dx &= f(x) \int g(x) dx - f'(x) \iint g(x)(dx)^2 \\ &\quad + f''(x) \iiint g(x)(dx)^3 - \dots \\ &\quad + (-1)^{n+1} f^{(n)}(x) \underbrace{\int \dots \int g(x)(dx)^{n+1}}_{n+1} \\ &\quad + (-1)^n \int \left[ \underbrace{\int \dots \int g(x)(dx)^{n+1}}_{n+1} \right] f^{(n+1)}(x) dx. \quad (18) \end{aligned}$$

If  $f^{(n+1)}(x) = 0$  (e.g., for an  $n$ th degree POLYNOMIAL), the last term is 0, so the sum terminates after  $n$  terms and

$$\begin{aligned} \int f(x)g(x) dx &= f(x) \int g(x) dx \\ &\quad - f'(x) \iint g(x)(dx)^2 + f''(x) \iiint g(x)(dx)^3 - \dots \\ &\quad + (-1)^{n+1} f^{(n)}(x) \underbrace{\int \dots \int g(x)(dx)^{n+1}}_{n+1}. \quad (19) \end{aligned}$$

P.; Teukolsky, S. A.; and Vetterling, W. T. "Interpolation and Extrapolation." Ch. 3 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 99-122, 1992.

**Interquartile Range**

Divide a set of data into two groups (high and low) of equal size at the MEDIAN if there is an EVEN number of data points, or two groups consisting of points on either side of the MEDIAN itself plus the MEDIAN if there is an ODD number of data points. Find the MEDIANS of the low and high groups, denoting these first and third quartiles by  $Q_1$  and  $Q_3$ . The interquartile range is then defined by

$$\text{IQR} \equiv Q_3 - Q_1.$$

see also *H-SPREAD*, *HINGE*, *MEDIAN* (STATISTICS)

**Interradius**

see *MIDRADIUS*

**Intersection**

The intersection of two sets  $A$  and  $B$  is the set of elements common to  $A$  and  $B$ . This is written  $A \cap B$ , and is pronounced “ $A$  intersection  $B$ ” or “ $A$  cap  $B$ .” The intersection of sets  $A_1$  through  $A_n$  is written  $\bigcap_{i=1}^n A_i$ . The intersection of lines  $AB$  and  $CD$  is written  $AB \cap CD$ .

see also *AND*, *UNION*

**Interspersion**

An ARRAY  $A = a_{ij}$ ,  $i, j \geq 1$  of POSITIVE INTEGERS is called an interspersion if

1. The rows of  $A$  comprise a PARTITION of the POSITIVE INTEGERS,
2. Every row of  $A$  is an increasing sequence,
3. Every column of  $A$  is a (possibly FINITE) increasing sequence,
4. If  $(u_j)$  and  $(v_j)$  are distinct rows of  $A$  and if  $p$  and  $q$  are any indices for which  $u_p < v_q < u_{p+1}$ , then  $u_{p+1} < v_{q+1} < u_{p+2}$ .

If an array  $A = a_{ij}$  is an interspersion, then it is a DISPERSION. If an array  $A = a(i, j)$  is an interspersion, then the sequence  $\{x_n\}$  given by  $\{x_n = i : n = (i, j)\}$  for some  $j$  is a FRACTAL SEQUENCE. Examples of interspersion are the STOLARSKY ARRAY and WYTHOFF ARRAY.

see also *DISPERSION* (SEQUENCE), *FRACTAL SEQUENCE*, *STOLARSKY ARRAY*

**Intersphere**

see *MIDSPHERE*

**Interval**

A collection of points on a LINE SEGMENT. If the endpoints  $a$  and  $b$  are FINITE and are included, the interval is called CLOSED and is denoted  $[a, b]$ . If one of the endpoints is  $\pm\infty$ , then the interval still contains all of its LIMIT POINTS, so  $[a, \infty)$  and  $(-\infty, b]$  are also closed intervals. If the endpoints are not included, the interval is called OPEN and denoted  $(a, b)$ . If one endpoint is included but not the other, the interval is denoted  $[a, b)$  or  $(a, b]$  and is called a HALF-CLOSED (or HALF-OPEN) interval.

see also *CLOSED INTERVAL*, *HALF-CLOSED INTERVAL*, *LIMIT POINT*, *OPEN INTERVAL*, *PENCIL*

**Interval Graph**

A GRAPH  $G = (V, E)$  is an interval graph if it captures the INTERSECTION RELATION for some set of INTERVALS on the REAL LINE. Formally,  $P$  is an interval graph provided that one can assign to each  $v \in V$  an interval  $I_v$  such that  $I_u \cap I_v$  is nonempty precisely when  $uv \in E$ .

see also *COMPARABILITY GRAPH*

**Interval Order**

A POSET  $P = (X, \leq)$  is an interval order if it is ISOMORPHIC to some set of INTERVALS on the REAL LINE ordered by left-to-right precedence. Formally,  $P$  is an interval order provided that one can assign to each  $x \in X$  an INTERVAL  $[x_L, x_R]$  such that  $x_R < y_L$  in the REAL NUMBERS IFF  $x < y$  in  $P$ .

**Intrinsic Curvature**

A CURVATURE such as GAUSSIAN CURVATURE which is detectable to the “inhabitants” of a surface and not just outside observers. An EXTRINSIC CURVATURE, on the other hand, is not detectable to someone who can’t study the 3-dimensional space surrounding the surface on which he resides.

see also *CURVATURE*, *EXTRINSIC CURVATURE*, *GAUSSIAN CURVATURE*

### Intrinsic Equation

An equation which specifies a CURVE in terms of intrinsic properties such as ARC LENGTH, RADIUS OF CURVATURE, and TANGENTIAL ANGLE instead of with reference to artificial coordinate axes. Intrinsic equations are also called NATURAL EQUATIONS.

see also CESÀRO EQUATION, NATURAL EQUATION, WHEWELL EQUATION

#### References

### Invariant

A quantity which remains unchanged under certain classes of transformations. Invariants are extremely useful for classifying mathematical objects because they usually reflect intrinsic properties of the object of study.

see ADIABATIC INVARIANT, ALEXANDER INVARIANT, ALGEBRAIC INVARIANT, ARF INVARIANT, INTEGRAL OF MOTION

#### References

Hunt, B. "Invariants." Appendix B.1 in *The Geometry of Some Special Arithmetic Quotients*. New York: Springer-Verlag, pp. 282–290, 1996.

### Invariant Density

see NATURAL INVARIANT

### Invariant (Elliptic Function)

The invariants of a WEIERSTRASS ELLIPTIC FUNCTION are defined by

$$g_2 \equiv 60\Sigma'\Omega_{mn}^{-4}$$

$$g_3 \equiv 140\Sigma'\Omega_{mn}^{-6}.$$

Here,

$$\Omega_{mn} \equiv 2m\omega_1 - 2n\omega_2,$$

where  $\omega_1$  and  $\omega_2$  are the periods of the ELLIPTIC FUNCTION.

### Invariant Manifold

When stable and unstable invariant MANIFOLDS intersect, they do so in a HYPERBOLIC FIXED POINT (SADDLE POINT). The invariant MANIFOLDS are then called SEPARATRICES. A HYPERBOLIC FIXED POINT is characterized by two ingoing stable MANIFOLDS and two outgoing unstable MANIFOLDS. In integrable systems, incoming  $W^s$  and outgoing  $W^u$  MANIFOLDS all join up smoothly.

A stable invariant MANIFOLD  $W^s$  of a FIXED POINT  $Y^*$  is the set of all points  $Y_0$  such that the trajectory passing through  $Y_0$  tends to  $Y^*$  as  $j \rightarrow \infty$ .

An unstable invariant MANIFOLD  $W^u$  of a FIXED POINT  $Y^*$  is the set of all points  $Y_0$  such that the trajectory passing through  $Y_0$  tends to  $Y^*$  as  $j \rightarrow -\infty$ .

see also HOMOCLINIC POINT

### Invariant Point

### Invariant Subgroup

see NORMAL SUBGROUP

### Inverse Cosecant

The function  $\csc^{-1} x$ , also denoted  $\operatorname{arccsc}(x)$ , where  $\csc x$  is the COSECANT and the SUPERScript  $-1$  denotes an

INVERSE FUNCTION, *not* the multiplicative inverse. The inverse cosecant satisfies

$$\csc^{-1} x = \sec^{-1} \left( \frac{x}{\sqrt{x^2 - 1}} \right) \quad (1)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\csc^{-1} x = \pi + \csc^{-1}(-x) \quad (2)$$

for  $x \geq 0$ . The inverse cosecant is given in terms of other inverse trigonometric functions by

$$\csc^{-1} = \cos^{-1} \left( \frac{\sqrt{x^2 - 1}}{x} \right) \quad (3)$$

$$= \cot^{-1}(\sqrt{x^2 - 1}) \quad (4)$$

$$= \frac{1}{2}\pi - \sec^{-1} x = -\frac{1}{2}\pi - \sec^{-1}(-x) \quad (5)$$

$$= \sin^{-1} \left( \frac{1}{x} \right) \quad (6)$$

for  $x \geq 0$ .

see also COSECANT INVERSE SINE, SINE

### Inverse Cosine

The function  $\cos^{-1} x$ , also denoted  $\arccos(x)$ , where  $\cos x$  is the COSINE and the superscript  $-1$  denotes an INVERSE FUNCTION, *not* the multiplicative inverse. The MACLAURIN SERIES for the inverse cosine range  $-1 < x < 1$  is

$$\cos^{-1} x = \frac{1}{2}\pi - x - \frac{1}{6}x^3 - \frac{3}{40}x^5 - \frac{5x}{112}x^7 - \frac{35}{1152}x^9 - \dots \quad (1)$$

The inverse cosine satisfies

$$\cos^{-1} x = \pi - \cos^{-1}(-x) \quad (2)$$

for POSITIVE and NEGATIVE  $x$ , and

$$\cos^{-1} = \frac{1}{2}\pi - \cos^{-1}(\sqrt{1 - x^2}) \quad (3)$$

for  $x \geq 0$ . The inverse cosine is given in terms of other inverse trigonometric functions by

$$\cos^{-1} x = \cot^{-1} \left( \frac{x}{\sqrt{1 - x^2}} \right) \quad (4)$$

$$= \frac{1}{2}\pi + \sin^{-1}(-x) = \frac{1}{2}\pi - \sin^{-1} x \quad (5)$$

$$= \frac{1}{2}\pi - \tan^{-1} \left( \frac{x}{\sqrt{1 - x^2}} \right) \quad (6)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\cos^{-1} x = \csc^{-1} \left( \frac{1}{\sqrt{1 - x^2}} \right) \quad (7)$$

$$= \sec^{-1} \left( \frac{1}{x} \right) \quad (8)$$

$$= \sin^{-1}(\sqrt{1 - x^2}) \quad (9)$$

$$= \tan^{-1} \left( \frac{\sqrt{1 - x^2}}{x} \right) \quad (10)$$

for  $x \geq 0$ .

### Inverse Cotangent

The function  $\cot^{-1} x$ , also denoted  $\text{arccot}(x)$ , where  $\cot x$  is the COTANGENT and the superscript  $-1$  denotes an INVERSE FUNCTION and *not* the multiplicative inverse. The MACLAURIN SERIES is given by

$$\cot^{-1} x = \frac{1}{2}\pi - x + \frac{1}{3}x^3 - \frac{1}{5}x^5 + \frac{1}{7}x^7 - \frac{1}{9}x^9 + \dots, \quad (1)$$

and POWER SERIES by

$$\cot^{-1} x = x^{-1} - \frac{1}{3}x^{-3} + \frac{1}{5}x^{-5} - \frac{1}{7}x^{-7} + \frac{1}{9}x^{-9} + \dots \quad (2)$$

Euler derived the INFINITE series

$$\cot^{-1} x = x \left[ \frac{1}{x^2 + 1} + \frac{2}{3(x^2 + 1)^2} + \frac{2 \cdot 4}{3 \cdot 5(x^2 + 1)^3} + \dots \right] \quad (3)$$

(Wetherfield 1996).

The inverse cotangent satisfies

$$\cot^{-1} x = \pi - \cot^{-1}(-x) \quad (4)$$

for POSITIVE and NEGATIVE  $x$ , and

$$\cot^{-1} = \frac{1}{2}\pi - \cot^{-1}\left(\frac{1}{x}\right) \quad (5)$$

for  $x \geq 0$ . The inverse cotangent is given in terms of other inverse trigonometric functions by

$$\cot^{-1} x = \cos^{-1}\left(\frac{x}{\sqrt{x^2 + 1}}\right) \quad (6)$$

$$= \frac{1}{2}\pi - \sin^{-1}\left(\frac{x}{\sqrt{x^2 + 1}}\right) \quad (7)$$

$$= \frac{1}{2}\pi + \tan^{-1}(-x) = \frac{1}{2}\pi - \tan^{-1} x \quad (8)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\cot^{-1} x = \csc^{-1}(\sqrt{x^2 + 1}) \quad (9)$$

$$= \sec^{-1}\left(\frac{\sqrt{x^2 + 1}}{x}\right) \quad (10)$$

$$= \sin^{-1}\left(\frac{1}{\sqrt{x^2 + 1}}\right) \quad (11)$$

$$= \tan^{-1}\left(\frac{1}{x}\right) \quad (12)$$

for  $x \geq 0$ .

A number

$$t_x = \cot^{-1} x, \quad (13)$$

where  $x$  is an INTEGER or RATIONAL NUMBER, is sometimes called a GREGORY NUMBER. Lehmer (1938a) showed that  $\cot^{-1}(a/b)$  can be expressed as a finite sum of inverse cotangents of INTEGER arguments

$$\cot^{-1}\left(\frac{a}{b}\right) = \sum_{i=1}^k (-1)^{i-1} \cot^{-1} n_i, \quad (14)$$

where

$$n_i = \left\lfloor \frac{a_i}{b_i} \right\rfloor, \quad (15)$$

with  $\lfloor x \rfloor$  the FLOOR FUNCTION, and

$$a_{i+1} = a_i n_i + i + b_i \quad (16)$$

$$b_{i+1} = a_i - n_i b_i, \quad (17)$$

with  $a_0 = a$  and  $b_0 = b$ , and where the recurrence is continued until  $b_{k+1} = 0$ . If an INVERSE TANGENT sum is written as

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k + f \tan^{-1}, \quad (18)$$

then equation (14) becomes

$$\cot^{-1} n = \sum_{k=1} f_k \cot^{-1} n_k + c \cot^{-1} 1, \quad (19)$$

where

$$c = 2 - f - 2 \sum_{k=1} f_k. \quad (20)$$

Inverse cotangent sums can be used to generate MACHIN-LIKE FORMULAS.

An interesting inverse cotangent identity attributed to Charles Dodgson (Lewis Carroll) by Lehmer (1938b; Bromwich 1965; Castellanos 1988ab) is

$$\cot^{-1}(p+r) + \tan^{-1}(p+q) = \tan^{-1} p, \quad (21)$$

where

$$1 + p^2 = qr. \quad (22)$$

Other inverse cotangent identities include

$$2 \cot^{-1}(2x) - \cot^{-1} x = \cot^{-1}(4x^3 + 3x) \quad (23)$$

$$3 \cot^{-1}(3x) - \cot^{-1} x = \cot^{-1}\left(\frac{27x^4 + 18x^2 - 1}{8x}\right), \quad (24)$$

as well as many others (Bennett 1926, Lehmer 1938b). see also COTANGENT, INVERSE TANGENT, MACHIN'S FORMULA, MACHIN-LIKE FORMULAS, TANGENT

**Inverse Curve**

Given a CIRCLE  $C$  with CENTER  $O$  and RADIUS  $k$ , then two points  $P$  and  $Q$  are inverse with respect to  $C$  if  $OP \cdot OQ = k^2$ . If  $P$  describes a curve  $C_1$ , then  $Q$  describes a curve  $C_2$  called the inverse of  $C_1$  with respect to the circle  $C$  (with INVERSION CENTER  $O$ ). If the POLAR equation of  $C$  is  $r(\theta)$ , then the inverse curve has polar equation

$$r = \frac{k^2}{r(\theta)}.$$

If  $O = (x_0, y_0)$  and  $P = (f(t), g(t))$ , then the inverse has equations

$$x = x_0 + \frac{k^2(f - x_0)}{(f - x_0)^2 + (g - y_0)^2}$$

$$y = y_0 + \frac{k^2(g - y_0)}{(f - x_0)^2 + (g - y_0)^2}.$$

**Inverse Secant**

The function  $\sec^{-1} x$ , where  $\sec x$  is the SECANT and the superscript  $-1$  denotes the INVERSE FUNCTION, *not* the multiplicative inverse. The inverse secant satisfies

$$\sec^{-1} x = \csc^{-1} \left( \frac{x}{\sqrt{x^2 - 1}} \right) \quad (1)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\sec^{-1} x = \pi + \sec^{-1}(-x) \quad (2)$$

for  $x \geq 0$ . The inverse secant is given in terms of other inverse trigonometric functions by

$$\sec^{-1} x = \cos^{-1} \left( \frac{1}{x} \right) \quad (3)$$

$$= \cot^{-1} \left( \frac{1}{\sqrt{x^2 - 1}} \right) \quad (4)$$

$$= \frac{1}{2}\pi - \csc^{-1} x = -\frac{1}{2}\pi + \csc^{-1}(-x) \quad (5)$$

$$= \sin^{-1} \left( \frac{\sqrt{x^2 - 1}}{x} \right) \quad (6)$$

$$= \tan^{-1}(\sqrt{x^2 - 1}) \quad (7)$$

for  $x \geq 0$ .

**Inverse Sine**

The function  $\sin^{-1} x$ , where  $\sin x$  is the SINE and the superscript  $-1$  denotes the INVERSE FUNCTION, *not* the multiplicative inverse. The inverse sine satisfies

$$\sin^{-1} x = -\sin^{-1}(-x) \quad (1)$$

for POSITIVE and NEGATIVE  $x$ , and

$$\sin^{-1} = \frac{1}{2}\pi - \sin^{-1}(\sqrt{1 - x^2}) \quad (2)$$

for  $x \geq 0$ . The inverse sine is given in terms of other inverse trigonometric functions by

$$\sin^{-1} x = \cos^{-1}(-x) - \frac{1}{2}\pi = \frac{1}{2}\pi - \cos^{-1} x \quad (3)$$

$$= \frac{1}{2}\pi - \cot^{-1} \left( \frac{x}{\sqrt{1-x^2}} \right) \quad (4)$$

$$= \tan^{-1} \left( \frac{x}{\sqrt{1-x^2}} \right) \quad (5)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\sin^{-1} x = \cos^{-1}(\sqrt{1-x^2}) \quad (6)$$

$$= \cot^{-1} \left( \frac{\sqrt{1-x^2}}{x} \right) \quad (7)$$

$$= \csc^{-1} \left( \frac{1}{x} \right) \quad (8)$$

$$= \sec^{-1} \left( \frac{1}{\sqrt{1-x^2}} \right) \quad (9)$$

for  $x \geq 0$ .

#### Inverse Tangent

The inverse tangent is also called the arctangent and is denoted either  $\tan^{-1} x$  or  $\arctan x$ . It has the MACLAURIN SERIES

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{(-1)^n x^{2n+1}}{2n+1} = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \dots \quad (1)$$

A more rapidly converging form due to Euler is given by

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{2^{2n} (n!)^2}{(2n+1)!} \frac{x^{2n+1}}{(1+x^2)^{n+1}} \quad (2)$$

(Castellanos 1988). The inverse tangent satisfies

$$\tan^{-1} x = -\tan^{-1}(-x) \quad (3)$$

for POSITIVE and NEGATIVE  $x$ , and

$$\tan^{-1} = \frac{1}{2}\pi - \tan^{-1} \left( \frac{1}{x} \right) \quad (4)$$

for  $x \geq 0$ . The inverse tangent is given in terms of other inverse trigonometric functions by

$$\tan^{-1} x = \frac{1}{2}\pi - \cos^{-1} \left( \frac{x}{\sqrt{x^2+1}} \right) \quad (5)$$

$$= \cot^{-1}(-x) - \frac{1}{2}\pi = \frac{1}{2}\pi - \cot^{-1} x \quad (6)$$

$$= \sin^{-1} \left( \frac{x}{\sqrt{x^2+1}} \right) \quad (7)$$

for POSITIVE or NEGATIVE  $x$ , and

$$\tan^{-1} x = \cos^{-1} \left( \frac{1}{\sqrt{x^2+1}} \right) \quad (8)$$

$$= \cot^{-1} \left( \frac{1}{x} \right) \quad (9)$$

$$= \csc^{-1} \left( \frac{\sqrt{x^2+1}}{x} \right) \quad (10)$$

$$= \sec^{-1}(\sqrt{x^2+1}) \quad (11)$$

for  $x \geq 0$ .

In terms of the HYPERGEOMETRIC FUNCTION,

$$\tan^{-1} x = x {}_2F_1\left(1, \frac{1}{2}; \frac{3}{2}; -x^2\right) \quad (12)$$

$$= \frac{x}{1+x^2} {}_2F_1\left(1, 1; \frac{3}{2}; \frac{x^2}{1+x^2}\right) \quad (13)$$

(Castellanos 1988). Castellanos (1986, 1988) also gives some curious formulas in terms of the FIBONACCI NUMBERS,

$$\tan^{-1} x = \sum_{n=0}^{\infty} \frac{(-1)^n F_{2n+1} t^{2n+1}}{5^n (2n+1)} \quad (14)$$

$$= 5 \sum_{n=0}^{\infty} \frac{(-1)^n F_{2n+1}^2}{(2n+1)(u + \sqrt{u^2+1})^{2n+1}} \quad (15)$$

$$= \sum_{n=0}^{\infty} \frac{(-1)^n 5^{n+2} F_{2n+1}^3}{(2n+1)(v + \sqrt{v^2+5})^{2n+1}}, \quad (16)$$

where

$$t \equiv \frac{2x}{1 + \sqrt{\frac{4x^2}{5}}} \quad (17)$$

$$u \equiv \frac{5}{4x} \left( 1 + \sqrt{1 + \frac{24}{25}x^2} \right), \quad (18)$$

and  $v$  is the largest POSITIVE ROOT of

$$8xv^4 - 100v^3 - 450xv^2 + 875v + 625x = 0. \quad (19)$$

The inverse tangent satisfies the addition FORMULA

$$\tan^{-1} x + \tan^{-1} y = \tan^{-1} \left( \frac{x+y}{1-xy} \right) \quad (20)$$

as well as the more complicated FORMULAS

$$\tan^{-1} \left( \frac{1}{a-b} \right) = \tan^{-1} \left( \frac{1}{a} \right) + \tan^{-1} \left( \frac{b}{a^2 - ab + 1} \right) \quad (21)$$

$$\tan^{-1} \left( \frac{1}{a} \right) = 2 \tan^{-1} \left( \frac{1}{2a} \right) - \tan^{-1} \left( \frac{1}{4a^3 + 3a} \right) \quad (22)$$

$$\tan^{-1} \left( \frac{1}{p} \right) = \tan^{-1} \left( \frac{1}{p+q} \right) + \tan^{-1} \left( \frac{q}{p^2 + pq + 1} \right), \quad (23)$$

the latter of which was known to Euler. The inverse tangent FORMULAS are connected with many interesting approximations to  $\pi$

$$\tan^{-1}(1+x) = \frac{1}{4}\pi + \frac{1}{2}x - \frac{1}{4}x^2 + \frac{1}{12}x^3 + \frac{1}{40}x^5 + \frac{1}{48}x^6 + \frac{1}{112}x^7 + \dots \quad (24)$$

Euler gave

$$\tan^{-1} x = \frac{y}{x} \left( \frac{2}{3}y + \frac{2 \cdot 4}{3 \cdot 5}y^2 + \frac{2 \cdot 4 \cdot 6}{3 \cdot 5 \cdot 7}y^3 + \dots \right), \quad (25)$$

where

$$y \equiv \frac{x^2}{1+x^2}. \quad (26)$$

The inverse tangent has CONTINUED FRACTION representations

$$\tan^{-1} x = \frac{x}{1 + \frac{x^2}{3 + \frac{4x^2}{5 + \frac{5x^2}{7 + \frac{16x^2}{9 + \dots}}}}} \quad (27)$$

$$= \frac{x}{1 + \frac{x^2}{3 - x^2 + \frac{9x^2}{5 - 3x^2 + \frac{25x^2}{7 - 5x^2 + \dots}}}}. \quad (28)$$

To find  $\tan^{-1} x$  numerically, the following ARITHMETIC-GEOMETRIC MEAN-like ALGORITHM can be used. Let

$$a_0 = (1+x^2)^{-1/2} \quad (29)$$

$$b_0 = 1. \quad (30)$$

Then compute

$$a_{i+1} = \frac{1}{2}(a_i + b_i) \quad (31)$$

$$b_{i+1} = \sqrt{a_{i+1}b_i}, \quad (32)$$

and the inverse tangent is given by

$$\tan^{-1} x = \lim_{n \rightarrow \infty} \frac{x}{\sqrt{1+x^2} a_n} \quad (33)$$

(Acton 1990).

An inverse tangent  $\tan^{-1} n$  with integral  $n$  is called reducible if it is expressible as a finite sum of the form

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k, \quad (34)$$

where  $f_k$  are POSITIVE or NEGATIVE INTEGERS and  $n_i$  are iNTEGERS  $< n$ .  $\tan^{-1} m$  is reducible IFF all the PRIME factors of  $1+m^2$  occur among the PRIME factors of  $1+n^2$  for  $n = 1, \dots, m-1$ . A second NECESSARY and SUFFICIENT condition is that the largest PRIME factor of  $1+m^2$  is less than  $2m$ . Equivalent to the second condition is the statement that every GREGORY NUMBER  $t_x = \cot^{-1} x$  can be uniquely expressed as a sum in terms of  $t_m$ s for which  $m$  is a STØRMER NUMBER (Conway and Guy 1996). To find this decomposition, write

$$\arg(1+in) = \arg \prod_{k=1} (1+n_k i)^{f_k}, \quad (35)$$

so the ratio

$$r = \frac{\prod_{k=1} (1+n_k i)^{f_k}}{1+in} \quad (36)$$

is a RATIONAL NUMBER. Equation (36) can also be written

$$r^2(1+n^2) = \prod_{k=1} (1+n_k^2)^{f_k}. \quad (37)$$

Writing (34) in the form

$$\tan^{-1} n = \sum_{k=1} f_k \tan^{-1} n_k + f \tan^{-1} 1 \quad (38)$$

allows a direct conversion to a corresponding INVERSE COTANGENT FORMULA

$$\cot^{-1} n = \sum_{k=1} f_k \cot^{-1} n_k + c \cot^{-1} 1, \quad (39)$$

where

$$c = 2 - f - 2 \sum_{k=1} f_r. \quad (40)$$

Todd (1949) gives a table of decompositions of  $\tan^{-1} n$  for  $n \leq 342$ . Conway and Guy (1996) give a similar table in terms of STØRMER NUMBERS.

Arndt and Gosper give the remarkable inverse tangent identity

$$\sin \left( \sum_{k=1}^{2n+1} \tan^{-1} a_k \right) = \frac{(-1)^n \sum_{k=1}^{2n+1} \prod_{j=1}^{2n+1} [a_j - \tan(\frac{\pi(j-k)}{2n+1})]}{2n+1 \sqrt{\prod_{j=1}^{2n+1} (a_j^2 + 1)}}. \quad (41)$$

see also INVERSE COTANGENT, TANGENT

### Inversely Similar

inversely similar

Two figures are said to be SIMILAR when all corresponding ANGLES are equal, and are inversely similar when all corresponding ANGLES are equal and described in the opposite rotational sense.

see also DIRECTLY SIMILAR, SIMILAR

### Inversion

Inversion is the process of transforming points to their INVERSE POINTS. This sort of inversion was first systematically investigated by Jakob Steiner. Two points are said to be inverses with respect to an INVERSION CIRCLE with INVERSION CENTER  $O = (x_0, y_0)$  and INVERSION RADIUS  $k$  if  $PT$  and  $PS$  are line segments symmetric about  $OP$  and tangent to the CIRCLE, and  $Q$  is the intersection of  $OP$  and  $ST$ . The curve to which a given curve is transformed under inversion is called its INVERSE CURVE.

Note that a point on the CIRCUMFERENCE of the INVERSION CIRCLE is its own inverse point. The inverse points obey

$$\frac{OP}{k} = \frac{k}{OQ}, \quad (1)$$

or

$$k^2 = OP \times OQ, \quad (2)$$

where  $k^2$  is called the POWER. The equation for the inverse of the point  $(x, y)$  relative to the INVERSION CIRCLE with INVERSION CENTER  $(x_0, y_0)$  and inversion radius  $k$  is therefore

$$x' = x_0 + \frac{k^2(x - x_0)}{(x - x_0)^2 + (y - y_0)^2} \quad (3)$$

$$y' = y_0 + \frac{k^2(y - y_0)}{(x - x_0)^2 + (y - y_0)^2}. \quad (4)$$

In vector form,

$$\mathbf{x}' = \mathbf{x}_0 + \frac{k^2(\mathbf{x} - \mathbf{x}_0)}{|\mathbf{x} - \mathbf{x}_0|^2}. \quad (5)$$

Any ANGLE inverts to an opposite ANGLE.

Treating LINES as CIRCLES of INFINITE RADIUS, all CIRCLES invert to CIRCLES. Furthermore, any two nonintersecting circles can be inverted into concentric circles by taking the INVERSION CENTER at one of the two limiting points (Coxeter 1969), and ORTHOGONAL CIRCLES invert to ORTHOGONAL CIRCLES (Coxeter 1969).

The inverse of a CIRCLE of RADIUS  $a$  with CENTER  $(x, y)$  with respect to an inversion circle with INVERSION CENTER  $(0, 0)$  and INVERSION RADIUS  $k$  is another CIRCLE with CENTER  $(x', y') = (sx, sy)$  and RADIUS  $r' = |s|a$ , where

$$s \equiv \frac{k^2}{x^2 + y^2 - a^2}. \quad (6)$$

The above plot shows a checkerboard centered at  $(0, 0)$  and its inverse about a small circle also centered at  $(0, 0)$  (Dixon 1991).

#### Inversion Center

The point that INVERSION OF A CURVE is performed with respect to.

see also INVERSE POINTS, INVERSION CIRCLE, INVERSION RADIUS, INVERSIVE DISTANCE, POLAR, POLE (GEOMETRY), POWER (CIRCLE)

#### Inversion Circle

The CIRCLE with respect to which a INVERSE CURVE is computed or relative to which INVERSE POINTS are computed.

see also INVERSE POINTS, INVERSION CENTER, INVERSION RADIUS, INVERSIVE DISTANCE, MIDCIRCLE, POLAR, POLE (GEOMETRY), POWER (CIRCLE)

#### Inversion Operation

The SYMMETRY OPERATION  $(x, y, z) \rightarrow (-x, -y, -z)$ . When used in conjunction with a ROTATION, it becomes an IMPROPER ROTATION.

#### Inversion Radius

The RADIUS used in performing an INVERSION with respect to an INVERSION CIRCLE.

see also INVERSE POINTS, INVERSION CENTER, INVERSION CIRCLE, INVERSIVE DISTANCE, POLAR, POLE (GEOMETRY), POWER (CIRCLE)

#### Inversive Distance

The inversive distance is the NATURAL LOGARITHM of the ratio of two concentric circles into which the given circles can be inverted. Let  $c$  be the distance between the centers of two nonintersecting CIRCLES of RADIUS  $a$  and  $b < a$ . Then the inversive distance is

$$\delta = \cosh^{-1} \left| \frac{a^2 + b^2 - c^2}{2ab} \right|$$

(Coxeter and Greitzer 1967).

The inversive distance between the SODDY CIRCLES is given by

$$\delta = 2 \cosh^{-1} 2,$$

and the CIRCUMCIRCLE and INCIRCLE of a TRIANGLE with CIRCUMRADIUS  $R$  and INRADIUS  $r$  are at inversive distance

$$\delta = 2 \sinh^{-1} \left( \frac{1}{2} \sqrt{\frac{r}{R}} \right)$$

(Coxeter and Greitzer 1967, pp. 130–131).

### Involuntary

A LINEAR TRANSFORMATION of period two. Since a LINEAR TRANSFORMATION has the form,

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda + \delta}, \quad (1)$$

applying the transformation a second time gives

$$\lambda'' = \frac{\alpha\lambda' + \beta}{\gamma\lambda' + \delta} = \frac{(\alpha^2 + \beta\gamma)\lambda + \beta(\alpha + \delta)}{(\alpha + \delta)\gamma\lambda + \beta\gamma + \delta^2}. \quad (2)$$

For an involuntary,  $\lambda'' = \lambda$ , so

$$\gamma(\alpha + \delta)\lambda^2 + (\delta^2 - \alpha^2)\lambda - (\alpha + \delta)\beta = 0. \quad (3)$$

Since each COEFFICIENT must vanish separately,

$$\alpha\gamma + \gamma\delta = 0 \quad (4)$$

$$\delta^2 - \alpha^2 = 0 \quad (5)$$

$$\alpha\beta + \beta\delta = 0. \quad (6)$$

The first equation gives  $\delta = \pm\alpha$ . Taking  $\delta = \alpha$  would require  $\gamma = \beta = 0$ , giving  $\lambda = \lambda'$ , the identity transformation. Taking  $\delta = -\alpha$  gives  $\delta = -\alpha$ , so

$$\lambda' = \frac{\alpha\lambda + \beta}{\gamma\lambda - \alpha}, \quad (7)$$

the general form of an INVOLUTION.

### Involute

Attach a string to a point on a curve. Extend the string so that it is tangent to the curve at the point of attachment. Then wind the string up, keeping it always taut. The LOCUS of points traced out by the end of the string is the involute of the original curve, and the original curve is called the EVOLUTE of its involute. Although a curve has a unique EVOLUTE, it has infinitely many involutes corresponding to different choices of initial point. An involute can also be thought of as any

curve ORTHOGONAL to all the TANGENTS to a given curve.

The equation of the involute is

$$\mathbf{r}_i = \mathbf{r} - s\hat{\mathbf{T}}, \quad (1)$$

where  $\hat{\mathbf{T}}$  is the TANGENT VECTOR

$$\hat{\mathbf{T}} = \frac{\frac{d\mathbf{r}}{dt}}{\left| \frac{d\mathbf{r}}{dt} \right|} \quad (2)$$

and  $s$  is the ARC LENGTH

$$s = \int ds = \int \frac{ds}{dt} dt = \int \frac{\sqrt{ds^2}}{dt} dt = \int \sqrt{f'^2 + g'^2} dt. \quad (3)$$

This can be written for a parametrically represented function  $(f(t), g(t))$  as

$$x(t) = f - \frac{sf'}{\sqrt{f'^2 + g'^2}} \quad (4)$$

$$y(t) = g - \frac{sg'}{\sqrt{f'^2 + g'^2}}. \quad (5)$$

Curve	Involute
astroid	astroid 1/2 as large
cardioid	cardioid 3 times as large
catenary	tractrix
circle catacaustic for a point source	limaçon
circle	circle involute (a spiral)
cycloid	equal cycloid
deltoid	deltoid 1/3 as large
ellipse	ellipse involute
epicycloid	reduced epicycloid
hypocycloid	similar hypocycloid
logarithmic spiral	equal logarithmic spiral
Neile's parabola	parabola
nephroid	Cayley's sextic
nephroid	nephroid 2 times as large

#### Involution (Group)

An element of order 2 in a GROUP (i.e., an element  $A$  of a GROUP such that  $A^2 = I$ , where  $I$  is the IDENTITY ELEMENT).

see also GROUP, IDENTITY ELEMENT

#### Involution (Line)

Pairs of points of a line, the product of whose distances from a FIXED POINT is a given constant. This is more concisely defined as a PROJECTIVITY of period two.

see also INVOLUNTARY

#### Involution (Operator)

An OPERATOR of period 2, i.e., an OPERATOR  $*$  which satisfies  $((a)*)^* = a$ .

#### Involution (Set)

An involution of a SET  $S$  is a PERMUTATION of  $S$  which does not contain any cycles of length  $> 2$ . The PERMUTATION MATRICES of an involution are SYMMETRIC. The number of involutions  $I(n)$  of a SET containing the first  $n$  integers is given by the RECURRENCE RELATION

$$I(n) = I(n-1) + (n-1)I(n-2).$$

For  $n = 1, 2, \dots$ , the first few values of  $I(n)$  are 1, 2, 4, 10, 26, 76, ... (Sloane's A000085). The number of involutions on  $n$  symbols cannot be expressed as a fixed number of hypergeometric terms (Petkovšek *et al.* 1996, p. 160).

see also PERMUTATION

### Irrational Number

A number which cannot be expressed as a FRACTION  $p/q$  for any INTEGERS  $p$  and  $q$ . Every TRANSCENDENTAL NUMBER is irrational. Numbers of the form  $n^{1/m}$  are irrational unless  $n$  is the  $m$ th POWER of an INTEGER.

Numbers of the form  $\log_n m$ , where  $\log$  is the LOGARITHM, are irrational if  $m$  and  $n$  are INTEGERS, one of which has a PRIME factor which the other lacks.  $e^r$  is irrational for rational  $r \neq 0$ . The irrationality of  $e$  was proven by Lambert in 1761; for the general case, see Hardy and Wright (1979, p. 46).  $\pi^n$  is irrational for POSITIVE integral  $n$ . The irrationality of  $\pi$  was proven by Lambert in 1760; for the general case, see Hardy and Wright (1979, p. 47). APÉRY'S CONSTANT  $\zeta(3)$  (where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION) was proved irrational by Apéry (Apéry 1979, van der Poorten 1979).

From GELFOND'S THEOREM, a number of the form  $a^b$  is TRANSCENDENTAL (and therefore irrational) if  $a$  is ALGEBRAIC  $\neq 0, 1$  and  $b$  is irrational and ALGEBRAIC. This establishes the irrationality of  $e^\pi$  (since  $(-1)^{-i} = (e^{i\pi})^{-i} = e^\pi$ ),  $2^{\sqrt{2}}$ , and  $e\pi$ . Nesterenko (1996) proved that  $\pi + e^\pi$  is irrational. In fact, he proved that  $\pi$ ,  $e^\pi$  and  $\Gamma(1/4)$  are algebraically independent, but it was not previously known that  $\pi + e^\pi$  was irrational.

Given a POLYNOMIAL equation

$$x^m + c_{m-1}x^{m-1} + \dots + c_0, \quad (1)$$

where  $c_i$  are INTEGERS, the roots  $x_i$  are either integral or irrational. If  $\cos(2\theta)$  is irrational, then so are  $\cos \theta$ ,  $\sin \theta$ , and  $\tan \theta$ .

Irrationality has not yet been established for  $2^e$ ,  $\pi^e$ ,  $\pi^{\sqrt{2}}$ , or  $\gamma$  (where  $\gamma$  is the EULER-MASCHERONI CONSTANT).

QUADRATIC SURDS are irrational numbers which have periodic CONTINUED FRACTIONS.

HURWITZ'S IRRATIONAL NUMBER THEOREM gives bounds of the form

$$\left| \alpha - \frac{p}{q} \right| < \frac{1}{L_n q^2} \quad (2)$$

for the best rational approximation possible for an arbitrary irrational number  $\alpha$ , where the  $L_n$  are called LAGRANGE NUMBERS and get steadily larger for each "bad" set of irrational numbers which is excluded.

The SERIES

$$\sum_{n=1}^{\infty} \frac{\sigma_k(n)}{n!}, \quad (3)$$

where  $\sigma_k(n)$  is the DIVISOR FUNCTION, is irrational for  $k = 1$  and  $2$ . The series

$$\sum_{n=1}^{\infty} \frac{1}{2^n - 1} = \sum_{n=1}^{\infty} \frac{d(n)}{2^n}, \quad (4)$$

where  $d(n)$  is the number of divisors of  $n$ , is also irrational, as are

$$\sum_{n=1}^{\infty} \frac{1}{q^n + r} \quad \text{for} \quad \sum_{n=1}^{\infty} \frac{(-1)^n}{q^n + r} \quad (5)$$

for  $q$  an INTEGER other than  $p, \pm 1$ , and  $r$  a RATIONAL NUMBER other than  $0$  or  $-q^n$  (Guy 1994).

### Irreducible Matrix

A SQUARE MATRIX which is not REDUCIBLE is said to be irreducible.

### Irreducible Polynomial

A POLYNOMIAL or polynomial equation is said to be irreducible if it cannot be factored into polynomials of lower degree over the same FIELD.

The number of binary irreducible polynomials of degree  $n$  is equal to the number of  $n$ -bead fixed NECKLACES of two colors: 1, 2, 3, 4, 6, 8, 14, 20, 36, ... (Sloane's A000031), the first few of which are given in the following table.

$n$	Polynomials
1	$x$
2	$x, x + 1$
3	$x, x^2 + x + 1, x + 1$
4	$x, x^3 + x + 1, x^3 + x^2 + 1, x + 1$

### Irreducible Representation

An irreducible representation of a GROUP is a representation for which there exists no UNITARY TRANSFORMATION which will transform the representation MATRIX into block diagonal form. The irreducible representation has a number of remarkable properties.

see also GROUP, ITÔ'S THEOREM, UNITARY TRANSFORMATION

### Irreducible Semiperfect Number

see PRIMITIVE PSEUDOPERFECT NUMBER

### Irreducible Tensor

Given a general second RANK TENSOR  $A_{ij}$  and a METRIC  $g_{ij}$ , define

$$\theta \equiv A_{ij} g^{ij} = A_i^i \quad (1)$$

$$\omega^i \equiv \epsilon^{ijk} A_{jk} \quad (2)$$

$$\sigma_{ij} \equiv \frac{1}{2}(A_{ij} + A_{ji}) - \frac{1}{3}g_{ij} A_k^k, \quad (3)$$

where  $\delta_{ij}$  is the KRONECKER DELTA and  $\epsilon^{ijk}$  is the LEVI-CIVITA SYMBOL. Then

$$\begin{aligned} \sigma_{ij} + \frac{1}{3}\theta g_{ij} + \frac{1}{2}\epsilon_{ijk}\omega^k \\ = [\frac{1}{2}(A_{ij} + A_{ji}) - \frac{1}{3}g_{ij} A_k^k] + \frac{1}{3}A_k^k g_{ij} + \frac{1}{2}\epsilon_{ijk}[\epsilon^{\lambda\mu k} A_{\lambda\mu}] \\ = \frac{1}{2}(A_{ij} + A_{ji}) + \frac{1}{2}(\delta_i^\lambda \delta_j^\mu - \delta_j^\mu \delta_i^\lambda) A_{\lambda\mu} \\ = \frac{1}{2}(A_{ij} + A_{ji}) + \frac{1}{2}(A_{ij} - A_{ji}) = A_{ij}, \end{aligned} \quad (4)$$

where  $\theta$ ,  $\omega^i$ , and  $\sigma_{ij}$  are TENSORS of RANK 0, 1, and 2.

see also TENSOR

### Irredundant Ramsey Number

Let  $G_1, G_2, \dots, G_t$  be a  $t$ -EDGE coloring of the COMPLETE GRAPH  $K_n$ , where for each  $i = 1, 2, \dots, t$ ,  $G_i$  is the spanning SUBGRAPH of  $K_n$  consisting of all EDGES colored with the  $i$ th color. The irredundant Ramsey number  $s(q_1, \dots, q_t)$  is the smallest INTEGER  $n$  such that for any  $t$ -EDGE coloring of  $K_n$ , the COMPLEMENT GRAPH  $\overline{G_i}$  has an irredundant set of size  $q_i$  for at least one  $i = 1, \dots, t$ . Irredundant Ramsey numbers were introduced by Brewster *et al.* (1989) and satisfy

$$s(q_1, \dots, q_t) \leq R(q_1, \dots, q_t).$$

For a summary, see Mynhardt (1992).

### Irreflexive

A RELATION  $R$  on a SET  $S$  is irreflexive provided that no element is related to itself; in other words,  $xRx$  for no  $x$  in  $S$ .

see also RELATION

### Irregular Pair

If  $p$  divides the NUMERATOR of the BERNOULLI NUMBER  $B_{2k}$  for  $0 < 2k < p - 1$ , then  $(p, 2k)$  is called an irregular pair. For  $p < 30000$ , the irregular pairs of various forms are  $p = 16843$  for  $(p, p - 3)$ ,  $p = 37$  for  $(p, p - 5)$ , none for  $(p, p - 7)$ , and  $p = 67,877$  for  $(p, p - 9)$ .

see also BERNOULLI NUMBER, IRREGULAR PRIME

### Irregular Prime

PRIMES for which Kummer's theorem on the unsolvability of FERMAT'S LAST THEOREM does not apply. An irregular prime  $p$  divides the NUMERATOR of one of the BERNOULLI NUMBERS  $B_{10}, B_{12}, \dots, B_{2p-2}$ , as shown by Kummer in 1850. The FERMAT EQUATION has no solutions for REGULAR PRIMES.

An INFINITE number of irregular PRIMES exist, as proven in 1915 by Jensen. The first few irregular primes are 37, 59, 67, 101, 103, 131, 149, 157, ... (Sloane's A000928). Of the 283,145 PRIMES less than  $4 \times 10^6$ , 111,597 (or 39.41%) are regular. The conjectured FRACTION is  $1 - e^{-1/2} \approx 39.35\%$  (Ribenoim 1996, p. 415).

### Irregular Singularity

Consider a second-order ORDINARY DIFFERENTIAL EQUATION

$$y'' + P(x)y' + Q(x)y = 0.$$

If  $P(x)$  and  $Q(x)$  remain FINITE at  $x = x_0$ , then  $x_0$  is called an ORDINARY POINT. If either  $P(x)$  or  $Q(x)$  diverges as  $x \rightarrow x_0$ , then  $x_0$  is called a singular point. If  $P(x)$  diverges more quickly than  $1/(x - x_0)$ , so  $(x - x_0)P(x)$  approaches INFINITY as  $x \rightarrow x_0$ , or  $Q(x)$  diverges more quickly than  $1/(x - x_0)^2 Q$  so that  $(x - x_0)^2 Q(x)$  goes to INFINITY as  $x \rightarrow x_0$ , then  $x_0$  is called an IRREGULAR SINGULARITY (or ESSENTIAL SINGULARITY).

Oxford University Press	0198
Springer-Verlag	0387
Wiley	0471

The International Standard Book Number (ISBN) is a 10-digit CODE which is used to identify a book uniquely. The first four digits specify the publisher, the next five digits the book, and the last digit  $d_{10}$  is a check digit which may be in the range 0–9 or X (where X equals 10). The check digit is computed from the equation

$$10d_1 + 9d_2 + 8d_3 + \dots + 2d_9 + d_{10} \equiv 0 \pmod{11}.$$

For example, the number for this book is 0-8493-9640-9, and

$$10 \cdot 0 + 9 \cdot 8 + 8 \cdot 4 + 7 \cdot 9 + 6 \cdot 3 + 5 \cdot 9 + 4 \cdot 6 + 3 \cdot 4 + 2 \cdot 0 + 1 \cdot 9 = 275 = 25 \cdot 11 \equiv 0 \pmod{11},$$

as required.

**Island**

If an integrable QUASIPERIODIC system is slightly perturbed so that it becomes nonintegrable, only a finite number of  $n$ -CYCLES remain as a result of MODE LOCKING. One will be elliptical and one will be hyperbolic.

Surrounding the ELLIPTIC FIXED POINT is a region of stable ORBITS which circle it, as illustrated above in the STANDARD MAP with  $K = 1.5$ . As the map is iteratively applied, the island is mapped to a similar structure surrounding the next point of the elliptic cycle. The map thus has a chain of islands, with the FIXED POINT alternating between ELLIPTIC (at the center of the islands) and HYPERBOLIC (between islands). Because the unperturbed system goes through an INFINITY of rational values, the perturbed system must have an INFINITE number of island chains.

see also MODE LOCKING, ORBIT (MAP), QUASIPERIODIC FUNCTION

**Isobaric Polynomial**

A POLYNOMIAL in which the sum of SUBSCRIPTS is the same in each term.

see also HOMOGENEOUS POLYNOMIAL

**Isochronous Curve**

see SEMICUBICAL PARABOLA, TAUTOCHRONE PROBLEM

**Isoclinal**

see ISOCLINE

**Isocline**

A graphical method of solving an ORDINARY DIFFERENTIAL EQUATION of the form

$$\frac{dy}{dx} = f(x, y)$$

by plotting a series of curves  $f(x, y) = [\text{const}]$ , then drawing a curve PERPENDICULAR to each curve such that it satisfies the initial condition. This curve is the solution to the ORDINARY DIFFERENTIAL EQUATION.

**Isoclinic Groups**

Two GROUPS  $G$  and  $H$  are said to be isoclinic if there are isomorphisms  $G/Z(G) \rightarrow H/Z(H)$  and  $G' \rightarrow H'$ , where  $Z(G)$  is the CENTER of the group, which identify the two commutator maps.

**Isodynamic Points**

The first and second isodynamic points of a TRIANGLE  $\triangle ABC$  can be constructed by drawing the triangle's ANGLE BISECTORS and EXTERIOR ANGLE BISECTORS. Each pair of bisectors intersects a side of the triangle (or its extension) in two points  $D_{i1}$  and  $D_{i2}$ , for  $i = 1, 2, 3$ . The three CIRCLES having  $D_{11}D_{12}$ ,  $D_{21}D_{22}$ , and  $D_{31}D_{32}$  as DIAMETERS are the APOLLONIUS CIRCLES  $C_1$ ,  $C_2$ , and  $C_3$ . The points  $S$  and  $S'$  in which the three APOLLONIUS CIRCLES intersect are the first and second isodynamic points, respectively.

$S$  and  $S'$  have TRIANGLE CENTER FUNCTIONS

$$\alpha = \sin(A \pm \frac{1}{3}\pi),$$

respectively. The ANTIPEDAL TRIANGLES of both points are EQUILATERAL and have AREAS

$$\Delta' = 2\Delta[\cot \omega \cot(\frac{1}{3}\pi)],$$

where  $\omega$  is the BROCARD ANGLE.

The isodynamic points are ISOGONAL CONJUGATES of the ISOGONIC CENTERS. They lie on the BROCARD AXIS. The distances from either isodynamic point to the VERTICES are inversely proportional to the sides. The PEDAL TRIANGLE of either isodynamic point is an EQUILATERAL TRIANGLE. An INVERSION with either

isodynamic point as the INVERSION CENTER transforms the triangle into an EQUILATERAL TRIANGLE.

The CIRCLE which passes through both the isodynamic points and the CENTROID of a TRIANGLE is known as the PARRY CIRCLE.

see also APOLLONIUS CIRCLES, BROCARD AXIS, CENTROID (TRIANGLE), ISOGONIC CENTERS, PARRY CIRCLE

### Isoenergetic Nondegeneracy

The condition for isoenergetic nondegeneracy for a Hamiltonian

$$H = H_0(\mathbf{I}) + \epsilon H_1(\mathbf{I}, \boldsymbol{\theta})$$

is

$$\begin{vmatrix} \frac{\partial^2 H_0}{\partial I_i \partial I_j} & \frac{\partial H_0}{\partial I_i} \\ \frac{\partial H_0}{\partial I_j} & 0 \end{vmatrix} \neq 0,$$

which guarantees the EXISTENCE on every energy level surface of a set of invariant tori whose complement has a small MEASURE.

### Isogonal Conjugate

The isogonal conjugate  $X^{-1}$  of a point  $X$  in the plane of the TRIANGLE  $\triangle ABC$  is constructed by reflecting the lines  $AX$ ,  $BX$ , and  $CX$  about the ANGLE BISECTORS at  $A$ ,  $B$ , and  $C$ . The three reflected lines CONCUR at the isogonal conjugate. The TRILINEAR COORDINATES of the isogonal conjugate of the point with coordinates

$$\alpha : \beta : \gamma$$

are

$$\alpha^{-1} : \beta^{-1} : \gamma^{-1}.$$

Isogonal conjugation maps the interior of a TRIANGLE onto itself. This mapping transforms lines onto CONIC

SECTIONS that CIRCUMSCRIBE the TRIANGLE. The type of CONIC SECTION is determined by whether the line  $d$  meets the CIRCUMCIRCLE  $C'$ ,

1. If  $d$  does not intersect  $C'$ , the isogonal transform is an ELLIPSE;
2. If  $d$  is tangent to  $C'$ , the transform is a PARABOLA;
3. If  $d$  cuts  $C'$ , the transform is a HYPERBOLA, which is a RECTANGULAR HYPERBOLA if the line passes through the CIRCUMCENTER

(Casey 1893, Vandeghen 1965).

The isogonal conjugate of a point on the CIRCUMCIRCLE is a POINT AT INFINITY (and conversely). The sides of the PEDAL TRIANGLE of a point are PERPENDICULAR to the connectors of the corresponding VERTICES with the isogonal conjugate. The isogonal conjugate of a set of points is the LOCUS of their isogonal conjugate points.

The product of ISOTOMIC and isogonal conjugation is a COLLINEATION which transforms the sides of a TRIANGLE to themselves (Vandeghen 1965).

 Vandeghen, A. "Some Remarks on the Isogonal and Cevian Transforms. Alignments of Remarkable Points of a Triangle." *Amer. Math. Monthly* **72**, 1091–1094, 1965.

### Isogonal Line

The line  $L'$  through a TRIANGLE VERTEX obtained by reflecting an initial line  $L$  (also through a VERTEX) about the ANGLE BISECTOR. If three lines from the VERTICES of a TRIANGLE  $\triangle ABC$  are CONCURRENT at  $X = L_1 L_2 L_3$ , then their isogonal lines are also CONCURRENT, and the point of concurrence  $X' = L'_1 L'_2 L'_3$  is called the ISOGONAL CONJUGATE point.

see also ISOGONAL CONJUGATE

#### References

- Johnson, R. A. *Modern Geometry: An Elementary Treatise on the Geometry of the Triangle and the Circle*. Boston, MA: Houghton Mifflin, pp. 153–157, 1929.

**Isogonic Centers**

The first isogonic center  $F_1$  of a TRIANGLE is the FERMAT POINT. The second isogonic center  $F_2$  is constructed analogously with the first isogonic center except that for  $F_2$ , the EQUILATERAL TRIANGLES are constructed on the same side of the opposite VERTEX. The second isogonic center has TRIANGLE CENTER FUNCTION

$$\alpha = \csc(A - \tfrac{1}{3}\pi).$$

Its ANTIPEDAL TRIANGLE is EQUILATERAL and has AREA

$$2\Delta = [-1 + \cot \omega \cot(\tfrac{1}{3}\pi)],$$

where  $\omega$  is the BROCARD ANGLE.

The first and second isogonic centers are ISOGONAL CONJUGATES of the ISODYNAMIC POINTS.

**Isograph**

The substitution of  $re^{i\theta}$  for  $z$  in a POLYNOMIAL  $p(z)$ .  $p(z)$  is then plotted as a function of  $\theta$  for a given  $r$  in the COMPLEX PLANE. By varying  $r$  so that the curve passes through the ORIGIN, it is possible to determine a value for one ROOT of the POLYNOMIAL.

**Isohedral Tiling**

Let  $S(T)$  be the group of symmetries which map a MONOHEDRAL TILING  $T$  onto itself. The TRANSITIVITY CLASS of a given tile  $T$  is then the collection of all tiles to which  $T$  can be mapped by one of the symmetries of  $S(T)$ . If  $T$  has  $k$  TRANSITIVITY CLASSES, then  $T$  is said to be  $k$ -isohedral. Berglund (1993) gives examples of  $k$ -isohedral tilings for  $k = 1, 2$ , and  $4$ .

see also ANISOHEDRAL TILING

**Isolated Point**

A point on a curve, also known as an ACNODE or HERMIT POINT, which has no other points in its NEIGHBORHOOD.

**Isolated Singularity**

An isolated singularity is a SINGULARITY for which there exists a (small) REAL NUMBER  $\epsilon$  such that there are no other SINGULARITIES within a NEIGHBORHOOD of radius  $\epsilon$  centered about the SINGULARITY.

The types of isolated singularities possible for CUBIC SURFACES have been classified (Schläfli 1864, Cayley 1869, Bruce and Wall 1979) and are summarized in the following table from Fischer (1986).

Double Pt. Name	Symbol	Normal Form	Coxeter Diagram
conic	$C_2$	$x^2 + y^2 + z^2$	$A_1$
biplanar	$B_3$	$x^2 + y^2 + z^3$	$A_2$
biplanar	$B_4$	$x^2 + y^2 + z^4$	$A_3$
biplanar	$B_5$	$x^2 + y^2 + z^5$	$A_4$
biplanar	$B_6$	$x^2 + y^2 + z^6$	$A_5$
uniplanar	$U_6$	$x^2 + z(y^2 + z^2)$	$D_4$
uniplanar	$U_7$	$x^2 + z(y^2 + z^3)$	$D_5$
uniplanar	$U_8$	$x^2 + y^3 + z^4$	$E_6$
elliptic cone pt.	—	$xy^2 - 4z^3$ $-g_2x^2y + g_3x^3$	$\tilde{E}_6$

**Isolating Integral**

An integral of motion which restricts the PHASE SPACE available to a DYNAMICAL SYSTEM.

**Isometry**

A BIJECTIVE MAP between two METRIC SPACES that preserves distances, i.e.,

$$d(f(x), f(y)) = d(x, y),$$

where  $f$  is the MAP and  $d(a, b)$  is the DISTANCE function.

An isometry of the PLANE is a linear transformation which preserves length. Isometries include ROTATION, TRANSLATION, REFLECTION, GLIDES, and the IDENTITY MAP. If an isometry has more than one FIXED

POINT, it must be either the identity transformation or a reflection. Every isometry of period two (two applications of the transformation preserving lengths in the original configuration) is either a reflection or a half turn rotation. Every isometry in the plane is the product of at most three reflections (at most two if there is a FIXED POINT). Every finite group of isometries has at least one FIXED POINT.

see also DISTANCE, EUCLIDEAN MOTION, HJELMSLEV'S THEOREM, LENGTH (CURVE), REFLECTION, ROTATION, TRANSLATION

#### References

### Isometric Latitude

An AUXILIARY LATITUDE which is directly proportional to the spacing of parallels of LATITUDE from the equator on an ellipsoidal MERCATOR PROJECTION. It is defined by

$$\psi = \ln \left| \tan \left( \frac{1}{4}\pi + \frac{1}{2}\phi \right) \left( \frac{1 - e \sin \phi}{1 + e \sin \phi} \right)^{e/2} \right|, \quad (1)$$

where the symbol  $\tau$  is sometimes used instead of  $\psi$ . The isometric latitude is related to the CONFORMAL LATITUDE by

$$\psi = \ln \tan \left( \frac{1}{4}\pi + \frac{1}{2}\chi \right). \quad (2)$$

The inverse is found by iterating

$$\phi = 2 \tan^{-1} \left[ \exp(\psi) \left( \frac{1 + e \sin \phi}{1 - e \sin \phi} \right)^{e/2} \right] - \frac{1}{2}\pi, \quad (3)$$

with the first trial as

$$\phi_0 = 2 \tan^{-1}(e^\psi) - \frac{1}{2}\pi. \quad (4)$$

see also LATITUDE

### Isomorphic Graphs

Two GRAPHS which contain the same number of VERTICES connected in the same way are said to be isomorphic. Formally, two graphs  $G$  and  $H$  with VERTICES  $V_n = \{1, 2, \dots, n\}$  are said to be isomorphic if there is a PERMUTATION  $p$  of  $V_n$  such that  $\{u, v\}$  is in the set of EDGES  $E(G)$  IFF  $\{p(u), p(v)\}$  is in the set of EDGES  $E(H)$ .

#### References

Chartrand, G. "Isomorphic Graphs." §2.2 in *Introductory Graph Theory*. New York: Dover, pp. 32–40, 1985.

### Isomorphic Groups

Two GROUPS are isomorphic if the correspondence between them is ONE-TO-ONE and the "multiplication" table is preserved. For example, the POINT GROUPS  $C_2$  and  $D_1$  are isomorphic GROUPS, written  $C_2 \cong D_1$  or  $C_2 \doteq D_1$  (Shanks 1993). Note that the symbol  $\cong$  is also used to denote geometric CONGRUENCE.

#### References

Shanks, D. *Solved and Unsolved Problems in Number Theory*, 4th ed. New York: Chelsea, 1993.

### Isomorphic Posets

Two POSETS are said to be isomorphic if their "structures" are entirely analogous. Formally, POSETS  $P = (X, \leq)$  and  $Q = (X', \leq')$  are isomorphic if there is a BIJECTION  $f$  from  $X$  to  $X'$  such that  $x \leq x'$  precisely when  $f(x) \leq' f(x')$ .

### Isomorphism

Isomorphism is a very general concept which appears in several areas of mathematics. Formally, an isomorphism is BIJECTIVE MORPHISM. Informally, an isomorphism is a map which preserves sets and relations among elements.

A space isomorphism is a VECTOR SPACE in which addition and scalar multiplication are preserved. An isomorphism of a TOPOLOGICAL SPACE is called a HOMEOMORPHISM.

Two groups  $G_1$  and  $G_2$  with binary operators  $+$  and  $\times$  are isomorphic if there exists a map  $f: G_1 \mapsto G_2$  which satisfies

$$f(x + y) = f(x) \times f(y).$$

An isomorphism preserves the identities and inverses of a GROUP. A GROUP which is isomorphic to itself is called an AUTOMORPHISM.

see also AUTOMORPHISM, AX-KOCHEN ISOMORPHISM THEOREM, HOMEOMORPHISM, MORPHISM

### Isoperimetric Inequality

Let a PLANE figure have AREA  $A$  and PERIMETER  $p$ . Let the CIRCLE of PERIMETER  $p$  have RADIUS  $r$ . Then

$$\frac{4\pi A}{p^2} \leq 1,$$

where the quantity on the left is known as the ISOPERIMETRIC QUOTIENT.

**Isoperimetric Point**

The point  $S'$  which makes the PERIMETERS of the TRIANGLES  $\triangle BS'C$ ,  $\triangle CS'A$ , and  $\triangle AS'B$  equal. The isoperimetric point exists IFF the largest ANGLE of the triangle satisfies

$$\max(A, B, C) < 2 \sin^{-1}\left(\frac{4}{5}\right) \approx 1.85459 \text{ rad} \approx 106.26^\circ,$$

or equivalently

$$a + b + c > 4R + r,$$

where  $a$ ,  $b$ , and  $c$  are the side lengths of  $\triangle ABC$ ,  $r$  is the INRADIUS, and  $R$  is the CIRCUMRADIUS. The isoperimetric point is also the center of the outer SODDY CIRCLE of  $\triangle ABC$  and has TRIANGLE CENTER FUNCTION

$$\alpha = 1 - \frac{2\Delta}{a(b+c-a)} = \sec\left(\frac{1}{2}A\right) \cos\left(\frac{1}{2}B\right) \cos\left(\frac{1}{2}C\right) - 1.$$

**Isoperimetric Problem**

Find a closed plane curve of a given length which encloses the greatest AREA. The solution is a CIRCLE. If the class of curves to be considered is limited to smooth curves, the isoperimetric problem can be stated symbolically as follows: find an arc with parametric equations  $x = x(t)$ ,  $y = y(t)$  for  $t \in [t_1, t_2]$  such that  $x(t_1) = x(t_2)$ ,  $y(t_1) = y(t_2)$  (where no further intersections occur) constrained by

$$l = \int_{t_1}^{t_2} \sqrt{x'^2 + y'^2} dt$$

such that

$$A = \frac{1}{2} \int_{t_1}^{t_2} (xy' - x'y) dt$$

is a MAXIMUM.

**Isoperimetric Quotient**

A quantity defined in the ISOPERIMETRIC INEQUALITY

$$Q \equiv \frac{4\pi A}{p^2}.$$

see also ISOPERIMETRIC INEQUALITY

**Isoperimetric Theorem**

Of all convex  $n$ -gons of a given PERIMETER, the one which maximizes AREA is the regular  $n$ -gon.

see also ISOPERIMETRIC INEQUALITY, ISOPERIMETRIC PROBLEM

**Isopleth**

see EQUIPOTENTIAL CURVE

**Isoptic Curve**

For a given curve  $C$ , consider the locus of the point  $P$  from where the TANGENTS from  $P$  to  $C$  meet at a fixed given ANGLE. This is called an isoptic curve of the given curve.

Curve	Isoptic
cycloid	curtate or prolate cycloid
epicycloid	epitrochoid
hypocycloid	hypotrochoid
parabola	hyperbola
sinusoidal spiral	sinusoidal spiral

see also ORTHOPTIC CURVE

**Isosceles Tetrahedron**

A nonregular TETRAHEDRON in which each pair of opposite EDGES are equal such that all triangular faces are congruent. A TETRAHEDRON is isosceles IFF the sum of the face angles at each VERTEX is  $180^\circ$ , and IFF its INSPIHERE and CIRCUMSPHERE are concentric.

The only way for all the faces of a TETRAHEDRON to have the same PERIMETER or to have the same AREA is for them to be fully congruent, in which case the tetrahedron is isosceles.

see also CIRCUMSPHERE, INSPHERE, ISOSCELES TRIANGLE, TETRAHEDRON

### Isosceles Triangle

A TRIANGLE with two equal sides (and two equal ANGLES). The name derives from the Greek *iso* (same) and *skelos* (LEG). The height of the above isosceles triangle can be found from the PYTHAGOREAN THEOREM as

$$h = \sqrt{b^2 - \frac{1}{4}a^2}. \quad (1)$$

The AREA is therefore given by

$$A = \frac{1}{2}ah = \frac{1}{2}a\sqrt{b^2 - \frac{1}{4}a^2}. \quad (2)$$

There is a surprisingly simple relationship between the AREA and VERTEX ANGLE  $\theta$ . As shown in the above diagram, simple TRIGONOMETRY gives

$$h = R \cos\left(\frac{1}{2}\theta\right) \quad (3)$$

$$a = R \sin\left(\frac{1}{2}\theta\right), \quad (4)$$

so the AREA is

$$A = \frac{1}{2}(2a)h = ah = R^2 \cos\left(\frac{1}{2}\theta\right) \sin\left(\frac{1}{2}\theta\right) = \frac{1}{2}R^2 \sin \theta. \quad (5)$$

No set of  $n > 6$  points in the PLANE can determine only ISOSCELES TRIANGLES.

### Isoscelizer

An isoscelizer of an ANGLE  $A$  in a TRIANGLE  $\Delta ABC$  is a LINE SEGMENT  $I_{AB}I_{AC}$  where  $I_{AB}$  lies on  $AB$  and  $I_{AC}$  on  $AC$  such that  $\Delta AI_{AB}I_{AC}$  is an ISOSCELES TRIANGLE.

see also CONGRUENT ISOSCELIZERS POINT, ISOSCELES TRIANGLE, YFF CENTER OF CONGRUENCE

### Isospectral Manifolds

DRUMS that sound the same, i.e., have the same eigenfrequency spectrum. Two drums with differing AREA, PERIMETER, or GENUS can always be distinguished. However, Kac (1966) asked if it was possible to construct differently shaped drums which have the same eigenfrequency spectrum. This question was answered in the affirmative by Gordon *et al.* (1992). Two such isospectral manifolds are shown in the right figure above (Cipra 1992).

**Isothermal Parameterization**

A parameterization is isothermal if, for  $\zeta \equiv u + iv$  and

$$\phi_k(\zeta) = \frac{\partial x_k}{\partial u} - i \frac{\partial x_k}{\partial v},$$

the identity

$$\phi_1^2(\zeta) + \phi_2^2(\zeta) + \phi_3^2(\zeta) = 0$$

holds.

see also MINIMAL SURFACE, TEMPERATURE

**Isotomic Conjugate Point**

The point of concurrence  $Q$  of the ISOTOMIC LINES relative to a point  $P$ . The isotomic conjugate  $\alpha' : \beta' : \gamma'$  of a point with TRILINEAR COORDINATES  $\alpha : \beta : \gamma$  is

$$(a^2\alpha)^{-1} : (b^2\beta)^{-1} : (c^2\gamma)^{-1}. \quad (1)$$

The isotomic conjugate of a LINE  $d$  having trilinear equation

$$l\alpha + m\beta + n\gamma \quad (2)$$

is a CONIC SECTION circumscribed on the TRIANGLE  $\Delta ABC$  (Casey 1893, Vandeghen 1965). The isotomic conjugate of the LINE AT INFINITY having trilinear equation

$$a\alpha + b\beta + c\gamma = 0 \quad (3)$$

is STEINER'S ELLIPSE

$$\frac{\beta'\gamma'}{a} + \frac{\gamma'\alpha'}{b} + \frac{\alpha'\beta'}{c} = 0 \quad (4)$$

(Vandeghen 1965). The type of CONIC SECTION to which  $d$  is transformed is determined by whether the line  $d$  meets STEINER'S ELLIPSE  $E$ .

1. If  $d$  does not intersect  $E$ , the isotomic transform is an ELLIPSE.
2. If  $d$  is tangent to  $E$ , the transform is a PARABOLA.
3. If  $d$  cuts  $E$ , the transform is a HYPERBOLA, which is a RECTANGULAR HYPERBOLA if the line passes through the isotomic conjugate of the ORTHOCENTER

(Casey 1893, Vandeghen 1965).

There are four points which are isotomically self-conjugate: the CENTROID  $M$  and each of the points of intersection of lines through the VERTICES PARALLEL to the opposite sides. The isotomic conjugate of the EULER LINE is called JERABEK'S HYPERBOLA (Casey 1893, Vandeghen 1965).

Vandeghen (1965) calls the transformation taking points to their isotomic conjugate points the CEVIAN TRANSFORM. The product of isotomic and ISOGONAL is a COLLINEATION which transforms the sides of a TRIANGLE to themselves (Vandeghen 1965).

**Isotomic Lines**

Given a point  $P$  in the interior of a TRIANGLE  $\Delta A_1A_2A_3$ , draw the CEVIANS through  $P$  from each VERTEX which meet the opposite sides at  $P_1$ ,  $P_2$ , and  $P_3$ . Now, mark off point  $Q_1$  along side  $A_2A_3$  such that  $A_3P_1 = A_2Q_1$ , etc., i.e., so that  $Q_i$  and  $P_i$  are equidistance from the MIDPOINT of  $A_jA_k$ . The lines  $A_1Q_1$ ,  $A_2Q_2$ , and  $A_3Q_3$  then coincide in a point  $Q$  known as the ISOTOMIC CONJUGATE POINT.

see also CEVIAN, ISOTOMIC CONJUGATE POINT, MID-POINT

**Isotone Map**

A MAP which is monotone increasing and therefore order-preserving.

**Isotope**

To rearrange without cutting or pasting.

**Isotopy**

A HOMOTOPY from one embedding of a MANIFOLD  $M$  in  $N$  to another such that at every time, it is an embedding. The notion of isotopy is category independent, so notions of topological, piecewise-linear, smooth, isotopy (and so on) exist. When no explicit mention is made, "isotopy" usually means "smooth isotopy."

see also AMBIENT ISOTOPY, REGULAR ISOTOPY

**Isotropic Tensor**

A TENSOR which has the same components in all rotated coordinate systems.

rank	isotropic tensors
0	all
1	none
2	Kronecker delta
3	1
4	3

**Isovolume Problem**

Find the surface enclosing the maximum volume per unit surface AREA  $I \equiv V/S$ . The solution is a SPHERE, which has

$$I_{\text{sphere}} = \frac{\frac{4}{3}\pi r^3}{4\pi r^2} = \frac{1}{3}r.$$

see BRIDGE (GRAPH)

**Iterated Exponential Constants**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

Euler (Le Lionnais 1983) and Eisenstein (1844) showed

that the function  $h(x) = x^{x^{x^{\cdots}}}$ , where  $x^{x^x}$  is an abbreviation for  $x^{(x^x)}$ , converges only for  $e^{-e} \leq x \leq e^{1/e}$ , that is,  $0.0659... \leq x \leq 1.44466...$ . The value it converges to is the inverse of  $x^{1/x}$ , which has a closed form expression in terms of LAMBERT'S W-FUNCTION,

$$h(z) = \frac{W(-\ln z)}{-\ln z} \quad (1)$$

(Corless *et al.*). Knoebel (1981) gives

$$h(z) = 1 + \ln x + \frac{3^2(\ln z)^2}{3!} + \frac{4^3(\ln z)^3}{4!} + \dots \quad (2)$$

(Vardi 1991). A CONTINUED FRACTION due to Khovanskii (1963) is

$$x^{1/x} = 1 + \frac{2(x-1)}{x^2 + 1 - \frac{(x^2-1)(x-1)^2}{3x(x+1) - \frac{(4x^2-1)(x-1)^2}{5x(x+1) - \frac{(9x^2-1)(x-1)^2}{7x(x+1) - \dots}}}} \quad (3)$$

The function  $g(x) = x^{(1/x)^{(1/x)^{\cdots}}}$  converges only for  $e^{-1/e} \leq x \leq e^e$ , that is,  $0.692... \leq x \leq 15.154...$ . The value it converges to is the inverse of  $x^x$ .

Some interesting related integrals are

$$\int_0^1 x^x dx = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^n} = 0.7834305107... \quad (4)$$

$$\int_0^1 x^{-x} dx = \sum_{n=1}^{\infty} \frac{1}{n^n} = 1.2912859971... \quad (5)$$

(Spiegel 1968, Abramowitz and Stegun 1972).

**Itô's Theorem**

The dimension  $d$  of any IRREDUCIBLE REPRESENTATION of a GROUP  $G$  must be a DIVISOR of the index of each maximal normal Abelian SUBGROUP of  $G$ .

see also ABELIAN GROUP, IRREDUCIBLE REPRESENTATION, SUBGROUP

References

- Lomont, J. S. *Applications of Finite Groups*. New York: Dover, p. 55, 1993.

**Iverson Bracket**

Let  $S$  be a mathematical statement, then the Iverson bracket is defined by

$$[S] \equiv \begin{cases} 0 & \text{if } S \text{ is true} \\ 1 & \text{if } S \text{ is false.} \end{cases}$$

This notation conflicts with the brackets sometimes used to denote the FLOOR FUNCTION. For this reason, and because of the elegant symmetry of the FLOOR FUNCTION and CEILING FUNCTION symbols  $\lfloor x \rfloor$  and  $\lceil x \rceil$ , the use of  $[x]$  to denote the FLOOR FUNCTION should be deprecated.

## J

j

The symbol used by engineers and some physicists to denote  $i$ , the IMAGINARY NUMBER  $\sqrt{-1}$ .

## j-Conductor

see FREY CURVE

## j-Function

The  $j$ -function is defined as

$$j(q) \equiv 1728J(\sqrt{q}), \quad (1)$$

where

$$J(q) \equiv \frac{4}{27} \frac{[1 - \lambda(q) + \lambda^2(q)]^3}{\lambda^2(q)[1 - \lambda(q)]^2} \quad (2)$$

is KLEIN'S ABSOLUTE INVARIANT,  $\lambda(q)$  the ELLIPTIC LAMBDA FUNCTION

$$\lambda(q) \equiv k^2(q) = \left[ \frac{\vartheta_2(q)}{\vartheta_3(q)} \right]^4, \quad (3)$$

and  $\vartheta_i$  a THETA FUNCTION. This function can also be specified in terms of the WEBER FUNCTIONS  $f$ ,  $f_1$ ,  $f_2$ ,  $\gamma_2$ , and  $\gamma_3$  as

$$j(z) = \frac{[f^{24}(z) - 16]^3}{f^{24}(z)} \quad (4)$$

$$= \frac{[f_1^{24}(z) + 16]^3}{f_1^{24}(z)} \quad (5)$$

$$= \frac{[f_2^{24}(z) + 16]^3}{f_2^{24}(z)} \quad (6)$$

$$= \gamma_2^3(z) \quad (7)$$

$$= \gamma_3^2(z) + 1728 \quad (8)$$

(Weber 1902, p. 179; Atkin and Morain 1993).

The  $j$ -function is MEROMORPHIC function on the upper half of the COMPLEX PLANE which is invariant with respect to the SPECIAL LINEAR GROUP  $SL(2, Z)$ . It has a FOURIER SERIES

$$j(q) = \sum_{n=-\infty}^{\infty} a_n q^n, \quad (9)$$

for the NOME

$$q \equiv e^{2\pi it} \quad (10)$$

with  $\Im[t] > 0$ . The coefficients in the expansion of the  $j$ -function satisfy:

1.  $a_n = 0$  for  $n < -1$  and  $a_{-1} = 1$ ,
2. all  $a_n$ s are INTEGERS with fairly limited growth with respect to  $n$ , and
3.  $j(q)$  is an ALGEBRAIC NUMBER, sometimes a RATIONAL NUMBER, and sometimes even an INTEGER at certain very special values of  $q$  (or  $t$ ).

The latter result is the end result of the massive and beautiful theory of COMPLEX multiplication and the first step of Kronecker's so-called "JUGENDTRAUM."

Then all of the COEFFICIENTS in LAURENT SERIES

$$j(q) = \frac{1}{q} + 744 + 196884q + 21494760q^2 + 864299970q^3 + 20245856256q^4 + 333202640600q^5 + \dots \quad (11)$$

(Sloane's A000521) are POSITIVE INTEGERS (Rankin 1977). Let  $d$  be a POSITIVE SQUAREFREE INTEGER, and define

$$t \equiv \begin{cases} i\sqrt{d} & \text{for } d \equiv 1 \text{ or } 2 \pmod{4} \\ \frac{1}{2}(1 + i\sqrt{d}) & \text{for } d \equiv 3 \pmod{4}. \end{cases} \quad (12)$$

Then the NOME is

$$q \equiv e^{i\pi\tau} = \begin{cases} e^{2\pi i(i\sqrt{d})} \\ e^{2\pi i(1+i\sqrt{d})/2} \end{cases} = \begin{cases} e^{-2\pi\sqrt{d}} & \text{for } d \equiv 1 \text{ or } 2 \pmod{4} \\ -e^{-\pi\sqrt{d}} & \text{for } d \equiv 3 \pmod{4}. \end{cases} \quad (13)$$

It then turns out that  $j(q)$  is an ALGEBRAIC INTEGER of degree  $h(-d)$ , where  $h(-d)$  is the CLASS NUMBER of the DISCRIMINANT  $-d$  of the QUADRATIC FIELD  $\mathbb{Q}(\sqrt{-d})$  (Silverman 1986). The first term in the LAURENT SERIES is then  $q^{-1} = e^{-2\pi\sqrt{-d}}$  or  $-e^{-\pi\sqrt{-d}}$ , and all the later terms are POWERS of  $q^{-1}$ , which are small numbers. The larger  $n$ , the faster the series converges. If  $h(-d) = 1$ , then  $j(q)$  is a ALGEBRAIC INTEGER of degree 1, i.e., just a plain INTEGER. Furthermore, the INTEGER is a perfect CUBE.

The numbers whose LAURENT SERIES give INTEGERS are those with CLASS NUMBER 1. But these are precisely the HEEGNER NUMBERS  $-1, -2, -3, -7, -11, -19, -43, -67, -163$ . The greater (in ABSOLUTE VALUE) the HEEGNER NUMBER  $d$ , the closer to an INTEGER is the expression  $e^{\pi\sqrt{-d}}$ , since the initial term in  $j(q)$  is the largest and subsequent terms are the smallest. The best approximations with  $h(-d) = 1$  are therefore

$$e^{\pi\sqrt{43}} \approx 960^3 + 744 - 2.2 \times 10^{-4} \quad (14)$$

$$e^{\pi\sqrt{67}} \approx 5280^3 + 744 - 1.3 \times 10^{-6} \quad (15)$$

$$e^{\pi\sqrt{163}} \approx 640320^3 + 744 - 7.5 \times 10^{-13}. \quad (16)$$

The exact values of  $j(q)$  corresponding to the HEEGNER NUMBERS are

$$j(-e^{-\pi}) = 12^3 \quad (17)$$

$$j(e^{-2\pi\sqrt{2}}) = 20^3 \quad (18)$$

$$j(-e^{-\pi\sqrt{3}}) = 0^3 \quad (19)$$

$$j(-e^{-\pi\sqrt{7}}) = -15^3 \quad (20)$$

$$j(-e^{-\pi\sqrt{11}}) = -32^3 \quad (21)$$

$$j(-e^{-\pi\sqrt{19}}) = -96^3 \quad (22)$$

$$j(-e^{-\pi\sqrt{43}}) = -960^3 \quad (23)$$

$$j(-e^{-\pi\sqrt{67}}) = -5280^3 \quad (24)$$

$$j(-e^{-\pi\sqrt{163}}) = -640320^3. \quad (25)$$

(The number 5280 is particularly interesting since it is also the number of feet in a mile.) The ALMOST INTEGER generated by the last of these,  $e^{\pi\sqrt{163}}$  (corresponding to the field  $\mathbb{Q}(\sqrt{-163})$  and the IMAGINARY quadratic field of maximal discriminant), is known as the RAMANUJAN CONSTANT.

$e^{\pi\sqrt{22}}$ ,  $e^{\pi\sqrt{37}}$ , and  $e^{\pi\sqrt{58}}$  are also ALMOST INTEGERS. These correspond to binary quadratic forms with discriminants  $-88$ ,  $-148$ , and  $-232$ , all of which have CLASS NUMBER two and were noted by Ramanujan (Berndt 1994).

It turns out that the  $j$ -function also is important in the CLASSIFICATION THEOREM for finite simple groups, and that the factors of the orders of the SPORADIC GROUPS, including the celebrated MONSTER GROUP, are also related.

#### *j*-Invariant

An invariant of an ELLIPTIC CURVE closely related to the DISCRIMINANT and defined by

$$j(E) \equiv \frac{2^8 3^3 a^3}{4a^3 + 27b^2}.$$

The determination of  $j$  as an ALGEBRAIC INTEGER in the QUADRATIC FIELD  $\mathbb{Q}(j)$  is discussed by Greenhill (1891), Weber (1902), Berwick (1928), Watson (1938), Gross and Zaiger (1985), and Dorman (1988). The norm of  $j$  in  $\mathbb{Q}(j)$  is the CUBE of an INTEGER in  $\mathbb{Z}$ .

#### Jackson's Difference Fan

If, after constructing a DIFFERENCE TABLE, no clear pattern emerges, turn the paper through an ANGLE of  $60^\circ$  and compute a new table. If necessary, repeat the process. Each ROTATION reduces POWERS by 1, so the sequence  $\{k^n\}$  multiplied by any POLYNOMIAL in  $n$  is reduced to 0s by a  $k$ -fold difference fan.

**Jackson's Theorem**

Jackson's theorem is a statement about the error  $E_n(f)$  of the best uniform approximation to a REAL FUNCTION  $f(x)$  on  $[-1, 1]$  by REAL POLYNOMIALS of degree at most  $n$ . Let  $f(x)$  be of bounded variation in  $[-1, 1]$  and let  $M'$  and  $V'$  denote the least upper bound of  $|f(x)|$  and the total variation of  $f(x)$  in  $[-1, 1]$ , respectively. Given the function

$$F(x) = F(-1) + \int_{-1}^x f(x) dx, \quad (1)$$

then the coefficients

$$a_n = \frac{1}{2}(2n+1) \int_{-1}^1 F(x) P_n(x) dx \quad (2)$$

of its LEGENDRE SERIES, where  $P_n(x)$  is a LEGENDRE POLYNOMIAL, satisfy the inequalities

$$|a_n| < \begin{cases} \frac{6}{\sqrt{\pi}}(M' + V')n^{-3/2} & \text{for } n \geq 1 \\ \frac{4}{\sqrt{\pi}}(M' + V')n^{-3/2} & \text{for } n \geq 2. \end{cases} \quad (3)$$

Moreover, the LEGENDRE SERIES of  $F(x)$  converges uniformly and absolutely to  $F(x)$  in  $[-1, 1]$ .

Bernstein strengthened Jackson's theorem to

$$2nE_{2n}(\alpha) \leq \frac{4n}{\pi(2n+1)} < \frac{2}{\pi} = 0.6366. \quad (4)$$

A specific application of Jackson's theorem shows that if

$$\alpha(x) = |x|, \quad (5)$$

then

$$E_n(\alpha) \leq \frac{6}{n}. \quad (6)$$

**Jaco-Shalen-Johannson Torus Decomposition**

Irreducible orientable COMPACT 3-MANIFOLDS have a canonical (up to ISOTOPY) minimal collection of disjointly EMBEDDED incompressible TORI such that each component of the 3-MANIFOLD removed by the TORI is either "atoroidal" or "Seifert-fibered."

**Jacobi Algorithm**

A method which can be used to solve a TRIDIAGONAL MATRIX equation with largest absolute values in each row and column dominated by the diagonal element. Each diagonal element is solved for, and an approximate value plugged in. The process is then iterated until it converges. This algorithm is a stripped-down version of the JACOBI METHOD of matrix diagonalization.

**Jacobi-Anger Expansion**

$$e^{iz \cos \theta} = \sum_{n=-\infty}^{\infty} i^n J_n(z) e^{in\theta},$$

where  $J_n(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. The identity can also be written

$$e^{iz \cos \theta} = J_0(z) + 2 \sum_{n=1}^{\infty} i^n J_n(z) \cos(n\theta).$$

This expansion represents an expansion of plane waves into a series of cylindrical waves.

see also BESSEL FUNCTION OF THE FIRST KIND

**Jacobi's Curvature Theorem**

The principal normal indicatrix of a closed space curve with nonvanishing curvature bisects the AREA of the unit sphere if it is embedded.

**Jacobi's Determinant Identity**

Let

$$A = \begin{bmatrix} B & D \\ E & C \end{bmatrix} \quad (1)$$

$$A^{-1} = \begin{bmatrix} W & X \\ Y & Z \end{bmatrix}, \quad (2)$$

where  $B$  and  $W$  are  $k \times k$  MATRICES. Then

$$(\det Z)(\det A) = \det B. \quad (3)$$

The proof follows from equating determinants on the two sides of the block matrices

$$\begin{bmatrix} B & D \\ E & C \end{bmatrix} \begin{bmatrix} I & X \\ O & Z \end{bmatrix} = \begin{bmatrix} B & O \\ E & I \end{bmatrix}, \quad (4)$$

where  $I$  is the IDENTITY MATRIX and  $O$  is the zero matrix.

**Jacobi Differential Equation**

$$(1-x^2)y'' + [\beta - \alpha - (\alpha + \beta + 2)x]y' + n(n + \alpha + \beta + 1)y = 0 \quad (1)$$

or

$$\frac{d}{dx}[(1-x)^{\alpha+1}(1+x)^{\beta+1}y'] + n(n + \alpha + \beta + 1)(1-x)^{\alpha}(1+x)^{\beta}y = 0. \quad (2)$$

The solutions are JACOBI POLYNOMIALS. They can be transformed to

$$\frac{d^2u}{dx^2} + \left[ \frac{1}{4} \frac{1-\alpha^2}{(1-x)^2} + \frac{1}{4} \frac{1-\beta^2}{(1+x)^2} + \frac{n(n + \alpha + \beta + 1) + \frac{1}{2}(\alpha + 1)(\beta + 1)}{1-x^2} \right] u = 0, \quad (3)$$

where

$$u = u(x) = (1-x)^{(\alpha+1)/2}(1+x)^{(\beta+1)/2}P_n^{(\alpha, \beta)}(x), \quad (4)$$

and

$$\frac{d^2u}{d\theta^2} + \left[ \frac{\frac{1}{4} - \alpha^2}{4 \sin^2(\frac{1}{2}\theta)} + \frac{\frac{1}{4} - \beta^2}{4 \cos^2(\frac{1}{2}\theta)} + \left( n + \frac{\alpha + \beta + 1}{2} \right)^2 \right] u = 0, \quad (5)$$

where

$$u = u(\theta) = \sin^{\alpha+1/2}(\frac{1}{2}\theta) \cos^{\beta+1/2}(\frac{1}{2}\theta) P_n^{(\alpha, \beta)}(\cos \theta). \quad (6)$$

**Jacobi Differential Equation (Calculus of Variations)**

$$\frac{d}{dx} \Omega_{\eta'} - \Omega_{\eta} = \frac{d}{dx} (f_{y'y} \eta + f_{y'y'} \eta') - (f_{yy} \eta + f_{yy'} \eta') = 0,$$

where

$$\Omega(x, \eta, \eta') \equiv \frac{1}{2} (f_{yy} \eta^2 + 2f_{yy'} \eta \eta' + f_{y'y} \eta'^2).$$

This equations arises in the CALCULUS OF VARIATIONS.

**Jacobi Elliptic Functions**

The Jacobi elliptic functions are standard forms of ELLIPTIC FUNCTIONS. The three basic functions are denoted  $\text{cn}(u, k)$ ,  $\text{dn}(u, k)$ , and  $\text{sn}(u, k)$ , where  $k$  is known as the MODULUS. In terms of THETA FUNCTIONS,

$$\text{sn}(u, k) = \frac{\vartheta_3}{\vartheta_4} \frac{\vartheta_1(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \quad (1)$$

$$\text{cn}(u, k) = \frac{\vartheta_4}{\vartheta_2} \frac{\vartheta_2(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \quad (2)$$

$$\text{dn}(u, k) = \frac{\vartheta_4}{\vartheta_3} \frac{\vartheta_3(u\vartheta_3^{-2})}{\vartheta_4(u\vartheta_3^{-2})} \quad (3)$$

(Whittaker and Watson 1990, p. 492), where  $\vartheta_i \equiv \vartheta_i(0)$  (Whittaker and Watson 1990, p. 464). Ratios of Jacobi elliptic functions are denoted by combining the first letter of the NUMERATOR elliptic function with the first of the DENOMINATOR elliptic function. The multiplicative inverses of the elliptic functions are denoted by reversing the order of the two letters. These combinations give a total of 12 functions:  $\text{cd}$ ,  $\text{cn}$ ,  $\text{cs}$ ,  $\text{dc}$ ,  $\text{dn}$ ,  $\text{ds}$ ,  $\text{nc}$ ,  $\text{nd}$ ,  $\text{ns}$ ,  $\text{sc}$ ,  $\text{sd}$ , and  $\text{sn}$ . The AMPLITUDE  $\phi$  is defined in terms of  $\text{sn } u$  by

$$y = \sin \phi = \text{sn}(u, k). \quad (4)$$

The  $k$  argument is often suppressed for brevity so, for example,  $\text{sn}(u, k)$  can be written  $\text{sn } u$ .

The Jacobi elliptic functions are periodic in  $K(k)$  and  $K'(k)$  as

$$\text{sn}(u + 2mK + 2niK', k) = (-1)^m \text{sn}(u, k) \quad (5)$$

$$\text{cn}(u + 2mK + 2niK', k) = (-1)^{m+n} \text{cn}(u, k) \quad (6)$$

$$\text{dn}(u + 2mK + 2niK', k) = (-1)^n \text{dn}(u, k), \quad (7)$$

where  $K(k)$  is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND,  $K'(k) \equiv K(k')$ , and  $k' \equiv \sqrt{1-k^2}$  (Whittaker and Watson 1990, p. 503).

The  $\text{cn } x$ ,  $\text{dn } x$ , and  $\text{sn } x$  functions may also be defined as solutions to the differential equations

$$\frac{d^2y}{dx^2} = -(1+k^2)y + 2k^2y^3 \quad (8)$$

$$\frac{d^2y}{dx^2} = -(1-2k^2)y - 2k^2y^3 \quad (9)$$

$$\frac{d^2y}{dx^2} = (2-k^2)y - 2y^3. \quad (10)$$

The standard Jacobi elliptic functions satisfy the identities

$$\text{sn}^2 u + \text{cn}^2 u = 1 \quad (11)$$

$$k^2 \text{sn}^2 u + \text{dn}^2 u = 1 \quad (12)$$

$$k^2 \text{cn}^2 u + k'^2 = \text{dn}^2 u \quad (13)$$

$$\text{cn}^2 u + k'^2 \text{sn}^2 u = \text{dn}^2 u. \quad (14)$$

Special values are

$$\operatorname{cn}(0) = 1 \quad (15)$$

$$\operatorname{dn}(0) = 1 \quad (16)$$

$$\operatorname{cn}(K) = 0 \quad (17)$$

$$\operatorname{dn}(K) = k' \equiv \sqrt{1 - k^2}, \quad (18)$$

$$\operatorname{sn}(K) = 1, \quad (19)$$

where  $K = K(k)$  is a complete ELLIPTIC INTEGRAL OF THE FIRST KIND and  $k'$  is the complementary MODULUS (Whittaker and Watson 1990, pp. 498–499).

In terms of integrals,

$$u = \int_0^{\operatorname{sn} u} (1 - t^2)^{-1/2} (1 - k^2 t^2)^{-1/2} dt \quad (20)$$

$$= \int_{\operatorname{ns} u}^{\infty} (t^2 - 1)^{-1/2} (t^2 - k'^2)^{-1/2} dt \quad (21)$$

$$= \int_{\operatorname{cn} u}^1 (1 - t^2)^{-1/2} (k'^2 + k^2 t^2)^{-1/2} dt \quad (22)$$

$$= \int_1^{\operatorname{nc} u} (t^2 - 1)^{-1/2} (k'^2 t^2 + k^2)^{-1/2} dt \quad (23)$$

$$= \int_{\operatorname{dn} u}^1 (1 - t^2)^{-1/2} (t^2 - k'^2)^{-1/2} dt \quad (24)$$

$$= \int_1^{\operatorname{nd} u} (t^2 - 1)^{-1/2} (1 - k'^2 t^2)^{-1/2} dt \quad (25)$$

$$= \int_0^U (1 + t^2)^{-1/2} (1 + k'^2 t^2)^{-1/2} dt \quad (26)$$

$$= \int_{\operatorname{cs} u}^{\infty} (t^2 + 1)^{-1/2} (t^2 + k'^2)^{-1/2} dt \quad (27)$$

$$= \int_0^{\operatorname{sd} u} (1 - k'^2 t^2)^{-1/2} (1 + k^2 t^2)^{-1/2} dt \quad (28)$$

$$= \int_{\operatorname{ds} u}^{\infty} (t^2 - k'^2)^{-1/2} (t^2 + k^2)^{-1/2} dt \quad (29)$$

$$= \int_1^{\operatorname{cd} u} (1 - t^2)^{-1/2} (1 - k^2 t^2)^{-1/2} dt \quad (30)$$

$$= \int_{\operatorname{dc} u}^1 (t^2 - 1)^{-1/2} (t^2 - k^2)^{-1/2} dt \quad (31)$$

(Whittaker and Watson 1990, p. 494).

Jacobi elliptic functions addition formulas include

$$\operatorname{sn}(u + v) = \frac{\operatorname{sn} u \operatorname{cn} v \operatorname{dn} v + \operatorname{sn} v \operatorname{cn} u \operatorname{dn} u}{1 - k^2 \operatorname{sn}^2 u \operatorname{sn}^2 v} \quad (32)$$

$$\operatorname{cn}(u + v) = \frac{\operatorname{cn} u \operatorname{cn} v - \operatorname{sn} u \operatorname{sn} v \operatorname{dn} u \operatorname{dn} v}{1 - k^2 \operatorname{sn}^2 u \operatorname{sn}^2 v} \quad (33)$$

$$\operatorname{dn}(u + v) = \frac{\operatorname{dn} u \operatorname{dn} v - k^2 \operatorname{sn} u \operatorname{sn} v \operatorname{cn} u \operatorname{cn} v}{1 - k^2 \operatorname{sn}^2 u \operatorname{sn}^2 v}. \quad (34)$$

Extended to integral periods,

$$\operatorname{sn}(u + K) = \frac{\operatorname{cn} u}{\operatorname{dn} u} \quad (35)$$

$$\operatorname{cn}(u + K) = -\frac{k' \operatorname{sn} u}{\operatorname{dn} u} \quad (36)$$

$$\operatorname{dn}(u + K) = \frac{k'}{\operatorname{dn} u} \quad (37)$$

$$\operatorname{sn}(u + 2K) = -\operatorname{sn} u \quad (38)$$

$$\operatorname{cn}(u + 2K) = -\operatorname{cn} u \quad (39)$$

$$\operatorname{dn}(u + 2K) = \operatorname{dn} u \quad (40)$$

For COMPLEX arguments,

$$\operatorname{sn}(u + iv) = \frac{\operatorname{sn}(u, k) \operatorname{dn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')} + \frac{i \operatorname{cn}(u, k) \operatorname{dn}(u, k) \operatorname{sn}(v, k') \operatorname{cn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')} \quad (41)$$

$$\operatorname{cn}(u + iv) = \frac{\operatorname{cn}(u, k) \operatorname{cn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')} - \frac{i \operatorname{sn}(u, k) \operatorname{dn}(u, k) \operatorname{sn}(v, k') \operatorname{dn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')} \quad (42)$$

$$\operatorname{dn}(u + iv) = \frac{\operatorname{dn}(u, k) \operatorname{cn}(v, k') \operatorname{dn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')} - \frac{ik^2 \operatorname{sn}(u, k) \operatorname{cn}(u, k) \operatorname{sn}(v, k')}{1 - \operatorname{dn}^2(u, k) \operatorname{sn}^2(v, k')}. \quad (43)$$

DERIVATIVES of the Jacobi elliptic functions include

$$\frac{d \operatorname{sn} u}{du} = \operatorname{cn} u \operatorname{dn} u \quad (44)$$

$$\frac{d \operatorname{cn} u}{du} = \operatorname{sn} u \operatorname{dn} u \quad (45)$$

$$\frac{d \operatorname{dn} u}{du} = -k^2 \operatorname{sn} u \operatorname{cn} u. \quad (46)$$

Double-period formulas involving the Jacobi elliptic functions include

$$\operatorname{sn}(2u) = \frac{2 \operatorname{sn} u \operatorname{cn} u \operatorname{dn} u}{1 - k^2 \operatorname{sn}^4 u} \quad (47)$$

$$\operatorname{cn}(2u) = \frac{1 - 2 \operatorname{sn}^2 u + k^2 \operatorname{sn}^4 u}{1 - k^2 \operatorname{sn}^4 u} \quad (48)$$

$$\operatorname{dn}(2u) = \frac{1 - 2k^2 \operatorname{sn}^2 u + k^2 \operatorname{sn}^4 u}{1 - k^2 \operatorname{sn}^4 u}. \quad (49)$$

Half-period formulas involving the Jacobi elliptic functions include

$$\operatorname{sn}(\tfrac{1}{2}K) = \frac{1}{\sqrt{1 + k'}} \quad (50)$$

$$\operatorname{cn}(\tfrac{1}{2}K) = \sqrt{\frac{k'}{1 + k'}} \quad (51)$$

$$\operatorname{dn}(\tfrac{1}{2}K) = \sqrt{k'}. \quad (52)$$

Squared formulas include

$$\operatorname{sn}^2 u = \frac{1 - \operatorname{cn}(2u)}{1 + \operatorname{dn}(2u)} \quad (53)$$

$$\operatorname{cn}^2 u = \frac{\operatorname{dn}(2u) + \operatorname{cn}(2u)}{1 + \operatorname{dn}(2u)} \quad (54)$$

$$\operatorname{dn}^2 u = \frac{\operatorname{dn}(2u) + \operatorname{cn}(2u)}{1 + \operatorname{cn}(2u)}. \quad (55)$$

see JACOBI POLYNOMIAL

### Jacobi Function of the Second Kind

$$Q_n^{(\alpha, \beta)}(x) = 2^{-n-1} (x-1)^{-\alpha} (x+1)^{-\beta} \times \int_{-1}^1 (1-t)^{n+\alpha} (1+t)^{n+\beta} (x-t)^{-n-1} dt.$$

In the exceptional case  $n = 0$ ,  $\alpha + \beta + 1 = 0$ , a nonconstant solution is given by

$$Q^{(\alpha)}(x) = \ln(x+1) + \pi^{-1} \sin(\pi\alpha) (x-1)^{-\alpha} (x+1)^{-\beta} \times \int_{-1}^1 \frac{(1-t)^\alpha (1+t)^\beta}{x-t} \ln(1+t) dt.$$

### Jacobi-Gauss Quadrature

Also called JACOBI QUADRATURE or MEHLER QUADRATURE. A GAUSSIAN QUADRATURE over the interval  $[-1, 1]$  with WEIGHTING FUNCTION  $W(x) = (1-x)^\alpha (1+x)^\beta$ . The ABSCISSAS for quadrature order  $n$  are given by the roots of the JACOBI POLYNOMIALS  $P_n^{(\alpha, \beta)}(x)$ . The weights are

$$w_i = - \frac{A_{n+1} \gamma_n}{A_n P_n^{(\alpha, \beta)'}(x_i) P_{n+1}^{(\alpha, \beta)}(x_i)} = \frac{A_n}{A_{n-1}} \frac{\gamma_{n-1}}{P_{n-1}^{(\alpha, \beta)}(x_i) P_n^{(\alpha, \beta)'}(x_i)}, \quad (1)$$

where  $A_n$  is the COEFFICIENT of  $x^n$  in  $P_n^{(\alpha, \beta)}(x)$ . For JACOBI POLYNOMIALS,

$$A_n = \frac{\Gamma(2n + \alpha + \beta + 1)}{2^n n! \Gamma(n + \alpha + \beta + 1)}, \quad (2)$$

where  $\Gamma(z)$  is a GAMMA FUNCTION. Additionally,

$$\gamma_n = \frac{1}{2^{2n} (n!)^2} \frac{2^{2n+\alpha+\beta+1} n!}{2n + \alpha + \beta + 1} \times \frac{\Gamma(n + \alpha + 1) \Gamma(n + \beta + 1)}{\Gamma(n + \alpha + \beta + 1)}, \quad (3)$$

so

$$w_i = \frac{2n + \alpha + \beta + 2}{n + \alpha + \beta + 1} \frac{\Gamma(n + \alpha + 1) \Gamma(n + \beta + 1)}{\Gamma(n + \alpha + \beta + 1)} \times \frac{2^{2n+\alpha+\beta+1} n!}{V_n'(x_i) V_{n+1}(x_i)} = \frac{\Gamma(n + \alpha + 1) \Gamma(n + \beta + 1)}{\Gamma(n + \alpha + \beta + 1)} \frac{2^{2n+\alpha+\beta+1} n!}{(1 - x_i^2) [V_n'(x_i)]^2}, \quad (4)$$

$$(5)$$

where

$$V_m \equiv P_m^{(\alpha, \beta)}(x) \frac{2^n n!}{(-1)^n}. \quad (6)$$

The error term is

$$E_n = \frac{\Gamma(n + \alpha + 1) \Gamma(n + \beta + 1) \Gamma(n + \alpha + \beta + 1)}{(2n + \alpha + \beta + 1) [\Gamma(2n + \alpha + \beta + 1)]^2} \times \frac{2^{2n+\alpha+\beta+1} n!}{(2n)!} f^{(2n)}(\xi) \quad (7)$$

(Hildebrand 1959).

**Jacobi Identities**

"The" Jacobi identity is a relationship

$$[A, [B, C]] + [B, [C, A]] + [C, [A, B]] = 0, \quad (1)$$

between three elements  $A$ ,  $B$ , and  $C$ , where  $[A, B]$  is the COMMUTATOR. The elements of a LIE GROUP satisfy this identity.

Relationships between the  $Q$ -FUNCTIONS  $Q_i$  are also known as Jacobi identities:

$$Q_1 Q_2 Q_3 = 1, \quad (2)$$

equivalent to the JACOBI TRIPLE PRODUCT (Borwein and Borwein 1987, p. 65) and

$$Q_2^8 = 16qQ_1^8 + Q_3^8, \quad (3)$$

where

$$q \equiv e^{-\pi K'(k)/K(k)}, \quad (4)$$

$K = K(k)$  is the complete ELLIPTIC INTEGRAL OF THE FIRST KIND, and  $K'(k) = K(k') = K(\sqrt{1-k^2})$ . Using WEBER FUNCTIONS

$$f_1 = q^{-1/24} Q_3 \quad (5)$$

$$f_2 = 2^{1/2} q^{1/12} Q_1 \quad (6)$$

$$f = q^{-1/24} Q_2, \quad (7)$$

(5) and (6) become

$$f_1 f_2 f = \sqrt{2} \quad (8)$$

$$f^8 = f_1^8 + f_2^8 \quad (9)$$

(Borwein and Borwein 1987, p. 69).

**Jacobi Matrix**

see JACOBI ROTATION MATRIX, JACOBIAN

**Jacobi Method**

A method of diagonalizing MATRICES using JACOBI ROTATION MATRICES. It consists of a sequence of ORTHOGONAL SIMILARITY TRANSFORMATIONS, each of which eliminates one off-diagonal element.

see also JACOBI ALGORITHM, JACOBI ROTATION MATRIX

**References**

Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Jacobi Transformation of a Symmetric Matrix." §11.1 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 456-462, 1992.

**Jacobi Polynomial**

Also known as the HYPERGEOMETRIC POLYNOMIALS, they occur in the study of ROTATION GROUPS and in the solution to the equations of motion of the symmetric top. They are solutions to the JACOBI DIFFERENTIAL EQUATION. Plugging

$$y = \sum_{\nu=0}^{\infty} a_{\nu} (x-1)^{\nu} \quad (1)$$

into the differential equation gives the RECURRENCE RELATION

$$[\gamma - \nu(\nu + \alpha + \beta + 1)]a_{\nu} - 2(\nu + 1)(\nu + \alpha + 1)a_{\nu+1} = 0 \quad (2)$$

for  $\nu = 0, 1, \dots$ , where

$$\gamma \equiv n(n + \alpha + \beta + 1). \quad (3)$$

Solving the RECURRENCE RELATION gives

$$P_n^{(\alpha, \beta)}(x) = \frac{(-1)^n}{2^n n!} (1-x)^{-\alpha} (1+x)^{-\beta} \times \frac{d^n}{dx^n} [(1-x)^{\alpha+n} (1+x)^{\beta+n}] \quad (4)$$

for  $\alpha, \beta > -1$ . They form a complete orthogonal system in the interval  $[-1, 1]$  with respect to the weighting function

$$w_n(x) = (1-x)^{\alpha} (1+x)^{\beta}, \quad (5)$$

and are normalized according to

$$P_n^{(\alpha, \beta)}(1) = \binom{n + \alpha}{n}, \quad (6)$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. Jacobi polynomials can also be written

$$P_n^{(\alpha, \beta)} = \frac{\Gamma(2n + \alpha + \beta + 1)}{n! \Gamma(n + \alpha + \beta + 1)} \times G_n(\alpha + \beta + 1, \beta + 1, \frac{1}{2}(x+1)), \quad (7)$$

where  $\Gamma(z)$  is the GAMMA FUNCTION and

$$G_n(p, q, x) \equiv \frac{n! \Gamma(n+p)}{\Gamma(2n+p)} P_n^{(p-q, q-1)}(2x-1). \quad (8)$$

Jacobi polynomials are ORTHOGONAL satisfying

$$\begin{aligned} \int_{-1}^1 P_m^{(\alpha, \beta)} P_n^{(\alpha, \beta)} (1-x)^\alpha (1+x)^\beta dx \\ = \frac{2^{\alpha+\beta+1}}{2n+\alpha+\beta+1} \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{n!\Gamma(n+\alpha+\beta+1)} \delta_{mn}. \end{aligned} \quad (9)$$

The COEFFICIENT of the term  $x^n$  in  $P_n^{(\alpha, \beta)}(x)$  is given by

$$A_n = \frac{\Gamma(2n+\alpha+\beta+1)}{2^n n! \Gamma(n+\alpha+\beta+1)}. \quad (10)$$

They satisfy the RECURRENCE RELATION

$$\begin{aligned} 2(n+1)(n+\alpha+\beta+1)(2n+\alpha+\beta)P_{n+1}^{(\alpha, \beta)}(x) \\ = [(2n+\alpha+\beta+1)(\alpha^2-\beta^2) + (2n+\alpha+\beta)_3 x] P_n^{(\alpha, \beta)}(x) \\ - 2(n+\alpha)(n+\beta)(2n+\alpha+\beta+2)P_{n-1}^{(\alpha, \beta)}(x), \end{aligned} \quad (11)$$

where  $(m)_n$  is the RISING FACTORIAL

$$(m)_n \equiv m(m+1) \cdots (m+n-1) = \frac{(m+n-1)!}{(m-1)!}. \quad (12)$$

The DERIVATIVE is given by

$$\frac{d}{dx} [P_n^{(\alpha, \beta)}(x)] = \frac{1}{2} (n+\alpha+\beta+1) P_{n-1}^{(\alpha+1, \beta+1)}(x). \quad (13)$$

The ORTHOGONAL POLYNOMIALS with WEIGHTING FUNCTION  $(b-x)^\alpha (x-a)^\beta$  on the CLOSED INTERVAL  $[a, b]$  can be expressed in the form

$$[\text{const.}] P_n^{(\alpha, \beta)} \left( 2 \frac{x-a}{b-a} - 1 \right) \quad (14)$$

(Szegő 1975, p. 58).

Special cases with  $\alpha = \beta$  are

$$\begin{aligned} P_{2\nu}^{(\alpha, \alpha)}(x) &= \frac{\Gamma(2\nu+\alpha+1)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+1)} P_\nu^{(\alpha, -1/2)}(2x^2-1) \\ &= (-1)^\nu \frac{\Gamma(2\nu+\alpha+1)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+1)} P_\nu^{(-1/2, \alpha)}(1-2x^2) \end{aligned} \quad (15)$$

$$\begin{aligned} P_{2\nu+1}^{(\alpha, \alpha)}(x) &= \frac{\Gamma(2\nu+\alpha+2)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+2)} x P_\nu^{(\alpha, 1/2)}(2x^2-1) \\ &= (-1)^\nu \frac{\Gamma(2\nu+\alpha+2)\Gamma(\nu+1)}{\Gamma(\nu+\alpha+1)\Gamma(2\nu+2)} x P_\nu^{(1/2, \alpha)}(1-2x^2). \end{aligned} \quad (16)$$

Further identities are

$$\begin{aligned} P_n^{(\alpha+1, \beta)}(x) &= \frac{2}{2n+\alpha+\beta+2} \\ &\times \frac{(n+\alpha+1)P_n^{(\alpha, \beta)}(x) - (n+1)P_{n+1}^{(\alpha, \beta)}(x)}{1-x} \end{aligned} \quad (17)$$

$$\begin{aligned} P_n^{(\alpha, \beta+1)}(x) &= \frac{2}{2n+\alpha+\beta+2} \\ &\times \frac{(n+\beta+1)P_n^{(\alpha, \beta)}(x) + (n+1)P_{n+1}^{(\alpha, \beta)}(x)}{1+x} \end{aligned} \quad (18)$$

$$\begin{aligned} \sum_{\nu=0}^n \frac{2\nu+\alpha+\beta+1}{2^{\alpha+\beta+1}} \frac{\Gamma(\nu+1)\Gamma(\nu+\alpha+\beta+1)}{\Gamma(\nu+\alpha+1)\Gamma(\nu+\beta+1)} \\ \times P_\nu^{(\alpha, \beta)}(x) Q_\nu^{(\alpha, \beta)}(y) \\ = \frac{1}{2} \frac{(y-1)^{-\alpha}(y+1)^{-\beta}}{y-x} + \frac{2^{-\alpha-\beta}}{2n+\alpha+\beta+2} \\ \times \frac{\Gamma(n+2)\Gamma(n+\alpha+\beta+2)}{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)} \\ \times \frac{P_{n+1}^{(\alpha, \beta)}(x) Q_n^{(\alpha, \beta)}(y) - P_n^{(\alpha, \beta)}(x) Q_{n+1}^{(\alpha, \beta)}(y)}{x-y} \end{aligned} \quad (19)$$

(Szegő 1975, p. 79).

The KERNEL POLYNOMIAL is

$$\begin{aligned} K_n^{(\alpha, \beta)}(x, y) &= \frac{2^{-\alpha-\beta}}{2n+\alpha+\beta+2} \\ &\times \frac{\Gamma(n+2)\Gamma(n+\alpha+\beta+2)}{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)} \\ &\times \frac{P_{n+1}^{(\alpha, \beta)}(x) P_n^{(\alpha, \beta)}(y) - P_n^{(\alpha, \beta)}(x) P_{n+1}^{(\alpha, \beta)}(y)}{x-y} \end{aligned} \quad (20)$$

(Szegő 1975, p. 71).

The DISCRIMINANT is

$$\begin{aligned} D_n^{(\alpha, \beta)} &= 2^{-n(n-1)} \prod_{\nu=1}^n \nu^{\nu-2n+2} (\nu+\alpha)^{\nu-1} (\nu+\beta)^{\nu-1} \\ &\times (n+\nu+\alpha+\beta)^{n-\nu} \end{aligned} \quad (21)$$

(Szegő 1975, p. 143).

For  $\alpha = \beta = 0$ ,  $P_n^{(0,0)}(x)$  reduces to a LEGENDRE POLYNOMIAL. The GEGENBAUER POLYNOMIAL

$$G_n(p, q, x) = \frac{n! \Gamma(n+p)}{\Gamma(2n+p)} P_n^{(p-q, q-1)}(2x-1) \quad (22)$$

and CHEBYSHEV POLYNOMIAL OF THE FIRST KIND can also be viewed as special cases of the Jacobi POLYNOMIALS. In terms of the HYPERGEOMETRIC FUNCTION,

$$\begin{aligned} P_n^{(\alpha, \beta)}(x) &= \binom{n+\alpha}{n} \\ &\times {}_2F_1(-n, n+\alpha+\beta; \alpha+1; \tfrac{1}{2}(1-x)) \end{aligned} \quad (23)$$

$$\begin{aligned} P_n^{(\alpha, \beta)}(x) &= \binom{n+\alpha}{n} \left( \frac{x+1}{2} \right)^2 \\ &\times {}_2F_1\left(-n, -n-\beta; \alpha+1; \frac{x-1}{x+1}\right). \end{aligned} \quad (24)$$

Let  $N_1$  be the number of zeros in  $x \in (-1, 1)$ ,  $N_2$  the number of zeros in  $x \in (-\infty, -1)$ , and  $N_3$  the number of zeros in  $x \in (1, \infty)$ . Define Klein's symbol

$$E(u) = \begin{cases} 0 & \text{if } u \leq 0 \\ \lfloor u \rfloor & \text{if } u \text{ positive and nonintegral} \\ u - 1 & \text{if } u = 1, 2, \dots, \end{cases} \quad (25)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION, and

$$X(\alpha, \beta) = E\left[\frac{1}{2}(|2n + \alpha + \beta + 1| - |\alpha| - |\beta| + 1)\right] \quad (26)$$

$$Y(\alpha, \beta) = E\left[\frac{1}{2}(-|2n + \alpha + \beta + 1| + |\alpha| - |\beta| + 1)\right] \quad (27)$$

$$Z(\alpha, \beta) = E\left[\frac{1}{2}(-|2n + \alpha + \beta + 1| - |\alpha| + |\beta| + 1)\right]. \quad (28)$$

If the cases  $\alpha = -1, -2, \dots, -n$ ,  $\beta = -1, -2, \dots, -n$ , and  $n + \alpha + \beta = -1, -2, \dots, -n$  are excluded, then the number of zeros of  $P_n^{(\alpha, \beta)}$  in the respective intervals are

$$N_1(\alpha, \beta) = \begin{cases} 2 \left\lfloor \frac{1}{2}(X + 1) \right\rfloor & \text{for } (-1)^n \binom{n+\alpha}{n} \binom{n+\beta}{n} > 0 \\ 2 \left\lfloor \frac{1}{2}X \right\rfloor + 1 & \text{for } (-1)^n \binom{n+\alpha}{n} \binom{n+\beta}{n} < 0 \end{cases} \quad (29)$$

$$N_2(\alpha, \beta) = \begin{cases} 2 \left\lfloor \frac{1}{2}(Y + 1) \right\rfloor & \text{for } \binom{2n+\alpha+\beta}{n} \binom{n+\beta}{n} > 0 \\ 2 \left\lfloor \frac{1}{2}Y \right\rfloor + 1 & \text{for } \binom{2n+\alpha+\beta}{n} \binom{n+\beta}{n} < 0 \end{cases} \quad (30)$$

$$N_3(\alpha, \beta) = \begin{cases} 2 \left\lfloor \frac{1}{2}(Z + 1) \right\rfloor & \text{for } \binom{2n+\alpha+\beta}{n} \binom{n+\alpha}{n} > 0 \\ 2 \left\lfloor \frac{1}{2}Z \right\rfloor + 1 & \text{for } \binom{2n+\alpha+\beta}{n} \binom{n+\alpha}{n} < 0 \end{cases} \quad (31)$$

(Szegő 1975, pp. 144–146).

The first few POLYNOMIALS are

$$\begin{aligned} P_0^{(\alpha, \beta)}(x) &= 1 \\ P_1^{(\alpha, \beta)}(x) &= \frac{1}{2}[2(\alpha + 1) + (\alpha + \beta + 2)(x - 1)] \\ P_2^{(\alpha, \beta)}(x) &= \frac{1}{8}[4(\alpha + 1)_2 + 4(\alpha + \beta + 3)(\alpha + 2)(x - 1) \\ &\quad + (\alpha + \beta + 2)_2(x - 1)^2], \end{aligned}$$

where  $(m)_n$  is a RISING FACTORIAL. See Abramowitz and Stegun (1972, pp. 782–793) and Szegő (1975, Ch. 4) for additional identities.

## Jacobi Quadrature

see JACOBI-GAUSS QUADRATURE

## Jacobi Rotation Matrix

A MATRIX used in the JACOBI TRANSFORMATION method of diagonalizing MATRICES. It contains  $\cos \phi$  in  $p$  rows and columns and  $\sin \phi$  in  $q$  rows and columns,

$$P_{pq} \equiv \begin{bmatrix} 1 & & & & & & 0 \\ & \ddots & & & & & \\ & & \cos \phi & \cdots & 0 & \cdots & \sin \phi \\ & & 0 & \cdots & 1 & \cdots & 0 \\ & & \sin \phi & \cdots & 0 & \cdots & \cos \phi \\ & & & & & & \\ & & & & & & \\ 0 & & & & & & 1 \end{bmatrix}.$$

see also JACOBI TRANSFORMATION

## References

- Press, W. H.; Flannery, B. P.; Teukolsky, S. A.; and Vetterling, W. T. "Jacobi Transformation of a Symmetric Matrix." §11.1 in *Numerical Recipes in FORTRAN: The Art of Scientific Computing*, 2nd ed. Cambridge, England: Cambridge University Press, pp. 456–462, 1992.

## Jacobi Symbol

The product of LEGENDRE SYMBOLS  $(n/p_i)$  for each of the PRIME factors  $p_i$  such that  $m = \prod_i p_i$ , denoted  $(n/m)$ . When  $m$  is a PRIME, the Jacobi symbol reduces to the LEGENDRE SYMBOL. The Jacobi symbol satisfies the same rules as the LEGENDRE SYMBOL.

$$(n/m)(n/m') = (n/(mm')) \quad (1)$$

$$(n/m)(n'/m) = ((nn')/m) \quad (2)$$

$$(n^2/m) = (n/m^2) = 1 \quad \text{if } (m, n) = 1 \quad (3)$$

$$(n/m) = (n'/m) \quad \text{if } n \equiv n' \pmod{m} \quad (4)$$

$$(-1/m) = (-1)^{(m-1)/2} = \begin{cases} 1 & \text{for } m \equiv 1 \pmod{4} \\ -1 & \text{for } m \equiv -1 \pmod{4} \end{cases} \quad (5)$$

$$(2/m) = (-1)^{(m^2-1)/8} = \begin{cases} 1 & \text{for } m \equiv \pm 1 \pmod{8} \\ -1 & \text{for } m \equiv \pm 3 \pmod{8} \end{cases} \quad (6)$$

$$(n/m) = \begin{cases} (m/n) & \text{for } m \text{ or } n \equiv 1 \pmod{4} \\ -(m/n) & \text{for } m, n \equiv 3 \pmod{4}. \end{cases} \quad (7)$$

Written another way, for  $m$  and  $n$  RELATIVELY PRIME ODD INTEGERS with  $n \geq 3$ ,

$$(m/n) = (-1)^{(m-1)(n-1)/4} (n/m). \quad (8)$$

The Jacobi symbol is not defined if  $m \leq 0$  or  $m$  is EVEN.

Bach and Shallit (1996) show how to compute the Jacobi symbol in terms of the SIMPLE CONTINUED FRACTION of a RATIONAL NUMBER  $a/b$ .

see also KRONECKER SYMBOL

**Jacobi Tensor**

$$J_{\nu\alpha\beta}^{\mu} = J_{\nu\beta\alpha}^{\mu} \equiv \frac{1}{2}(R_{\alpha\nu\beta}^{\mu} + R_{\beta\nu\alpha}^{\mu}),$$

where  $R$  is the RIEMANN TENSOR.

see also RIEMANN TENSOR

**Jacobi's Theorem**

Let  $M_r$  be an  $r$ -rowed MINOR of the  $n$ th order DETERMINANT  $|A|$  associated with an  $n \times n$  MATRIX  $A = a_{ij}$  in which the rows  $i_1, i_2, \dots, i_r$  are represented with columns  $k_1, k_2, \dots, k_r$ . Define the complementary minor to  $M_r$  as the  $(n - k)$ -rowed MINOR obtained from  $|A|$  by deleting all the rows and columns associated with  $M_r$  and the signed complementary minor  $M^{(r)}$  to  $M_r$  to be

$$M^{(r)} = (-1)^{i_1+i_2+\dots+i_r+k_1+k_2+\dots+k_r} \times [\text{complementary minor to } M_r].$$

Let the MATRIX of cofactors be given by

$$\Delta = \begin{vmatrix} A_{11} & A_{12} & \cdots & A_{1n} \\ A_{21} & A_{22} & \cdots & A_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ A_{n1} & A_{n2} & \cdots & A_{nn} \end{vmatrix},$$

with  $M_r$  and  $M'_r$  the corresponding  $r$ -rowed minors of  $|A|$  and  $\Delta$ , then it is true that

$$M'_r = |A|^{r-1} M^{(r)}.$$

**Jacobi Theta Function**

see THETA FUNCTION

**Jacobi Transformation**

see JACOBI METHOD

**Jacobi Triple Product**

The Jacobi triple product is the beautiful identity

$$\prod_{n=1}^{\infty} (1 - x^{2n})(1 + x^{2n-1}z^2) \left(1 + \frac{x^{2n-1}}{z^2}\right) = \sum_{m=-\infty}^{\infty} x^{m^2} z^{2m}. \quad (1)$$

In terms of the  $Q$ -FUNCTIONS, (1) is written

$$Q_1 Q_2 Q_3 = 1, \quad (2)$$

which is one of the two JACOBI IDENTITIES. For the special case of  $z = 1$ , (1) becomes

$$\begin{aligned} \varphi(x) &\equiv G(1) = \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 (1 - x^{2n}) \\ &= \sum_{m=-\infty}^{\infty} x^{m^2} = 1 + 2 \sum_{m=0}^{\infty} x^{m^2}, \end{aligned} \quad (3)$$

where  $\varphi(x)$  is the one-variable RAMANUJAN THETA FUNCTION.

To prove the identity, define the function

$$\begin{aligned} F(z) &\equiv \prod_{n=1}^{\infty} (1 + x^{2n-1}z^2) \left(1 + \frac{x^{2n-1}}{z^2}\right) \\ &= (1 + xz^2) \left(1 + \frac{x}{z^2}\right) (1 + x^3z^2) \left(1 + \frac{x^3}{z^2}\right) \\ &\quad \times (1 + x^5z^2) \left(1 + \frac{x^5}{z^2}\right) \cdots \end{aligned} \quad (4)$$

Then

$$\begin{aligned} F(xz) &= (1 + x^3z^2) \left(1 + \frac{1}{xz^2}\right) (1 + x^5z^2) \left(1 + \frac{x}{z^2}\right) \\ &\quad (1 + x^7z^2) \left(1 + \frac{x^3}{z^2}\right) \cdots \end{aligned} \quad (5)$$

Taking (5)  $\div$  (4),

$$\begin{aligned} \frac{F(xz)}{F(z)} &= \left(1 + \frac{1}{xz^2}\right) \left(\frac{1}{1 + xz^2}\right) \\ &= \frac{xz^2 + 1}{xz^2} \frac{1}{1 + xz^2} = \frac{1}{xz^2}, \end{aligned} \quad (6)$$

which yields the fundamental relation

$$xz^2 F(xz) = F(z). \quad (7)$$

Now define

$$G(z) \equiv F(z) \prod_{n=1}^{\infty} (1 - x^{2n}) \quad (8)$$

$$G(xz) = F(xz) \prod_{n=1}^{\infty} (1 - x^{2n}). \quad (9)$$

Using (7), (9) becomes

$$G(xz) = \frac{F(z)}{xz^2} \prod_{n=1}^{\infty} (1 - x^{2n}) = \frac{G(z)}{xz^2}, \quad (10)$$

so

$$G(z) = xz^2 G(xz). \quad (11)$$

Expand  $G$  in a LAURENT SERIES. Since  $G$  is an EVEN FUNCTION, the LAURENT SERIES contains only even terms.

$$G(z) = \sum_{m=-\infty}^{\infty} a_m z^{2m}. \quad (12)$$

Equation (11) then requires that

$$\begin{aligned} \sum_{m=-\infty}^{\infty} a_m z^{2m} &= xz^2 \sum_{m=-\infty}^{\infty} a_m (xz)^{2m} \\ &= \sum_{m=-\infty}^{\infty} a_m x^{2m+1} z^{2m+2}. \end{aligned} \quad (13)$$

This can be re-indexed with  $m' \equiv m - 1$  on the left side of (13)

$$\sum_{m=-\infty}^{\infty} a_m z^{2m} = \sum_{m=-\infty}^{\infty} a_m x^{2m-1} z^{2m}, \quad (14)$$

which provides a RECURRENCE RELATION

$$a_m = a_{m-1} x^{2m-1}, \quad (15)$$

so

$$a_1 = a_0 x \quad (16)$$

$$a_2 = a_1 x^3 = a_0 x^{3+1} = a_0 x^4 = a_0 x^{2^2} \quad (17)$$

$$a_3 = a_2 x^5 = a_0 x^{5+4} = a_0 x^9 = a_0 x^{3^2}. \quad (18)$$

The exponent grows greater by  $(2m-1)$  for each increase in  $m$  of 1. It is given by

$$\sum_{n=1}^m (2n-1) = 2 \frac{m(m+1)}{2} - m = m^2. \quad (19)$$

Therefore,

$$a_m = a_0 x^{m^2}. \quad (20)$$

This means that

$$G(z) = a_0 \sum_{m=-\infty}^{\infty} x^{m^2} z^{2m}. \quad (21)$$

The COEFFICIENT  $a_0$  must be determined by going back to (4) and (8) and letting  $z = 1$ . Then

$$\begin{aligned} F(1) &= \prod_{n=1}^{\infty} (1 + x^{2n-1})(1 + x^{2n-1}) \\ &= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 \end{aligned} \quad (22)$$

$$\begin{aligned} G(1) &= F(1) \prod_{n=1}^{\infty} (1 - x^{2n}) \\ &= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 \prod_{n=1}^{\infty} (1 - x^{2n}) \\ &= \prod_{n=1}^{\infty} (1 + x^{2n-1})^2 (1 - x^{2n}), \end{aligned} \quad (23)$$

since multiplication is ASSOCIATIVE. It is clear from this expression that the  $a_0$  term must be 1, because all other terms will contain higher POWERS of  $x$ . Therefore,

$$a_0 = 1, \quad (24)$$

so we have the Jacobi triple product,

$$\begin{aligned} G(z) &= \prod_{n=1}^{\infty} (1 - x^{2n})(1 + x^{2n-1} z^2) \left(1 + \frac{x^{2n-1}}{z^2}\right) \\ &= \sum_{m=-\infty}^{\infty} x^{m^2} z^{2m}. \end{aligned} \quad (25)$$

### Jacobian

Given a set  $\mathbf{y} = \mathbf{f}(\mathbf{x})$  of  $n$  equations in  $n$  variables  $x_1, \dots, x_n$ , written explicitly as

$$\mathbf{y} \equiv \begin{bmatrix} f_1 \\ f_2 \\ \vdots \\ f_n \end{bmatrix}, \quad (1)$$

or more explicitly as

$$\begin{cases} y_1 = f_1(x_1, \dots, x_n) \\ \vdots \\ y_n = f_n(x_1, \dots, x_n), \end{cases} \quad (2)$$

the Jacobian matrix, sometimes simply called "the Jacobian" (Simon and Blume 1994) is defined by

$$J(x_1, x_2, x_3) = \begin{bmatrix} \frac{\partial y_1}{\partial x_1} & \dots & \frac{\partial y_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial y_n}{\partial x_1} & \dots & \frac{\partial y_n}{\partial x_n} \end{bmatrix}. \quad (3)$$

The DETERMINANT of  $J$  is the JACOBIAN DETERMINANT (confusingly, often called "the Jacobian" as well) and is denoted

$$J = \left| \frac{\partial(y_1, \dots, y_n)}{\partial(x_1, \dots, x_n)} \right|. \quad (4)$$

Taking the differential

$$d\mathbf{y} = \mathbf{y}_x d\mathbf{x} \quad (5)$$

shows that  $J$  is the DETERMINANT of the MATRIX  $\mathbf{y}_x$ , and therefore gives the ratios of  $n$ -D volumes (CONTENTS) in  $y$  and  $x$ ,

$$dy_1 \cdots dy_n = \left| \frac{\partial(y_1, \dots, y_n)}{\partial(x_1, \dots, x_n)} \right| dx_1 \cdots dx_n. \quad (6)$$

The concept of the Jacobian can also be applied to  $n$  functions in more than  $n$  variables. For example, considering  $f(u, v, w)$  and  $g(u, v, w)$ , the Jacobians

$$\frac{\partial(f, g)}{\partial(u, v)} = \begin{vmatrix} f_u & f_v \\ g_u & g_v \end{vmatrix} \quad (7)$$

$$\frac{\partial(f, g)}{\partial(u, w)} = \begin{vmatrix} f_u & f_w \\ g_u & g_w \end{vmatrix} \quad (8)$$

can be defined (Kaplan 1984, p. 99).

For the case of  $n = 3$  variables, the Jacobian takes the special form

$$Jf(x_1, x_2, x_3) \equiv \left| \frac{\partial \mathbf{y}}{\partial x_1} \cdot \frac{\partial \mathbf{y}}{\partial x_2} \times \frac{\partial \mathbf{y}}{\partial x_3} \right|, \quad (9)$$

where  $\mathbf{a} \cdot \mathbf{b}$  is the DOT PRODUCT and  $\mathbf{b} \times \mathbf{c}$  is the CROSS PRODUCT, which can be expanded to give

$$\left| \frac{\partial(y_1, y_2, y_3)}{\partial(x_1, x_2, x_3)} \right| = \begin{vmatrix} \frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \frac{\partial y_1}{\partial x_3} \\ \frac{\partial y_2}{\partial x_1} & \frac{\partial y_2}{\partial x_2} & \frac{\partial y_2}{\partial x_3} \\ \frac{\partial y_3}{\partial x_1} & \frac{\partial y_3}{\partial x_2} & \frac{\partial y_3}{\partial x_3} \end{vmatrix}. \quad (10)$$

### Jacobian Conjecture

If  $\det[F'(x)] = 1$  for a POLYNOMIAL mapping  $F$  (where  $\det$  is the DETERMINANT), then  $F$  is BIJECTIVE with POLYNOMIAL inverse.

### Jacobian Curve

The Jacobian of a linear net of curves of order  $n$  is a curve of order  $3(n - 1)$ . It passes through all points common to all curves of the net. It is the LOCUS of points where the curves of the net touch one another and of singular points of the curve.

### Jacobsthal-Lucas Number

see JACOBSTHAL NUMBER

### Jacobsthal-Lucas Polynomial

see JACOBSTHAL POLYNOMIAL

### Jacobsthal Number

The Jacobsthal numbers are the numbers obtained by the  $U_n$ s in the LUCAS SEQUENCE with  $P = 1$  and  $Q = -2$ , corresponding to  $a = 2$  and  $b = -1$ . They and the Jacobsthal-Lucas numbers (the  $V_n$ s) satisfy the RECURRENCE RELATION

$$J_n = J_{n-1} + 2J_{n-2}. \quad (1)$$

The Jacobsthal numbers satisfy  $J_0 = 0$  and  $J_1 = 1$  and are 0, 1, 1, 3, 5, 11, 21, 43, 85, 171, 341, ... (Sloane's A001045). The Jacobsthal-Lucas numbers satisfy  $j_0 = 2$  and  $j_1 = 1$  and are 2, 1, 5, 7, 17, 31, 65, 127, 257, 511, 1025, ... (Sloane's A014551). The properties of these numbers are summarized in Horadam (1996). They are given by the closed form expressions

$$J_n = \sum_{r=0}^{\lfloor (n-1)/2 \rfloor} \binom{n-1-r}{r} 2^r \quad (2)$$

$$j_n = \sum_{r=0}^{\lfloor n/2 \rfloor} \frac{n}{n-r} \binom{n-r}{r} 2^r, \quad (3)$$

where  $\lfloor x \rfloor$  is the FLOOR FUNCTION and  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT. The Binet forms are

$$J_n = \frac{1}{3}(a^n - b^n) = \frac{1}{3}[2^n - (-1)^n] \quad (4)$$

$$j_n = a^n + b^n = 2^n + (-1)^n. \quad (5)$$

The GENERATING FUNCTIONS are

$$\sum_{i=1}^{\infty} J_i x^{i-1} = (1 - x - 2x^2)^{-1} \quad (6)$$

$$\sum_{i=1}^{\infty} j_i x^{i-1} = (1 + 4x)(1 - x - 2x^2)^{-1}. \quad (7)$$

The SIMSON FORMULAS are

$$J_{n+1}J_{n-1} - J_n^2 = (-1)^n 2^{n-1} \quad (8)$$

$$j_{n+1}j_{n-1} - j_n^2 = 9(-1)^{n-1} 2^{n-1} = -9(J_{n+1}J_{n-1} - J_n^2). \quad (9)$$

Summation FORMULAS include

$$\sum_{i=2}^n J_i = \frac{1}{2}(J_{n+2} - 3) \quad (10)$$

$$\sum_{i=1}^n j_i = \frac{1}{2}(j_{n+2} - 5). \quad (11)$$

Interrelationships are

$$j_n J_n = J_{2n} \quad (12)$$

$$j_n = J_{n+1} + 2J_{n-1} \quad (13)$$

$$9J_n = j_{n+1} + 2j_{n-1} \quad (14)$$

$$j_{n+1} + j_n = 3(J_{n+1} + J_n) = 3 \cdot 2^n \quad (15)$$

$$j_{n+1} - j_n = 3(J_{n+1} - J_n) + 4(-1)^{n+1} = 2^n + 2(-1)^{n+1} \quad (16)$$

$$j_{n+1} - 2j_n = 3(2J_n - J_{n+1}) = 3(-1)^{n+1} \quad (17)$$

$$2j_{n+1} + j_{n-1} = 3(2J_{n+1} + J_{n-1}) + 6(-1)^{n+1} \quad (18)$$

$$j_{n+r} + j_{n-r} = 3(J_{n+r} + J_{n-r}) + 4(-1)^{n-r} \quad (19)$$

$$= 2^{n-r}(2^{2r} + 1) + 2(-1)^{n-r} \quad (20)$$

$$j_{n+r} - j_{n-r} = 3(J_{n+r} - J_{n-r}) = 2^{n-r}(2^{2r} - 1) \quad (21)$$

$$j_n = 3J_n + 2(-1)^n \quad (22)$$

$$3J_n + j_n = 2^{n+1} \quad (23)$$

$$J_n + j_n = 2J_{n+1} \quad (24)$$

$$j_{n+2}j_{n-2} - j_n^2 = -9(J_{n+2}J_{n-2} - J_n^2) = 9(-1)^n 2^{n-2} \quad (25)$$

$$J_m j_n + J_n j_m = 2J_{m+n} \quad (26)$$

$$j_m j_n + 9J_m J_n = 2j_{m+n} \quad (27)$$

$$j_n^2 + 9J_n^2 = 2j_{2n} \quad (28)$$

$$J_m j_n - J_n j_m = (-1)^n 2^{n+1} J_{m-n} \quad (29)$$

$$j_m j_n - 9J_m J_n = (-1)^n 2^{n+1} j_{m-n} \quad (30)$$

$$j_n^2 - 9J_n^2 = (-1)^n 2^{n+2} \quad (31)$$

(Horadam 1996).

### Jacobsthal Polynomial

The Jacobsthal polynomials are the POLYNOMIALS obtained by setting  $p(x) = 1$  and  $q(x) = 2x$  in the LUCAS POLYNOMIAL SEQUENCE. The first few Jacobsthal polynomials are

$$J_1(x) = 1$$

$$J_2(x) = 1$$

$$J_3(x) = 1 + 2x$$

$$J_4(x) = 1 + 4x$$

$$J_5(x) = 4x^2 + 6x + 1,$$

and the first few Jacobsthal-Lucas polynomials are

$$\begin{aligned}j_1(x) &= 1 \\j_2(x) &= 4x + 1 \\j_3(x) &= 6x + 1 \\j_4(x) &= 8x^2 + 8x + 1 \\j_5(x) &= 20x^2 + 10x + 1.\end{aligned}$$

Jacobsthal and Jacobsthal-Lucas polynomials satisfy

$$J_n(1) = J_n$$

$$j_n(1) = j_n$$

where  $J_n$  is a JACOBSTHAL NUMBER and  $j_n$  is a JACOBSTHAL-LUCAS NUMBER.

### Janko Groups

The SPORADIC GROUPS  $J_1$ ,  $J_2$ ,  $J_3$  and  $J_4$ . The Janko group  $J_2$  is also known as the HALL-JANKO GROUP.

### Japanese Triangulation Theorem

Let a convex CYCLIC POLYGON be TRIANGULATED in any manner, and draw the INCIRCLE to each TRIANGLE so constructed. Then the sum of the INRADIUS is a constant independent of the TRIANGULATION chosen. This theorem can be proved using CARNOT'S THEOREM. It is also true that if the sum of INRADIUS does not depend on the TRIANGULATION of a POLYGON, then the POLYGON is CYCLIC.

see also CARNOT'S THEOREM, CYCLIC POLYGON, INCIRCLE, INRADIUS, TRIANGULATION

### References

Honsberger, R. *Mathematical Gems III*. Washington, DC: Math. Assoc. Amer., pp. 24-26, 1985.

### Jarnick's Inequality

Given a CONVEX plane region with AREA  $A$  and PERIMETER  $p$ , then

$$|N - A| < p,$$

where  $N$  is the number of enclosed LATTICE POINTS.

see also LATTICE POINT, NOSARZEWSKA'S INEQUALITY

### Jeep Problem

Maximize the distance a jeep can penetrate into the desert using a given quantity of fuel. The jeep is allowed to go forward, unload some fuel, and then return to its base using the fuel remaining in its tank. At its base, it may refuel and set out again. When it reaches fuel it has previously stored, it may then use it to partially fill its tank. This problem is also called the EXPLORATION PROBLEM (Ball and Coxeter 1987).

Given  $n + f$  (with  $0 \leq f < 1$ ) drums of fuel at the edge of the desert and a jeep capable of holding one drum (and storing fuel in containers along the way), the maximum one-way distance which can be traveled (assuming the jeep travels one unit of distance per drum of fuel expended) is

$$\begin{aligned}d &= \frac{f}{2n+1} + \sum_{i=1}^n \frac{1}{2i-1} \\&= \frac{f}{2n+1} + \frac{1}{2}[\gamma + 2\ln 2 + \psi_0(\frac{1}{2} + n)],\end{aligned}$$

where  $\gamma$  is the EULER-MASCHERONI CONSTANT and  $\psi_n(z)$  the POLYGAMMA FUNCTION.

For example, the farthest a jeep with  $n = 1$  drum can travel is obviously 1 unit. However, with  $n = 2$  drums of gas, the maximum distance is achieved by filling up the jeep's tank with the first drum, traveling  $1/3$  of a unit, storing  $1/3$  of a drum of fuel there, and then returning to base with the remaining  $1/3$  of a tank. At the base, the tank is filled with the second drum. The jeep then travels  $1/3$  of a unit (expending  $1/3$  of a drum of fuel), refills the tank using the  $1/3$  of a drum of fuel stored there, and continues an additional 1 unit of distance on a full tank, giving a total distance of  $4/3$ . The solutions for  $n = 1, 2, \dots$  drums are 1,  $4/3$ ,  $23/15$ ,  $176/105$ ,  $563/315$ ,  $\dots$ , which can also be written as  $a(n)/b(n)$ , where

$$\begin{aligned}a(n) &= \left(\frac{1}{1} + \frac{1}{3} + \dots + \frac{1}{2n-1}\right) \text{LCM}(1, 3, 5, \dots, 2n-1) \\b(n) &= \text{LCM}(1, 3, 5, \dots, 2n-1)\end{aligned}$$

(Sloane's A025550 and A025547).

### Jensen's Formula

$$\int_0^{2\pi} \ln |z + e^{i\theta}| d\theta = 2\pi \ln^+ |z|,$$

where

$$\ln^+ \equiv \max(0, \ln x)$$

and  $\ln x$  is the NATURAL LOGARITHM.

### Jensen's Inequality

For a REAL CONTINUOUS CONCAVE FUNCTION

$$\frac{\sum f(x_i)}{n} < f\left(\frac{\sum x_i}{n}\right)$$

if  $f$  is concave down,

$$\frac{\sum f(x_i)}{n} \geq f\left(\frac{\sum x_i}{n}\right)$$

if  $f$  is concave up, and

$$\frac{\sum f(x_i)}{n} = f\left(\frac{\sum x_i}{n}\right)$$

IFF  $x_1 = x_2 = \dots = x_n$ . A special case is

$$\sqrt[n]{x_1 x_2 \dots x_n} \leq \frac{x_1 + x_2 + \dots + x_n}{n},$$

with equality IFF  $x_1 = x_2 = \dots = x_n$ .

### Jerk

The jerk  $j$  is defined as the time DERIVATIVE of the VECTOR ACCELERATION  $\mathbf{a}$ ,

$$\mathbf{j} \equiv \frac{d\mathbf{a}}{dt}.$$

see also ACCELERATION, VELOCITY

**Jinc Function**

The jinc function is defined as

$$\text{jinc}(x) \equiv \frac{J_1(x)}{x},$$

where  $J_1(x)$  is a BESSEL FUNCTION OF THE FIRST KIND, and satisfies  $\lim_{x \rightarrow 0} \text{jinc}(x) = 1/2$ . The DERIVATIVE of the jinc function is given by

$$\text{jinc}'(x) = -\frac{J_2(x)}{x}.$$

The function is sometimes normalized by multiplying by a factor of 2 so that  $\text{jinc}(0) = 1$  (Siegman 1986, p. 729).

**Johnson Solid**

The Johnson solids are the CONVEX POLYHEDRA having regular faces (with the exception of the completely regular PLATONIC SOLIDS, the "SEMIREGULAR" ARCHIMEDEAN SOLIDS, and the two infinite families of PRISMS and ANTIPRISMS). There are 28 simple (i.e., cannot be dissected into two other regular-faced polyhedra by a plane) regular-faced polyhedra in addition to the PRISMS and ANTIPRISMS (Zalgaller 1969), and Johnson (1966) proposed and Zalgaller (1969) proved that there exist exactly 92 Johnson solids in all.

A database of solids and VERTEX NETS of these solids is maintained on the Bell Laboratories Netlib server, but a few errors exist in several entries. A concatenated and corrected version of the files is given by Weisstein, together with *Mathematica*® (Wolfram Research, Champaign, IL) code to display the solids and nets. The following table summarizes the names of the Johnson solids and gives their images and nets.

### Johnson's Theorem

Let three equal CIRCLES with centers  $C_1$ ,  $C_2$ , and  $C_3$  intersect in a single point  $O$  and intersect pairwise in the points  $P$ ,  $Q$ , and  $R$ . Then the CIRCUMCIRCLE  $J$  of  $\triangle PQR$  (the so-called JOHNSON CIRCLE) is congruent to the original three.

### Join (Graph)

Let  $x$  and  $y$  be distinct nodes of  $G$  which are not joined by an EDGE. Then the graph  $G/xy$  which is formed by adding the EDGE  $(x, y)$  to  $G$  is called a join of  $G$ .

### Join (Spaces)

Let  $X$  and  $Y$  be TOPOLOGICAL SPACES. Then their join is the factor space

$$X * Y = (X \times Y \times I) / \sim,$$

where  $\sim$  is the EQUIVALENCE RELATION

$$(x, y, t) \sim (x', y', t') \Leftrightarrow \begin{cases} t = t' = 0 \text{ and } x = x' \\ \text{or} \\ t = t' = 1 \text{ and } y = y'. \end{cases}$$

### Joint Distribution Function

A joint distribution function is a DISTRIBUTION FUNCTION in two variables defined by

$$D(x, y) \equiv P(X \leq x, Y \leq y) \quad (1)$$

$$D_x(x) \equiv D(x, \infty) \quad (2)$$

$$D_y(y) \equiv D(\infty, y) \quad (3)$$

so that the joint probability function

$$P[(x, y) \in C] = \iint_{(x, y) \in C} P(x, y) dx dy \quad (4)$$

$$P(x \in A, y \in B) = \int_B \int_A P(x, y) dx dy \quad (5)$$

$$\begin{aligned} P(x, y) &= P\{x \in (-\infty, x], y \in (-\infty, y]\} \\ &= \int_{-\infty}^x \int_{-\infty}^y P(x, y) dx dy \end{aligned} \quad (6)$$

$$\begin{aligned} P(a \leq x \leq a + da, b \leq y \leq b + db) \\ = \int_b^{b+db} \int_a^{a+da} P(x, y) dx dy \approx P(a, b) da db. \end{aligned} \quad (7)$$

A multiple distribution function is of the form

$$D(a_1, \dots, a_n) \equiv P(x_1 \leq a_1, \dots, x_n \leq a_n). \quad (8)$$

see also DISTRIBUTION FUNCTION

### Joint Probability Density Function

see JOINT DISTRIBUTION FUNCTION

### Joint Theorem

see GAUSSIAN JOINT VARIABLE THEOREM

### Jonah Formula

A formula for the generalized CATALAN NUMBER  $p d_{qi}$ . The general formula is

$$\binom{n-q}{k-1} = \sum_{i=1}^k p d_{qi} \binom{n-pi}{k-i},$$

where  $\binom{n}{k}$  is a BINOMIAL COEFFICIENT, although Jonah's original formula corresponded to  $p = 2$ ,  $q = 0$  (Hilton and Pederson 1991).

Hilton, P. and Pederson, J. "Catalan Numbers, Their Generalization, and Their Uses." *Math. Intel.* **13**, 64-75, 1991.

### Jones Polynomial

The second KNOT POLYNOMIAL discovered. Unlike the first-discovered ALEXANDER POLYNOMIAL, the Jones polynomial can sometimes distinguish handedness (as can its more powerful generalization, the HOMFLY POLYNOMIAL). Jones polynomials are LAURENT POLYNOMIALS in  $t$  assigned to an  $\mathbb{R}^3$  KNOT. The Jones polynomials are denoted  $V_L(t)$  for LINKS,  $V_K(t)$  for KNOTS, and normalized so that

$$V_{\text{unknot}}(t) = 1. \quad (1)$$

For example, the Jones polynomial of the TREFOIL KNOT is given by

$$V_{\text{trefoil}}(t) = t + t^3 - t^4. \quad (2)$$

If a LINK has an ODD number of components, then  $V_L$  is a LAURENT POLYNOMIAL over the INTEGERS; if the number of components is EVEN,  $V_L(t)$  is  $t^{1/2}$  times a LAURENT POLYNOMIAL. The Jones polynomial of a KNOT SUM  $L_1 \# L_2$  satisfies

$$V_{L_1 \# L_2} = (V_{L_1})(V_{L_2}). \quad (3)$$

The SKEIN RELATIONSHIP for under- and overcrossings is

$$t^{-1}V_{L_+} - tV_{L_-} = (t^{1/2} - t^{-1/2})V_{L_0}. \quad (4)$$

Combined with the link sum relationship, this allows Jones polynomials to be built up from simple knots and links to more complicated ones.

Some interesting identities from Jones (1985) follow. For any LINK  $L$ ,

$$V_L(-1) = \Delta_L(-1), \quad (5)$$

where  $\Delta_L$  is the ALEXANDER POLYNOMIAL, and

$$V_L(1) = (-2)^{p-1}, \quad (6)$$

where  $p$  is the number of components of  $L$ . For any KNOT  $K$ ,

$$V_K(e^{2\pi i/3}) = 1 \quad (7)$$

and

$$\frac{d}{dt} V_K(1) = 0. \quad (8)$$

Let  $K^*$  denote the MIRROR IMAGE of a KNOT  $K$ . Then

$$V_{K^*}(t) = V_K(t^{-1}). \quad (9)$$

For example, the right-hand and left-hand TREFOIL KNOTS have polynomials

$$V_{\text{trefoil}}(t) = t + t^3 - t^4 \quad (10)$$

$$V_{\text{trefoil}^*}(t) = t^{-1} + t^{-3} - t^{-4}. \quad (11)$$

Jones defined a simplified trace invariant for knots by

$$W_K(t) = \frac{1 - V_K(t)}{(1 - t^3)(1 - t)}. \quad (12)$$

The ARF INVARIANT of  $W_K$  is given by

$$\text{Arf}(K) = W_K(i) \quad (13)$$

(Jones 1985), where  $i$  is  $\sqrt{-1}$ . A table of the  $W$  polynomials is given by Jones (1985) for knots of up to eight crossings, and by Jones (1987) for knots of up to 10 crossings. (Note that in these papers, an additional polynomial which Jones calls  $V$  is also tabulated, but it is not the conventionally defined Jones polynomial.)

Jones polynomials were subsequently generalized to the two-variable HOMFLY POLYNOMIALS, the relationship being

$$V(t) = P(a = t, x = t^{1/2} - t^{-1/2}) \quad (14)$$

$$V(t) = P(\ell = it, m = i(t^{-1/2} - t^{1/2})). \quad (15)$$

They are related to the KAUFFMAN POLYNOMIAL  $F$  by

$$V(t) = F(-t^{-3/4}, t^{-1/4} + t^{1/4}). \quad (16)$$

Jones (1987) gives a table of BRAID WORDS and  $W$  polynomials for knots up to 10 crossings. Jones polynomials for KNOTS up to nine crossings are given in Adams (1994) and for oriented links up to nine crossings by Doll and Hoste (1991). All PRIME KNOTS with 10 or fewer crossings have distinct Jones polynomials. It is not known if there is a nontrivial knot with Jones polynomial 1. The Jones polynomial of an  $(m, n)$ -TORUS KNOT is

$$\frac{t^{(m-1)(n-1)/2}(1 - t^{m+1} - t^{n+1} + t^{m+n})}{1 - t^2}. \quad (17)$$

Let  $k$  be one component of an oriented LINK  $L$ . Now form a new oriented LINK  $L^*$  by reversing the orientation of  $k$ . Then

$$V_{L^*} = t^{-3\lambda} V(L),$$

where  $V$  is the Jones polynomial and  $\lambda$  is the LINKING NUMBER of  $k$  and  $L - k$ . No such result is known for HOMFLY POLYNOMIALS (Lickorish and Millett 1988).

Birman and Lin (1993) showed that substituting the POWER SERIES for  $e^x$  as the variable in the Jones polynomial yields a POWER SERIES whose COEFFICIENTS are VASSILIEV POLYNOMIALS.

Let  $L$  be an oriented connected LINK projection of  $n$  crossings, then

$$n \geq \text{span } V(L), \quad (18)$$

with equality if  $L$  is ALTERNATING and has no REMOVABLE CROSSING (Lickorish and Millett 1988).

There exist distinct KNOTS with the same Jones polynomial. Examples include  $(05_{001}, 10_{132})$ ,  $(08_{008}, 10_{129})$ ,  $(08_{016}, 10_{156})$ ,  $(10_{025}, 10_{056})$ ,  $(10_{022}, 10_{035})$ ,  $(10_{041}, 10_{094})$ ,  $(10_{043}, 10_{091})$ ,  $(10_{059}, 10_{106})$ ,  $(10_{060}, 10_{083})$ ,  $(10_{071}, 10_{104})$ ,  $(10_{073}, 10_{086})$ ,  $(10_{081}, 10_{109})$ , and  $(10_{137}, 10_{155})$  (Jones 1987). Incidentally, the first four of these also have the same HOMFLY POLYNOMIAL.

Witten (1989) gave a heuristic definition in terms of a topological quantum field theory, and Sawin (1996) showed that the “quantum group”  $U_q(sl_2)$  gives rise to the Jones polynomial.

### Jonquière’s Function

see POLYGAMMA FUNCTION

### Jordan Algebra

A nonassociative algebra with the product of elements  $A$  and  $B$  defined by the ANTICOMMUTATOR  $\{A, B\} = AB + BA$ .

see also ANTICOMMUTATOR

### Jordan Curve

A Jordan curve is a plane curve which is topologically equivalent to (a HOMEOMORPHIC image of) the UNIT CIRCLE.

It is not known if every Jordan curve contains all four VERTICES of some SQUARE, but it has been proven true for “sufficiently smooth” curves and closed convex curves (Schnirelmann). For every TRIANGLE  $T$  and Jordan curve  $J$ ,  $J$  has an INSCRIBED TRIANGLE similar to  $T$ .

see also JORDAN CURVE THEOREM, UNIT CIRCLE

### Jordan Curve Theorem

If  $J$  is a simple closed curve in  $\mathbb{R}^2$ , then  $\mathbb{R}^2 - J$  has two components (an “inside” and “outside”), with  $J$  the BOUNDARY of each.

see also JORDAN CURVE, SCHÖNFLIES THEOREM

### Jordan-Hölder Theorem

The composition quotient groups belonging to two COMPOSITION SERIES of a FINITE GROUP  $G$  are, apart from their sequence, ISOMORPHIC in pairs. In other words, if

$$I \subset H_s \subset \dots \subset H_2 \subset H_1 \subset G$$

is one COMPOSITION SERIES and

$$I \subset K_t \subset \dots \subset K_2 \subset K_1 \subset G$$

is another, then  $t = s$ , and corresponding to any composition quotient group  $K_j/K_{j+1}$ , there is a composition quotient group  $H_i/H_{i+1}$  such that

$$\frac{K_j}{K_{j+1}} = \frac{H_i}{H_{i+1}}.$$

This theorem was proven in 1869–1889.

#### Jordan's Inequality

For  $0 \leq x \leq \pi/2$ ,

$$\frac{2}{\pi}x \leq \sin x \leq x.$$

#### References

Yuefeng, F. "Jordan's Inequality." *Math. Mag.* **69**, 126, 1996.

#### Jordan's Lemma

Jordan's lemma shows the value of the INTEGRAL

$$I \equiv \int_{-\infty}^{\infty} f(x)e^{iax} dx \quad (1)$$

along the REAL AXIS is 0 for "nice" functions which satisfy  $\lim_{R \rightarrow \infty} |f(Re^{i\theta})| = 0$ . This is established using a CONTOUR INTEGRAL  $I_R$  which satisfies

$$\lim_{R \rightarrow \infty} |I_R| \leq \frac{\pi}{a} \lim_{R \rightarrow \infty} \epsilon = 0. \quad (2)$$

To derive the lemma, write

$$x \equiv Re^{i\theta} = R(\cos \theta + i \sin \theta) \quad (3)$$

$$dx = iRe^{i\theta} d\theta \quad (4)$$

and define the CONTOUR INTEGRAL

$$I_R = \int_0^\pi f(Re^{i\theta})e^{iaR \cos \theta - aR \sin \theta} iRe^{i\theta} d\theta \quad (5)$$

Then

$$\begin{aligned} |I_R| &= R \int_0^\pi |f(Re^{i\theta})| |e^{iaR \cos \theta}| |e^{-aR \sin \theta}| |i| |e^{i\theta}| d\theta \\ &= R \int_0^\pi |f(Re^{i\theta})| e^{-aR \sin \theta} d\theta \\ &= 2R \int_0^{\pi/2} |f(Re^{i\theta})| e^{-aR \sin \theta} d\theta. \end{aligned} \quad (6)$$

Now, if  $\lim_{R \rightarrow \infty} |f(Re^{i\theta})| = 0$ , choose an  $\epsilon$  such that  $|f(Re^{i\theta})| \leq \epsilon$ , so

$$|I_R| \leq 2R\epsilon \int_0^{\pi/2} e^{-aR \sin \theta} d\theta. \quad (7)$$

But, for  $\theta \in [0, \pi/2]$ ,

$$\frac{2}{\pi}\theta \leq \sin \theta, \quad (8)$$

so

$$\begin{aligned} |I_R| &\leq 2R\epsilon \int_0^{\pi/2} e^{-2aR\theta/\pi} d\theta \\ &= 2\epsilon R \frac{1 - e^{-aR}}{\frac{2aR}{\pi}} = \frac{\pi\epsilon}{a} (1 - e^{-aR}). \end{aligned} \quad (9)$$

As long as  $\lim_{R \rightarrow \infty} |f(z)| = 0$ , Jordan's lemma

$$\lim_{R \rightarrow \infty} |I_R| \leq \frac{\pi}{a} \lim_{R \rightarrow \infty} \epsilon = 0 \quad (10)$$

then follows.

#### Jordan Measure

Let the set  $M$  correspond to a bounded, NONNEGATIVE function  $f$  on an interval  $0 \leq f(x) \leq c$  for  $x \in [a, b]$ . The Jordan measure, when it exists, is the common value of the outer and inner Jordan measures of  $M$ .

The outer Jordan measure is the greatest lower bound of the areas of the covering of  $M$ , consisting of finite unions of RECTANGLES. The inner Jordan measure of  $M$  is the difference between the AREA  $c(a - b)$  of the RECTANGLE  $S$  with base  $[a, b]$  and height  $c$ , and the outer measure of the complement of  $M$  in  $S$ .

#### Jordan Polygon

see SIMPLE POLYGON

**Josephus Problem**

Given a group of  $n$  men arranged in a CIRCLE under the edict that every  $m$ th man will be executed going around the CIRCLE until only one remains, find the position  $L(n, m)$  in which you should stand in order to be the last survivor (Ball and Coxeter 1987). The original problem consisted of a CIRCLE of 41 men with every third man killed ( $n = 41$ ,  $m = 3$ ). In order for the lives of the last two men to be spared, they must be placed at positions 31 (last) and 16 (second-to-last).

The following array gives the original position of the last survivor out of a group of  $n = 1, 2, \dots$ , if every  $m$ th man is killed:

1									
2	1								
3	3	2							
4	1	1	2						
5	3	4	1	2					
6	5	1	5	1	4				
7	7	4	2	6	3	5			
8	1	7	6	3	1	4	4		
9	3	1	1	8	7	2	3	8	
10	5	4	5	3	3	9	1	7	8

(Sloane's A032434). The survivor for  $m = 2$  can be given analytically by

$$L(n, 2) = 1 + 2n - 2^{1+\lfloor \lg n \rfloor},$$

where  $\lfloor n \rfloor$  is the FLOOR FUNCTION and LG is the LOG-ARITHM to base 2. The first few solutions are therefore 1, 1, 3, 1, 3, 5, 7, 1, 3, 5, 7, 9, 11, 13, 15, 1, ... (Sloane's A006257).

Mott-Smith (1954) discusses a card game called "Out and Under" in which cards at the top of a deck are alternately discarded and placed at the bottom. This is a Josephus problem with parameter  $m = 2$ , and Mott-Smith hints at the above closed-form solution.

The original position of the second-to-last survivor is given in the following table for  $n = 2, 3, \dots$ :

1	1								
2	1	1							
3	1	1	2						
4	3	2	1	2					
5	1	1	5	1	4				
6	3	1	2	1	3	4			
7	1	4	6	3	1	3	4		
8	3	1	1	2	7	1	3	7	
9	5	4	5	3	3	8	1	6	4

(Sloane's A032435).

Another version of the problem considers a CIRCLE of two groups (say, "A" and "B") of 15 men each, with every ninth man cast overboard. To save all the members of the "A" group, the men must be placed at positions

1, 2, 3, 4, 10, 11, 13, 14, 15, 17, 20, 21, 25, 28, 29, giving the ordering

AAAABBBBBBAABAAABABBAABBBABBAAB

which can be remembered with the aid of the MNEMONIC "From numbers' aid and art, never will fame depart." Consider the vowels only, assign  $a = 1$ ,  $e = 2$ ,  $i = 3$ ,  $o = 4$ ,  $u = 5$ , and alternately add a number of letters corresponding to a vowel value, so 4A (o), 5B (u), 2A (e), etc. (Ball and Coxeter 1987).

If every tenth man is instead thrown overboard, the men from the "A" group must be placed in positions 1, 2, 4, 5, 6, 12, 13, 16, 17, 18, 19, 21, 25, 28, 29, giving the sequence

AABAAABBBBBBAABBAABAAABABBBABBAAB

which can be constructed using the MNEMONIC "Rex paphi cum gente bona dat signa serena" (Ball and Coxeter 1987).

**Jug**

see THREE JUG PROBLEM

**Jugendtraum**

Kronecker proved that all the Galois extensions of the RATIONALS  $\mathbb{Q}$  with ABELIAN Galois groups are SUB-FIELDS of cyclotomic fields  $\mathbb{Q}(\mu_n)$ , where  $\mu_n$  is the group of  $n$ th ROOTS OF UNITY. He then sought to find a similar function whose division values would generate the Abelian extensions of an arbitrary NUMBER FIELD. He discovered that the  $j$ -FUNCTION works for IMAGINARY quadratic number fields  $K$ , but the completion of this problem, known as Kronecker's Jugendtraum ("dream of youth"), for other fields remains one of the great unsolved problems in NUMBER THEORY.

## Julia Fractal

see JULIA SET

## Julia Set

Let  $R(z)$  be a rational function

$$R(z) \equiv \frac{P(z)}{Q(z)}, \quad (1)$$

where  $z \in \mathbb{C}^*$ ,  $\mathbb{C}^*$  is the RIEMANN SPHERE  $\mathbb{C} \cup \{\infty\}$ , and  $P$  and  $Q$  are POLYNOMIALS without common divisors. The "filled-in" Julia set  $J_R$  is the set of points  $z$  which do not approach infinity after  $R(z)$  is repeatedly applied. The true Julia set is the boundary of the filled-in set (the set of "exceptional points"). There are two types of Julia sets: connected sets and CANTOR SETS.

For a Julia set  $J_c$  with  $c \ll 1$ , the CAPACITY DIMENSION is

$$d_{\text{capacity}} = 1 + \frac{|c|^2}{4 \ln 2} + \mathcal{O}(|c|^3). \quad (2)$$

For small  $c$ ,  $J_c$  is also a JORDAN CURVE, although its points are not COMPUTABLE.

Quadratic Julia sets are generated by the quadratic mapping

$$z_{n+1} = z_n^2 + c \quad (3)$$

for fixed  $c$ . The special case  $c = -0.123 + 0.745i$  is called DOUADY'S RABBIT FRACTAL,  $c = -0.75$  is called the SAN MARCO FRACTAL, and  $c = -0.391 - 0.587i$  is the SIEGEL DISK FRACTAL. For every  $c$ , this transformation generates a FRACTAL. It is a CONFORMAL TRANSFORMATION, so angles are preserved. Let  $J$  be the JULIA SET, then  $x' \mapsto x$  leaves  $J$  invariant. If a point  $P$  is on  $J$ , then all its iterations are on  $J$ . The transformation has a two-valued inverse. If  $b = 0$  and  $y$  is started at 0, then the map is equivalent to the LOGISTIC MAP. The set of all points for which  $J$  is connected is known as the MANDELBROT SET.

## Jump

A point of DISCONTINUITY.

see also DISCONTINUITY, JUMP ANGLE, JUMPING CHAMPION

## Jump Angle

A GEODESIC TRIANGLE with oriented boundary yields a curve which is piecewise DIFFERENTIABLE. Furthermore, the TANGENT VECTOR varies continuously at all but the three corner points, where it changes suddenly. The angular difference of the tangent vectors at these corner points are called the jump angles.

see also ANGULAR DEFECT, GAUSS-BONNET FORMULA

## Jumping Champion

An integer  $n$  is called a JUMPING CHAMPION if  $n$  is the most frequently occurring difference between consecutive primes  $n \leq N$  for some  $N$  (Odlyzko *et al.*). This term was coined by J. H. Conway in 1993. There are occasionally several jumping champions in a range. Odlyzko *et al.* give a table of jumping champions for  $n \leq 1000$ , consisting mainly of 2, 4, and 6. 6 is the jumping champion up to about  $n \approx 1.74 \times 10^{35}$ , at which point 30 dominates. At  $n \approx 10^{425}$ , 210 becomes champion, and subsequent PRIMORIALS are conjectured to take over at larger and larger  $n$ . Erdős and Straus (1980) proved that the jumping champions tend to infinity under the assumption of a quantitative form of the  $k$ -tuples conjecture.

# K

## *k*-ary Divisor

Let a DIVISOR  $d$  of  $n$  be called a 1-ary divisor if  $d \perp n/d$ . Then  $d$  is called a  $k$ -ary divisor of  $n$ , written  $d|_k n$ , if the GREATEST COMMON  $(k-1)$ -ary divisor of  $d$  and  $(n/d)$  is 1.

In this notation,  $d|n$  is written  $d|_0 n$ , and  $d||n$  is written  $d|_1 n$ .  $p^x$  is an INFINARY DIVISOR of  $p^y$  (with  $y > 0$ ) if  $p^x|_{y-1} p^y$ .

see also DIVISOR, GREATEST COMMON DIVISOR, INFINARY DIVISOR

## References

Guy, R. K. *Unsolved Problems in Number Theory*, 2nd ed. New York: Springer-Verlag, p. 54, 1994.

## *k*-Chain

Any sum of a selection of  $\Pi_k$ s, where  $\Pi_k$  denotes a  $k$ -D POLYTOPE.

see also *k*-CIRCUIT

## *k*-Circuit

A  $k$ -CHAIN whose bounding  $(k-1)$ -CHAIN vanishes.

## *k*-Coloring

A  $k$ -coloring of a GRAPH  $G$  is an assignment of one of  $k$  possible colors to each vertex of  $G$  such that no two adjacent vertices receive the same color.

see also COLORING, EDGE-COLORING

## References

Saaty, T. L. and Kainen, P. C. *The Four-Color Problem: Assaults and Conquest*. New York: Dover, p. 13, 1986.

## *k*-Form

see DIFFERENTIAL *k*-FORM

## *K*-Function

An extension of the *K*-function

$$K(n+1) \equiv 0^0 1^1 2^2 3^3 \cdots n^n \quad (1)$$

defined by

$$K(z) = \frac{[\Gamma(z)]^z}{G(z)}. \quad (2)$$

Here,  $G(z)$  is the *G*-FUNCTION defined by

$$G(n+1) \equiv \frac{(n!)^n}{K(n+1)} = \begin{cases} 1 & \text{if } n = 0 \\ 0!1!2! \cdots (n-1)! & \text{if } n > 0. \end{cases} \quad (3)$$

The *K*-function is given by the integral

$$K(z) = (2\pi)^{-(z-1)/2} \exp \left[ \left( \frac{z}{2} \right) + \int_0^{z-1} \ln(t!) dt \right] \quad (4)$$

and the closed-form expression

$$K(z) = \exp[\zeta'(-1, z) - \zeta'(-1)], \quad (5)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION,  $\zeta'(z)$  its DERIVATIVE,  $\zeta(a, z)$  is the HURWITZ ZETA FUNCTION, and

$$\zeta'(a, z) \equiv \left[ \frac{d\zeta(s, z)}{ds} \right]_{s=a}. \quad (6)$$

$K(z)$  also has a STIRLING-like series

$$K(z+1) = (2^{1/3} \pi_1 z)^{1/12} z^{\binom{z+1}{2}} \times \exp \left( \frac{1}{4} z^2 + \frac{1}{12} - \frac{B_4}{2 \cdot 3 \cdot 4 z^2} - \frac{B_6}{4 \cdot 5 \cdot 6 z^4} - \cdots \right), \quad (7)$$

where

$$\pi_1 \equiv [K(\tfrac{1}{2})]^8 \quad (8)$$

$$= e^{-(\ln 2)/3 - 12\zeta'(-1)} \quad (9)$$

$$= 2^{2/3} \pi e^{\gamma - 1 - \zeta'(2)/\zeta(2)}, \quad (10)$$

and  $\gamma$  is the EULER-MASCHERONI CONSTANT (Gosper).

The first few values of  $K(n)$  for  $n = 2, 3, \dots$  are 1, 4, 108, 27648, 86400000, 4031078400000, ... (Sloane's A002109). These numbers are called HYPERFACTORIALS by Sloane and Plouffe (1995).

see also *G*-FUNCTION, GLAISHER-KINKELIN CONSTANT, HYPERFACTORIAL, STIRLING'S SERIES

Sloane, N. J. A. Sequence A002109/M3706 in "An On-Line Version of the Encyclopedia of Integer Sequences."

**K-Graph**

The GRAPH obtained by dividing a set of VERTICES  $\{1, \dots, n\}$  into  $k-1$  pairwise disjoint subsets with VERTICES of degree  $n_1, \dots, n_{k-1}$ , satisfying

$$n = n_1 + \dots + n_{k-1},$$

and with two VERTICES joined IFF they lie in distinct VERTEX sets. Such GRAPHS are denoted  $K_{n_1, \dots, n_k}$ .

see also BIPARTITE GRAPH, COMPLETE GRAPH, COMPLETE  $k$ -PARTITE GRAPH,  $k$ -PARTITE GRAPH

**k-Matrix**

A  $k$ -matrix is a kind of CUBE ROOT of the IDENTITY MATRIX defined by

$$k = \begin{bmatrix} 0 & 0 & -i \\ i & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}.$$

It satisfies

$$k^3 = I,$$

where  $I$  is the IDENTITY MATRIX.

see also CUBE ROOT, QUATERNION

**k-Partite Graph**

A  $k$ -partite graph is a GRAPH whose VERTICES can be partitioned into  $k$  disjoint sets so that no two vertices within the same set are adjacent.

see also COMPLETE  $k$ -PARTITE GRAPH,  $K$ -GRAPH

**References**

Saaty, T. L. and Kainen, P. C. *The Four-Color Problem: Assaults and Conquest*. New York: Dover, p. 12, 1986.

**k-Statistic**

An UNBIASED ESTIMATOR of the CUMULANTS  $\kappa_i$  of a DISTRIBUTION. The expectation values of the  $k$ -statistics are therefore given by the corresponding CUMULANTS

$$\langle k_1 \rangle = \kappa_1 \quad (1)$$

$$\langle k_2 \rangle = \kappa_2 \quad (2)$$

$$\langle k_3 \rangle = \kappa_3 \quad (3)$$

$$\langle k_4 \rangle = \kappa_4 \quad (4)$$

(Kenney and Keeping 1951, p. 189). For a sample of size,  $N$ , the first few  $k$ -statistics are given by

$$k_1 = m_1 \quad (5)$$

$$k_2 = \frac{N}{N-1} m_2 \quad (6)$$

$$k_3 = \frac{N^2}{(N-1)(N-2)} m_3 \quad (7)$$

$$k_4 = \frac{N^2[(N+1)m_4 - 3(N-1)m_2^2]}{(N-1)(N-2)(N-3)}, \quad (8)$$

where  $m_1$  is the sample MEAN,  $m_2$  is the sample VARIANCE, and  $m_i$  is the sample  $i$ th MOMENT about the MEAN (Kenney and Keeping 1951, pp. 109–110, 163–165, and 189; Kenney and Keeping 1962). These statistics are obtained from inverting the relationships

$$\langle m_1 \rangle = \mu \quad (9)$$

$$\langle m_2 \rangle = \frac{N-1}{N} \mu_2 \quad (10)$$

$$\langle m_2^2 \rangle = \frac{(N-1)[(N-1)\mu_4 + (N^2 - 2N + 3)\mu_2^2]}{N^3} \quad (11)$$

$$\langle m_3 \rangle = \frac{(N-1)(N-2)}{N^2} \mu_3 \quad (12)$$

$$\langle m_4 \rangle = \frac{(N-1)[(N^2 - 3N + 3)\mu_4 + 3(2N-3)\mu_2^2]}{N^3}. \quad (13)$$

The first moment (sample MEAN) is

$$m_1 \equiv \langle x \rangle = \frac{1}{N} \sum_{i=1}^N x_i, \quad (14)$$

and the expectation value is

$$\langle m_1 \rangle = \left\langle \frac{1}{N} \sum_{i=1}^N x_i \right\rangle = \mu. \quad (15)$$

The second MOMENT (sample STANDARD DEVIATION) is

$$\begin{aligned} m_2 &\equiv \langle (x - \mu)^2 \rangle = \langle x^2 \rangle - 2\mu \langle x \rangle + \mu^2 = \langle x^2 \rangle - \mu^2 \\ &= \frac{1}{N} \sum_{i=1}^N x_i^2 - \left( \frac{1}{N} \sum_{i=1}^N x_i \right)^2 \\ &= \frac{1}{N} \sum_{i=1}^N x_i^2 - \frac{1}{N^2} \left( \sum_{i=1}^N x_i^2 + \sum_{\substack{i,j=1 \\ i \neq j}}^N x_i x_j \right) \\ &= \frac{N-1}{N^2} \sum_{i=1}^N x_i^2 - \frac{1}{N^2} \sum_{\substack{i,j=1 \\ i \neq j}}^N x_i x_j, \end{aligned} \quad (16)$$

and the expectation value is

$$\begin{aligned} \langle m_2 \rangle &= \frac{N-1}{N} \left\langle \frac{1}{N} \sum_{i=1}^N x_i^2 \right\rangle - \frac{1}{N^2} \left\langle \sum_{\substack{i,j=1 \\ i \neq j}}^N x_i x_j \right\rangle \\ &= \frac{N-1}{N} \mu_2' - \frac{N(N-1)}{N^2} \mu^2, \end{aligned} \quad (17)$$

since there are  $N(N-1)$  terms  $x_i x_j$ , using

$$\langle x_i x_j \rangle = \langle x_i \rangle \langle x_j \rangle = \langle x_i \rangle^2, \quad (18)$$

and where  $\mu'_2$  is the MOMENT about 0. Using the identity

$$\mu'_2 = \mu_2 + \mu^2 \quad (19)$$

to convert to the MOMENT  $\mu_2$  about the MEAN and simplifying then gives

$$\langle m_2 \rangle = \frac{N-1}{N} \mu_2 \quad (20)$$

The factor  $(N-1)/N$  is known as BESSEL'S CORRECTION.

The third MOMENT is

$$\begin{aligned} m_3 &\equiv \langle (x - \mu)^3 \rangle = \langle x^3 - 3\mu x^2 + 3\mu^2 x - \mu^3 \rangle \\ &= \langle x^3 \rangle - 3\mu \langle x^2 \rangle + 3\mu^2 \langle x \rangle - \mu^3 \\ &= \langle x^3 \rangle - 3\mu \langle x^2 \rangle + 3\mu^3 - \mu^3 \\ &= \langle x^3 \rangle - 3\mu \langle x^2 \rangle + 2\mu^3 \\ &= \frac{1}{N} \sum x_i^3 - 3 \left( \frac{1}{N} \sum x_i \right) \left( \frac{1}{N} \sum x_j^2 \right) \\ &\quad + 2 \left( \frac{1}{N} \sum x_i \right)^3 \\ &= \frac{1}{N} \sum x_i^3 - \frac{3}{N^2} \left( \sum x_i \right) \left( \sum x_j^2 \right) \\ &\quad + \frac{2}{N^3} \left( \sum x_i \right)^3. \end{aligned} \quad (21)$$

Now use the identities

$$\left( \sum x_i^2 \right) \left( \sum x_j \right) = \sum x_i^3 + \sum x_i^2 x_j \quad (22)$$

$$\left( \sum x_i \right)^3 = \sum x_i^3 + 3 \sum x_i^2 x_j + 6 \sum x_i x_j x_k, \quad (23)$$

where it is understood that sums over products of variables exclude equal indices. Plugging in

$$\begin{aligned} m_3 &= \left( \frac{1}{N} - \frac{3}{N^2} + \frac{2}{N^3} \right) \sum x_i^3 \\ &\quad + \left( -\frac{3}{N^2} + 3 \cdot \frac{2}{N^3} \right) \sum x_i^2 x_j + 6 \cdot \frac{2}{N^3} \sum x_i x_j x_k. \end{aligned} \quad (24)$$

The expectation value is then given by

$$\begin{aligned} \langle m_3 \rangle &= \left( \frac{1}{N} - \frac{3}{N^2} + \frac{2}{N^3} \right) N \mu'_3 \\ &\quad + \left( -\frac{3}{N^2} + \frac{6}{N^3} \right) N(N-1) \mu'_2 \mu + \frac{12}{N^3} \frac{1}{6} N(N-1)(N-2) \mu^3 \end{aligned} \quad (25)$$

where  $\mu'_2$  is the MOMENT about 0. Plugging in the identities

$$\mu'_2 = \mu_2 + \mu^2 \quad (26)$$

$$\mu'_3 = \mu_3 + 3\mu_2 \mu + \mu^3 \quad (27)$$

and simplifying then gives

$$\langle m_3 \rangle = \frac{(N-1)(N-2)}{N^2} \mu_3 \quad (28)$$

(Kenney and Keeping 1951, p. 189).

The fourth MOMENT is

$$\begin{aligned} m_4 &= \langle (x - \mu)^4 \rangle = \langle x^4 - 4x^3 \mu + 6x^2 \mu^2 - 4x \mu^3 + \mu^4 \rangle \\ &= \langle x^4 \rangle - 4\mu \langle x^3 \rangle + 6\mu^2 \langle x^2 \rangle - 3\mu^4 \\ &= \frac{1}{N} \sum x_i^4 - \frac{4}{N^2} \left( \sum x_i \right) \left( \sum x_j^3 \right) \\ &\quad + \frac{6}{N^3} \left( \sum x_i \right)^2 \left( \sum x_j^2 \right) - \frac{3}{N^4} \left( \sum x_i \right)^4 \end{aligned} \quad (29)$$

Now use the identities

$$\left( \sum x_i \right) \left( \sum x_j^3 \right) = \sum x_i^4 + \sum x_i^3 x_j \quad (30)$$

$$\begin{aligned} \left( \sum x_i \right)^2 \left( \sum x_j^2 \right) &= \sum x_i^4 + 2 \sum x_i^3 x_j \\ &\quad + 2 \sum x_i^2 x_j^2 + 2 \sum x_i^2 x_j x_k \end{aligned} \quad (31)$$

$$\begin{aligned} \left( \sum x_i \right)^4 &= \sum x_i^4 + 4 \sum x_i^3 x_j + 6 \sum x_i^2 x_j^2 \\ &\quad + 12 \sum_{x_i} x_j x_k + 24 \sum x_i x_j x_k x_l. \end{aligned} \quad (32)$$

Plugging in,

$$\begin{aligned} m_4 &= \left( \frac{1}{N} - \frac{4}{N^2} + \frac{6}{N^3} - \frac{3}{N^4} \right) \sum x_i^4 \\ &\quad + \left( -\frac{4}{N^2} + 2 \cdot \frac{6}{N^3} - 4 \cdot \frac{3}{N^4} \right) \sum x_i^3 x_j \\ &\quad + \left( 2 \cdot \frac{6}{N^3} - 6 \cdot \frac{3}{N^4} \right) \sum x_i^2 x_j^2 \\ &\quad + \left( 2 \cdot \frac{6}{N^3} - 12 \cdot \frac{3}{N^4} \right) \sum x_i^2 x_j x_k \\ &\quad - 24 \cdot \frac{3}{N^4} \sum x_i x_j x_k x_l. \end{aligned} \quad (33)$$

The expectation value is then given by

$$\begin{aligned} \langle m_4 \rangle &= \left( \frac{1}{N} - \frac{4}{N^2} + \frac{6}{N^3} - \frac{3}{N^4} \right) N \mu'_4 \\ &\quad + \left( -\frac{4}{N^2} + \frac{12}{N^3} - \frac{12}{N^4} \right) N(N-1) \mu'_3 \mu \\ &\quad + \left( \frac{12}{N^3} - \frac{18}{N^4} \right) \frac{1}{2} N(N-1) \mu'^2_2 \\ &\quad + \left( \frac{18}{N^3} - \frac{36}{N^4} \right) \frac{1}{2} N(N-1)(N-2) \mu'_2 \mu^2 \\ &\quad - \frac{72}{N^4} \frac{1}{24} N(N-1)(N-2)(N-3) \mu^4, \end{aligned} \quad (34)$$

where  $\mu'_i$  are MOMENTS about 0. Using the identities

$$\mu'_2 = \mu_2 + \mu^2 \quad (35)$$

$$\mu'_3 = \mu_3 + 3\mu_2 \mu + \mu^3 \quad (36)$$

$$\mu'_4 = \mu_4 + 4\mu_3 \mu + 6\mu_2 \mu^2 + \mu^4 \quad (37)$$

and simplifying gives

$$\langle m_4 \rangle = \frac{(N-1)[(N^2-3N+3)\mu_4 + 3(2N-3)\mu_2^2]}{N^3} \quad (38)$$

(Kenney and Keeping 1951, p. 189).

The square of the second moment is

$$\begin{aligned} m_2^2 &= (\langle x^2 \rangle - \mu^2)^2 = \langle x^2 \rangle^2 - 2\mu^2 \langle x^2 \rangle + \mu^4 \\ &= \left( \frac{1}{N} \sum x_i^2 \right)^2 - 2 \left( \frac{1}{N} \sum x_i \right)^2 \left( \frac{1}{N} \sum x_i^2 \right) \\ &\quad + \left( \frac{1}{N} \sum x_i \right)^4 \\ &= \frac{1}{N^2} \left( \sum x_i^2 \right)^2 - \frac{2}{N^3} \left( \sum x_i \right)^2 \left( \sum x_j^2 \right) \\ &\quad + \frac{1}{N^4} \left( \sum x_i \right)^4. \end{aligned} \quad (39)$$

Now use the identities

$$\left( \sum x_i^2 \right)^2 = \sum x_i^4 + 2 \sum x_i^2 x_j^2 \quad (40)$$

$$\begin{aligned} \left( \sum x_i \right)^2 \left( \sum x_j^2 \right) &= \sum x_i^4 + 2 \sum x_i^2 x_j^2 \\ &\quad + 2 \sum x_i^3 x_j + 2 \sum x_i^2 x_j x_k \end{aligned} \quad (41)$$

$$\begin{aligned} \left( \sum x_i \right)^4 &= \sum x_i^4 + 6 \sum x_i^2 x_j^2 \\ &\quad + 4 \sum x_i^3 x_j + 12 \sum_{x_i} x_j x_k + 24 \sum x_i x_j x_k x_l. \end{aligned} \quad (42)$$

Plugging in,

$$\begin{aligned} m_2^2 &= \left( \frac{1}{N^2} - \frac{2}{N^3} + \frac{1}{N^4} \right) \sum x_i^4 \\ &\quad + \left( 2 \cdot \frac{1}{N^2} - 2 \cdot \frac{2}{N^3} + 6 \cdot \frac{1}{N^4} \right) \sum x_i^2 x_j^2 \\ &\quad + \left( -2 \cdot \frac{2}{N^3} + 4 \cdot \frac{1}{N^4} \right) \sum x_i^3 x_j \\ &\quad + \left( -2 \cdot \frac{2}{N^3} + 12 \cdot \frac{1}{N^4} \right) \sum x_i^2 x_j x_k \\ &\quad + \frac{24}{N^4} \sum x_i x_j x_k x_l \end{aligned} \quad (43)$$

The expectation value is then given by

$$\begin{aligned} \langle m_2^2 \rangle &= \left( \frac{1}{N^2} - \frac{2}{N^3} + \frac{1}{N^4} \right) N\mu_4' \\ &\quad + \left( \frac{2}{N^2} - \frac{4}{N^3} + \frac{6}{N^4} \right) \frac{1}{2} N(N-1) \mu_2'^2 \\ &\quad + \left( -\frac{4}{N^3} + \frac{4}{N^4} \right) N(N-1) \mu_3' \mu \\ &\quad + \left( -\frac{4}{N^3} + \frac{12}{N^4} \right) \frac{1}{2} N(N-1)(N-2) \mu_2' \mu^2 \\ &\quad + \frac{24}{N^4} \frac{1}{24} N(N-1)(N-2)(N-3) \mu^4 \end{aligned} \quad (44)$$

where  $\mu_i'$  are MOMENTS about 0. Using the identities

$$\mu_2' = \mu_2 + \mu^2 \quad (45)$$

$$\mu_3' = \mu_3 + 3\mu_2\mu + \mu^3 \quad (46)$$

$$\mu_4' = \mu_4 + 4\mu_3\mu + 6\mu_2\mu^2 + \mu^4 \quad (47)$$

and simplifying gives

$$\langle m_2^2 \rangle = \frac{(N-1)[(N-1)\mu_4 + (N^2-2N+3)\mu_2^2]}{N^3} \quad (48)$$

(Kenney and Keeping 1951, p. 189).

The VARIANCE of  $k_2$  is given by

$$\text{var}(k_2) = \frac{\kappa_4}{N} + \frac{2}{(N-1)\kappa_2^2}, \quad (49)$$

so an unbiased estimator of  $\text{var}(k_2)$  is given by

$$\text{vâr}(k_2) = \frac{2k_2^2 N + (N-1)k_4}{N(N+1)} \quad (50)$$

(Kenney and Keeping 1951, p. 189). The VARIANCE of  $k_3$  can be expressed in terms of CUMULANTS by

$$\text{var}(k_3) = \frac{\kappa_6}{N} + \frac{9\kappa_2\kappa_4}{N-1} + \frac{9\kappa_3^2}{N-1} + \frac{6\kappa_2^3}{N(N-1)(N-2)}. \quad (51)$$

An UNBIASED ESTIMATOR for  $\text{var}(k_3)$  is

$$\text{vâr}(k_3) = \frac{6k_2^2 N(N-1)}{(N-2)(N+1)(N+3)} \quad (52)$$

(Kenney and Keeping 1951, p. 190).

Now consider a finite population. Let a sample of  $N$  be taken from a population of  $M$ . Then UNBIASED ESTIMATORS  $M_2$  for the population MEAN  $\mu$ ,  $M_2$  for the population VARIANCE  $\mu_2$ ,  $G_1$  for the population SKEWNESS  $\gamma_1$ , and  $G_2$  for the population KURTOSIS  $\gamma_2$  are

$$M_1 = \mu \quad (53)$$

$$M_2 = \frac{M-N}{N(M-1)} \mu_2 \quad (54)$$

$$G_1 = \frac{M-2N}{M-2} \sqrt{\frac{M-1}{N(M-N)}} \gamma_1 \quad (55)$$

$$\begin{aligned} G_2 &= \frac{(M-1)(M^2-6MN+M+6N^2)\gamma_2}{N(M-2)(M-3)(M-N)} \\ &\quad - \frac{6M(MN+M-N^2-1)}{N(M-2)(M-3)(M-N)} \end{aligned} \quad (56)$$

(Church 1926, p. 357; Carver 1930; Irwin and Kendall 1944; Kenney and Keeping 1951, p. 143), where  $\gamma_1$  is the sample SKEWNESS and  $\gamma_2$  is the sample KURTOSIS.

# *k*-Subset

A *k*-subset is a SUBSET containing exactly *k* elements.

see also SUBSET

# *k*-Theory

A branch of mathematics which brings together ideas from algebraic geometry, LINEAR ALGEBRA, and NUMBER THEORY. In general, there are two main types of *k*-theory: topological and algebraic.

Topological *k*-theory is the "true" *k*-theory in the sense that it came first. Topological *k*-theory has to do with VECTOR BUNDLES over TOPOLOGICAL SPACES. Elements of a *k*-theory are STABLE EQUIVALENCE classes of VECTOR BUNDLES over a TOPOLOGICAL SPACE. You can put a RING structure on the collection of STABLY EQUIVALENT bundles by defining ADDITION through the WHITNEY SUM, and MULTIPLICATION through the TENSOR PRODUCT of VECTOR BUNDLES. This defines "the reduced real topological *k*-theory of a space."

"The reduced *k*-theory of a space" refers to the same construction, but instead of REAL VECTOR BUNDLES, COMPLEX VECTOR BUNDLES are used. Topological *k*-theory is significant because it forms a generalized COHOMOLOGY theory, and it leads to a solution to the vector fields on spheres problem, as well as to an understanding of the *J*-homeomorphism of HOMOTOPY THEORY.

Algebraic *k*-theory is somewhat more involved. Swan (1962) noticed that there is a correspondence between the CATEGORY of suitably nice TOPOLOGICAL SPACES (something like regular HAUSDORFF SPACES) and *C\**-ALGEBRAS. The idea is to associate to every SPACE the *C\**-ALGEBRA of CONTINUOUS MAPS from that SPACE to the REALS.

A VECTOR BUNDLE over a SPACE has sections, and these sections can be multiplied by CONTINUOUS FUNCTIONS to the REALS. Under Swan's correspondence, VECTOR BUNDLES correspond to modules over the *C\**-ALGEBRA of CONTINUOUS FUNCTIONS, the MODULES being the modules of sections of the VECTOR BUNDLE. This study of MODULES over *C\**-ALGEBRA is the starting point of algebraic *k*-theory.

The QUILLEN-LICHTENBAUM CONJECTURE connects algebraic *k*-theory to Étale cohomology.

# *k*-Tuple Conjecture

The first of the HARDY-LITTLEWOOD CONJECTURES. The *k*-tuple conjecture states that the asymptotic number of PRIME CONSTELLATIONS can be computed explicitly. In particular, unless there is a trivial divisibility condition that stops *p*, *p* + *a*<sub>1</sub>, ..., *p* + *a*<sub>*k*</sub> from consisting of PRIMES infinitely often, then such PRIME CONSTELLATIONS will occur with an asymptotic density which is computable in terms of *a*<sub>1</sub>, ..., *a*<sub>*k*</sub>. Let 0 < *m*<sub>1</sub> < *m*<sub>2</sub> < ... < *m*<sub>*k*</sub>, then the *k*-tuple conjecture predicts that the number of PRIMES *p* ≤ *x* such that *p* + 2*m*<sub>1</sub>, *p* + 2*m*<sub>2</sub>, ..., *p* + 2*m*<sub>*k*</sub> are all PRIME is

$$P(x; m_1, m_2, \dots, m_k) \sim C(m_1, m_2, \dots, m_k) \int_2^x \frac{dt}{\ln^{k+1} t}, \quad (1)$$

where

$$C(m_1, m_2, \dots, m_k) = 2^k \prod_q \frac{1 - \frac{w(q; m_1, m_2, \dots, m_k)}{q}}{(1 - \frac{1}{q})^{k+1}}, \quad (2)$$

the product is over ODD PRIMES *q*, and

$$w(q; m_1, m_2, \dots, m_k) \quad (3)$$

denotes the number of distinct residues of 0, *m*<sub>1</sub>, ..., *m*<sub>*k*</sub> (mod *q*) (Halberstam and Richert 1974, Odlyzko). If *k* = 1, then this becomes

$$C(m) = 2 \prod_q \frac{q(q-2)}{(q-1)^2} \prod_{q|m} \frac{q-1}{q-2}. \quad (4)$$

This conjecture is generally believed to be true, but has not been proven (Odlyzko *et al.*). The following special case of the conjecture is sometimes known as the PRIME PATTERNS CONJECTURE. Let *S* be a FINITE set of INTEGERS. Then it is conjectured that there exist infinitely many *k* for which {*k* + *s* : *s* ∈ *S*} are all PRIME IFF *S* does not include all the RESIDUES of any PRIME. The TWIN PRIME CONJECTURE is a special case of the prime patterns conjecture with *S* = {0, 2}. This conjecture also implies that there are arbitrarily long ARITHMETIC PROGRESSIONS of PRIMES.

#### Kac Formula

The expected number of REAL zeros  $E_n$  of a RANDOM POLYNOMIAL of degree  $n$  is

$$E_n = \frac{1}{\pi} \int_{-\infty}^{\infty} \sqrt{\frac{1}{(t^2 - 1)^2} - \frac{(n+1)^2 t^{2n}}{(t^{2n+2} - 1)^2}} dt \quad (1)$$

$$= \frac{4}{\pi} \int_0^1 \sqrt{\frac{1}{(1-t^2)^2} - \frac{(n+1)^2 t^{2n}}{(1-t^{2n+2})^2}} dt. \quad (2)$$

As  $n \rightarrow \infty$ ,

$$E_n = \frac{2}{\pi} \ln n + C_1 + \frac{2}{\pi n} + \mathcal{O}(n^{-2}), \quad (3)$$

where

$$C_1 = \frac{2}{\pi} \left[ \ln 2 + \int_0^{\infty} \left( \sqrt{\frac{1}{x^2} - \frac{4e^{-2x}}{(1-e^{-2x})^2}} - \frac{1}{x+1} \right) dx \right] = 0.6257358072 \dots \quad (4)$$

The initial term was derived by Kac (1943).

#### Kac Matrix

The  $(n+1) \times (n+1)$  TRIDIAGONAL MATRIX (also called the CLEMENT MATRIX) defined by

$$S_n = \begin{bmatrix} 0 & n & 0 & 0 & \cdots & 0 \\ 1 & 0 & n-1 & 0 & \cdots & 0 \\ 0 & 2 & 0 & n-2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & 0 & n-1 & 0 & 1 \\ 0 & 0 & 0 & 0 & n & 0 \end{bmatrix}.$$

The EIGENVALUES are  $2k - n$  for  $k = 0, 1, \dots, n$ .

#### Kähler Manifold

A manifold for which the EXTERIOR DERIVATIVE of the FUNDAMENTAL FORM  $\Omega$  associated with the given Hermitian metric vanishes, so  $d\Omega = 0$ .

#### Takeya Needle Problem

What is the plane figure of least AREA in which a line segment of width 1 can be freely rotated (where translation of the segment is also allowed)? Besicovitch (1928) proved that there is no MINIMUM AREA. This can be seen by rotating a line segment inside a DELTOID, star-shaped 5-oid, star-shaped 7-oid, etc. When the figure is restricted to be convex, Cunningham and Schoenberg (1965) found there is still no minimum AREA. However, the smallest simple convex domain in which one can put a segment of length 1 which will coincide with itself when rotated by  $180^\circ$  is

$$\frac{1}{24}(5 - 2\sqrt{2})\pi = 0.284258 \dots$$

(Le Lionnais 1983).

### Kantrovich Inequality

Suppose  $x_1 < x_2 < \dots < x_n$  are given POSITIVE numbers. Let  $\lambda_1, \dots, \lambda_n \geq 0$  and  $\sum \lambda_j = 1$ . Then

$$\left( \sum \lambda_j x_j \right) \left( \sum \lambda_j x_j^{-1} \right) \leq A^2 G^{-2},$$

where

$$A = \frac{1}{2}(x_1 + x_n)$$

$$G = \sqrt{x_1 x_n}$$

are the ARITHMETIC and GEOMETRIC MEAN, respectively, of the first and last numbers.

### Kaplan-Yorke Conjecture

There are several versions of the Kaplan-Yorke conjecture, with many of the higher dimensional ones remaining unsettled. The original Kaplan-Yorke conjecture (Kaplan and Yorke 1979) proposed that, for a two-dimensional mapping, the CAPACITY DIMENSION  $D$  equals the KAPLAN-YORKE DIMENSION  $D_{KY}$ ,

$$D = D_{KY} = d_{Ly} = 1 + \frac{\sigma_1}{\sigma_2},$$

where  $\sigma_1$  and  $\sigma_2$  are the LYAPUNOV CHARACTERISTIC EXPONENTS. This was subsequently proven to be true in 1982. A later conjecture held that the KAPLAN-YORKE DIMENSION is generically equal to a probabilistic dimension which appears to be identical to the INFORMATION DIMENSION (Frederickson *et al.* 1983). This conjecture is partially verified by Ledrappier (1981). For invertible 2-D maps,  $\nu = \sigma = D$ , where  $\nu$  is the CORRELATION EXPONENT,  $\sigma$  is the INFORMATION DIMENSION, and  $D$  is the CAPACITY DIMENSION (Young 1984).

### Kaplan-Yorke Dimension

$$D_{KY} \equiv j + \frac{\sigma_1 + \dots + \sigma_j}{|\sigma_{j+1}|},$$

where  $\sigma_1 \leq \sigma_n$  are LYAPUNOV CHARACTERISTIC EXPONENTS and  $j$  is the largest INTEGER for which

$$\lambda_1 + \dots + \lambda_j \geq 0.$$

If  $\nu = \sigma = D$ , where  $\nu$  is the CORRELATION EXPONENT,  $\sigma$  the INFORMATION DIMENSION, and  $D$  the HAUSDORFF DIMENSION, then

$$D \leq D_{KY}$$

(Grassberger and Procaccia 1983).

### Kappa Curve

A curve also known as GUTSCHOVEN'S CURVE which was first studied by G. van Gutschoven around 1662 (MacTutor Archive). It was also studied by Newton and, some years later, by Johann Bernoulli. It is given by the Cartesian equation

$$(x^2 + y^2)y^2 = a^2 x^2, \quad (1)$$

by the polar equation

$$r = a \cot \theta, \quad (2)$$

and the parametric equations

$$x = a \cos t \cot t \quad (3)$$

$$y = a \cos t. \quad (4)$$

### Kaprekar Number

Consider an  $n$ -digit number  $k$ . Square it and add the right  $n$  digits to the left  $n$  or  $n-1$  digits. If the resultant sum is  $k$ , then  $k$  is called a Kaprekar number. The first few are 1, 9, 45, 55, 99, 297, 703, ... (Sloane's A006886).

$$9^2 = 81 \quad 8 + 1 = 9$$

$$297^2 = 88,209 \quad 88 + 209 = 297.$$

### Kaprekar Routine

A routine discovered in 1949 by D. R. Kaprekar for 4-digit numbers, but which can be generalized to  $k$ -digit numbers. To apply the Kaprekar routine to a number  $n$ , arrange the digits in descending ( $n'$ ) and ascending ( $n''$ ) order. Now compute  $K(n) \equiv n' - n''$  and iterate. The algorithm reaches 0 (a degenerate case), a constant,

or a cycle, depending on the number of digits in  $k$  and the value of  $n$ .

For a 3-digit number  $n$  in base 10, the Kaprekar routine reaches the number 495 in at most six iterations. In base  $r$ , there is a unique number  $((r-2)/2, r-1, r/2)_r$  to which  $n$  converges in at most  $(r+2)/2$  iterations IFF  $r$  is EVEN. For any 4-digit number  $n$  in base-10, the routine terminates on the number 6174 after seven or fewer steps (where it enters the 1-cycle  $K(6174) = 6174$ ).

#### Kapteyn Series

A series of the form

$$\sum_{n=0}^{\infty} \alpha_n J_{\nu+n}[(\nu+n)z],$$

where  $J_n(z)$  is a BESSEL FUNCTION OF THE FIRST KIND. Examples include Kapteyn's original series

$$\frac{1}{1-z} = 1 + 2 \sum_{n=1}^{\infty} J_n(nz)$$

and

$$\frac{z^2}{2(1-z^2)} = \sum_{n=1}^{\infty} J_{2n}(2nz).$$

#### Karatsuba Multiplication

It is possible to perform MULTIPLICATION of LARGE NUMBERS in (many) fewer operations than the usual brute-force technique of "long multiplication." As discovered by Karatsuba and Ofman (1962), MULTIPLICATION of two  $n$ -DIGIT numbers can be done with a BIT COMPLEXITY of less than  $n^2$  using identities of the form

$$(a + b \cdot 10^n)(c + d \cdot 10^n) = ac + [(a+b)(c+d) - ac - bd]10^n + bd \cdot 10^{2n}. \quad (1)$$

Proceeding recursively then gives BIT COMPLEXITY  $\mathcal{O}(n^{\lg 3})$ , where  $\lg 3 = 1.58... < 2$  (Borwein *et al.* 1989). The best known bound is  $\mathcal{O}(n \lg n \lg \lg n)$  steps for  $n \gg 1$  (Schönhage and Strassen 1971, Knuth 1981). However, this ALGORITHM is difficult to implement, but a procedure based on the FAST FOURIER TRANSFORM is straightforward to implement and gives BIT COMPLEXITY  $\mathcal{O}((\lg n)^{2+\epsilon}n)$  (Brigham 1974, Borodin and Munro 1975, Knuth 1981, Borwein *et al.* 1989).

As a concrete example, consider MULTIPLICATION of two numbers each just two "digits" long in base  $w$ ,

$$N_1 = a_0 + a_1 w \quad (2)$$

$$N_2 = b_0 + b_1 w, \quad (3)$$

then their PRODUCT is

$$\begin{aligned} P &\equiv N_1 N_2 \\ &= a_0 b_0 + (a_0 b_1 + a_1 b_0)w + a_1 b_1 w^2 \\ &= p_0 + p_1 w + p_2 w^2. \end{aligned} \quad (4)$$

Instead of evaluating products of individual digits, now write

$$q_0 = a_0 b_0 \quad (5)$$

$$q_1 = (a_0 + a_1)(b_0 + b_1) \quad (6)$$

$$q_2 = a_1 b_1. \quad (7)$$

The key term is  $q_1$ , which can be expanded, regrouped, and written in terms of the  $p_j$  as

$$q_1 = p_1 + p_0 + p_2. \quad (8)$$

However, since  $p_0 = q_0$ , and  $p_2 = q_2$ , it immediately follows that

$$p_0 = q_0 \quad (9)$$

$$p_1 = q_1 - q_0 - q_2 \quad (10)$$

$$p_2 = q_2, \quad (11)$$

so the three "digits" of  $p$  have been evaluated using three multiplications rather than four. The technique can be generalized to multidigit numbers, with the trade-off being that more additions and subtractions are required.

Now consider four-"digit" numbers

$$N_1 = a_0 + a_1 w + a_2 w^2 + a_3 w^3, \quad (12)$$

which can be written as a two-"digit" number represented in the base  $w^2$ ,

$$N_1 = (a_0 + a_1 w) + (a_2 + a_3 w) * w^2. \quad (13)$$

The "digits" in the new base are now

$$a'_0 = a_0 + a_1 w \quad (14)$$

$$a'_1 = a_2 + a_3 w, \quad (15)$$

and the Karatsuba algorithm can be applied to  $N_1$  and  $N_2$  in this form. Therefore, the Karatsuba algorithm is not restricted to multiplying two-digit numbers, but more generally expresses the multiplication of two numbers in terms of multiplications of numbers of half the size. The asymptotic speed the algorithm obtains by recursive application to the smaller required subproducts is  $\mathcal{O}(n^{\lg 3})$  (Knuth 1981).

When this technique is recursively applied to multidigit numbers, a point is reached in the recursion when the overhead of additions and subtractions makes it more efficient to use the usual  $\mathcal{O}(n^2)$  MULTIPLICATION algorithm to evaluate the partial products. The most efficient overall method therefore relies on a combination of Karatsuba and conventional multiplication.

## Katona's Problem

Find the minimum number  $f(n)$  of subsets in a SEPARATING FAMILY for a SET of  $n$  elements, where a SEPARATING FAMILY is a SET of SUBSETS in which each pair of adjacent elements is found separated, each in one of two disjoint subsets. For example, the 26 letters of the alphabet can be separated by a family of nine:

$$\begin{array}{lll} (abcdefghi) & (jklmnopqr) & (stuvwxyz) \\ (abcjklstu) & (defmnovwx) & (ghipqryz) \\ (adgjmpsvy) & (behknqtzw) & (cfilorux) \end{array}$$

The problem was posed by Katona (1973) and solved by C. Mao-Cheng in 1982,

$$f(n) = \min \left\{ 2p + 3 \left\lceil \log_3 \left( \frac{n}{2^p} \right) \right\rceil : p = 0, 1, 2 \right\},$$

where  $\lceil x \rceil$  is the CEILING FUNCTION.  $f(n)$  is nondecreasing, and the values for  $n = 1, 2, \dots$  are 0, 2, 3, 4, 5, 5, 6, 6, 6, 7,  $\dots$  (Sloane's A07600). The values at which  $f(n)$  increases are 1, 2, 3, 4, 5, 7, 10, 13, 19, 28, 37,  $\dots$  (Sloane's A007601), so  $f(26) = 9$ , as illustrated in the preceding example.

### Kauffman Polynomial $F$

A semi-oriented 2-variable KNOT POLYNOMIAL defined by

$$F_L(a, z) = a^{-w(L)} \langle |L| \rangle, \quad (1)$$

where  $L$  is an oriented LINK DIAGRAM,  $w(L)$  is the WRITHE of  $L$ ,  $|L|$  is the unoriented diagram corresponding to  $L$ , and  $\langle L \rangle$  is the BRACKET POLYNOMIAL. It was developed by Kauffman by extending the BLM/HO POLYNOMIAL  $Q$  to two variables, and satisfies

$$F(1, x) = Q(x). \quad (2)$$

The Kauffman POLYNOMIAL is a generalization of the JONES POLYNOMIAL  $V(t)$  since it satisfies

$$V(t) = F(-t^{-3/4}, t^{-1/4} + t^{1/4}), \quad (3)$$

but its relationship to the HOMFLY POLYNOMIAL is not well understood. In general, it has more terms than the HOMFLY POLYNOMIAL, and is therefore more powerful for discriminating KNOTS. It is a semi-oriented POLYNOMIAL because changing the orientation only changes  $F$  by a POWER of  $a$ . In particular, suppose  $L^*$  is obtained from  $L$  by reversing the orientation of component  $k$ , then

$$F_{L^*} = a^{4\lambda} F_L, \quad (4)$$

where  $\lambda$  is the LINKING NUMBER of  $k$  with  $L - k$  (Lickorish and Millett 1988).  $F$  is unchanged by MUTATION.

$$F_{L_1 + F_{L_2}} = F(L_1)F(L_2) \quad (5)$$

$$F_{L_1 \cup L_2} = [(a^{-1} + a)x^{-1} - 1]F_{L_1}F_{L_2}. \quad (6)$$

M. B. Thistlethwaite has tabulated the Kauffman 2-variable POLYNOMIAL for KNOTS up to 13 crossings.

### Kauffman Polynomial $X$

A 1-variable KNOT POLYNOMIAL denoted  $X$  or  $\mathcal{L}$ .

$$\mathcal{L}_L(A) \equiv (-A^3)^{-w(L)} \langle L \rangle, \quad (1)$$

where  $\langle L \rangle$  is the BRACKET POLYNOMIAL and  $w(L)$  is the WRITHE of  $L$ . This POLYNOMIAL is invariant under AMBIENT ISOTOPY, and relates MIRROR IMAGES by

$$\mathcal{L}_{L^*} = \mathcal{L}_L(A^{-1}). \quad (2)$$

It is identical to the JONES POLYNOMIAL with the change of variable

$$\mathcal{L}(t^{-1/4}) = V(t). \quad (3)$$

The  $X$  POLYNOMIAL of the MIRROR IMAGE  $K^*$  is the same as for  $K$  but with  $A$  replaced by  $A^{-1}$ .

### Keith Number

A Keith number is an  $n$ -digit INTEGER  $N$  such that if a Fibonacci-like sequence (in which each term in the sequence is the sum of the  $n$  previous terms) is formed with the first  $n$  terms taken as the decimal digits of the number  $N$ , then  $N$  itself occurs as a term in the sequence. For example, 197 is a Keith number since it generates the sequence 1, 9, 7, 17, 33, 57, 107, 197, ... (Keith). Keith numbers are also called REPFIGIT NUMBERS.

There is no known general technique for finding Keith numbers except by exhaustive search. Keith numbers are much rarer than the PRIMES, with only 52 Keith numbers with  $< 15$  digits: 14, 19, 28, 47, 61, 75, 197, 742, 1104, 1537, 2208, 2580, 3684, 4788, 7385, 7647, 7909, ... (Sloane's A007629). In addition, three 15-digit Keith numbers are known (Keith 1994). It is not known if there are an INFINITE number of Keith numbers.

### Keller's Conjecture

Keller conjectured that tiling an  $n$ -D space with  $n$ -D HYPERCUBES of equal size yields an arrangement in which at least two hypercubes have an entire  $(n - 1)$ -D "side" in common. The CONJECTURE has been proven true for  $n = 1$  to 6, but disproven for  $n \geq 10$ .

### Kelvin Functions

Kelvin defined the Kelvin functions BEI and BER according to

$$J_\nu(xe^{3\pi i/4}) = \text{ber}_\nu(x) + i \text{bei}_\nu(x), \quad (1)$$

where  $J_\nu(s)$  is a BESSEL FUNCTION OF THE FIRST KIND, and the functions KEI and KER by

$$e^{-\nu\pi i/2} K_\nu(xe^{\pi i/4}) = \text{ker}_\nu(x) + i \text{kei}_\nu(x), \quad (2)$$

where  $K_\nu(x)$  is a MODIFIED BESSEL FUNCTION OF THE SECOND KIND. For the special case  $\nu = 0$ ,

$$J_0(i\sqrt{i}x) = J_0(\tfrac{1}{2}\sqrt{2}(i-1)x) \equiv \text{ber}(x) + i \text{bei}(x). \quad (3)$$

see also BEI, BER, KEI, KER

- Spanier, J. and Oldham, K. B. "The Kelvin Functions." Ch. 55 in *An Atlas of Functions*. Washington, DC: Hemisphere, pp. 543–554, 1987.

### Kelvin Transformation

The transformation

$$v(x'_1, \dots, x'_n) = \left(\frac{a}{r'}\right)^{n-2} u\left(\frac{a^2 x'_1}{r'^2}, \dots, \frac{a^2 x'_n}{r'^2}\right),$$

where

$$r'^2 = x_1'^2 + \dots + x_n'^2.$$

If  $u(x_1, \dots, x_n)$  is a HARMONIC FUNCTION on a DOMAIN  $D$  of  $\mathbb{R}^n$  (with  $n \geq 3$ ), then  $v(x'_1, \dots, x'_n)$  is HARMONIC on  $D'$ .

### Kepler Conjecture

In 1611, Kepler proposed that close packing (cubic or hexagonal) is the densest possible SPHERE PACKING (has the greatest  $\eta$ ), and this assertion is known as the Kepler conjecture. Finding the densest (not necessarily periodic) packing of spheres is known as the KEPLER PROBLEM.

A putative proof of the Kepler conjecture was put forward by W.-Y. Hsiang (Hsiang 1992, Cipra 1993), but was subsequently determined to be flawed (Conway *et al.* 1994, Hales 1994). According to J. H. Conway, nobody who has read Hsiang's proof has any doubts about its validity: it is nonsense.

### Kepler's Equation

Let  $M$  be the mean anomaly and  $E$  the ECCENTRIC ANOMALY of a body orbiting on an ELLIPSE with ECCENTRICITY  $e$ , then

$$M = E - e \sin E. \quad (1)$$

For  $M$  not a multiple of  $\pi$ , Kepler's equation has a unique solution, but is a TRANSCENDENTAL EQUATION and so cannot be inverted and solved directly for  $E$  given an arbitrary  $M$ . However, many algorithms have been derived for solving the equation as a result of its importance in celestial mechanics.

Writing a  $E$  as a POWER SERIES in  $e$  gives

$$E = M + \sum_{n=1}^{\infty} a_n e^n, \quad (2)$$

where the coefficients are given by the LAGRANGE INVERSION THEOREM as

$$a_n = \frac{1}{2^{n-1}n!} \sum_{k=0}^{\lfloor n/2 \rfloor} (-1)^k \binom{n}{k} (n-2k)^{n-1} \sin[(n-2k)M] \quad (3)$$

(Wintner 1941, Moulton 1970, Henrici 1974, Finch). Surprisingly, this series diverges for

$$e > 0.6627434193\dots, \quad (4)$$

a value known as the LAPLACE LIMIT. In fact,  $E$  converges as a GEOMETRIC SERIES with ratio

$$r = \frac{e}{1 + \sqrt{1+e^2}} \exp(\sqrt{1+e^2}) \quad (5)$$

(Finch).

There is also a series solution in BESSEL FUNCTIONS OF THE FIRST KIND,

$$E = M + \sum_{n=1}^{\infty} \frac{2}{n} J_n(ne) \sin(nM). \quad (6)$$

This series converges for all  $e < 1$  like a GEOMETRIC SERIES with ratio

$$r = \frac{e}{1 + \sqrt{1-e^2}} \exp(\sqrt{1-e^2}). \quad (7)$$

The equation can also be solved by letting  $\psi$  be the ANGLE between the planet's motion and the direction PERPENDICULAR to the RADIUS VECTOR. Then

$$\tan \psi = \frac{e \sin E}{\sqrt{1-e^2}}. \quad (8)$$

Alternatively, we can define  $e$  in terms of an intermediate variable  $\phi$

$$e \equiv \sin \phi, \quad (9)$$

then

$$\sin[\tfrac{1}{2}(v-E)] = \sqrt{\frac{r}{p}} \sin(\tfrac{1}{2}\phi) \sin v \quad (10)$$

$$\sin[\tfrac{1}{2}(v+E)] = \sqrt{\frac{r}{p}} \cos(\tfrac{1}{2}\phi) \sin v. \quad (11)$$

Iterative methods such as the simple

$$E_{i+1} = M + e \sin E_i \quad (12)$$

with  $E_0 = 0$  work well, as does NEWTON'S METHOD,

$$E_{i+1} = E_i + \frac{M + e \sin E_i - E_i}{1 - e \cos E_i}. \quad (13)$$

In solving Kepler's equation, Stieltjes required the solution to

$$e^x(x-1) = e^{-x}(x+1), \quad (14)$$

which is 1.1996678640257734... (Goursat 1959, Le Lionnais 1983).

Gray, A. *Modern Differential Geometry of Curves and Surfaces*. Boca Raton, FL: CRC Press, pp. 71–72, 1993.

**Kepler-Poinsot Solid**

The Kepler-Poinsot solids are the four regular CONCAVE POLYHEDRA with intersecting facial planes. They are composed of regular CONCAVE POLYGONS and were unknown to the ancients. Kepler discovered two of them about 1619. These two were subsequently rediscovered by Poinsot, who also discovered the other two, in 1809. As shown by Cauchy, they are stellated forms of the DODECAHEDRON and ICOSAHEDRON.

The Kepler-Poinsot solids, illustrated above, are known as the GREAT DODECAHEDRON, GREAT ICOSAHEDRON, GREAT STELLATED DODECAHEDRON, and SMALL STELLATED DODECAHEDRON. Cauchy (1813) proved that these four exhaust all possibilities for regular star polyhedra (Ball and Coxeter 1987).

A table listing these solids, their DUALS, and COMPOUNDS is given below.

Polyhedron	Dual
great dodecahedron	small stellated dodec.
great icosahedron	great stellated dodec.
great stellated dodec.	great icosahedron
small stellated dodec.	great dodecahedron

Polyhedron	Compound
great dodecahedron	great dodecahedron-small stellated dodec.
great icosahedron	great icosahedron-great stellated dodec.
great stellated dodec.	great icosahedron-great stellated dodec.
small stellated dodec.	great dodecahedron-small stellated dodec.

The polyhedra  $\{\frac{5}{2}, 5\}$  and  $\{5, \frac{5}{2}\}$  fail to satisfy the POLYHEDRAL FORMULA

$$V - E + F = 2,$$

where  $V$  is the number of faces,  $E$  the number of edges, and  $F$  the number of faces, despite the fact that formula holds for all ordinary polyhedra (Ball and Coxeter 1987). This unexpected result led none less than Schläfli (1860) to conclude that they could not exist.

In 4-D, there are 10 Kepler-Poinsot solids, and in  $n$ -D with  $n \geq 5$ , there are none. In 4-D, nine of the solids have the same VERTICES as  $\{3, 3, 5\}$ , and the tenth has the same as  $\{5, 3, 3\}$ . Their SCHLÄFLI SYMBOLS are  $\{\frac{5}{2}, 5, 3\}$ ,  $\{3, 5, \frac{5}{2}\}$ ,  $\{5, \frac{5}{2}, 5\}$ ,  $\{\frac{5}{2}, 3, 5\}$ ,  $\{5, 3, \frac{5}{2}\}$ ,  $\{\frac{5}{2}, 5, \frac{5}{2}\}$ ,  $\{5, \frac{5}{2}, 3\}$ ,  $\{3, \frac{5}{2}, 5\}$ ,  $\{\frac{5}{2}, 3, 3\}$ , and  $\{3, 3, \frac{5}{2}\}$ .

Coxeter *et al.* (1954) have investigated star "Archimedean" polyhedra.

**Khinchin Constant**

see KHINTCHINE'S CONSTANT

**Khinchine's Constant**

N.B. A detailed on-line essay by S. Finch was the starting point for this entry.

$$x = [q_0, q_1, \dots] = q_0 + \frac{1}{q_1 + \frac{1}{q_2 + \frac{1}{q_3 + \dots}}} \quad (1)$$

be the SIMPLE CONTINUED FRACTION of a REAL NUMBER  $x$ , where the numbers  $q_i$  are called PARTIAL QUOTIENTS. Khinchine (1934) considered the limit of the GEOMETRIC MEAN

$$G_n(x) = (q_1 q_2 \dots q_n)^{1/n} \quad (2)$$

as  $n \rightarrow \infty$ . Amazingly enough, this limit is a constant independent of  $x$ —except if  $x$  belongs to a set of MEASURE 0—given by

$$K = 2.685452001\dots \quad (3)$$

(Sloane's A002210), as proved in Kac (1959). The values  $G_n(x)$  are plotted above for  $n = 1$  to 500 and  $x = \pi$ ,  $1/\pi$ ,  $\sin 1$ , the EULER-MASCHERONI CONSTANT  $\gamma$ , and the COPELAND-ERDŐS CONSTANT. REAL NUMBERS  $x$  for which  $\lim_{n \rightarrow \infty} G_n(x) \neq K$  include  $x = e$ ,  $\sqrt{2}$ ,  $\sqrt{3}$ , and the GOLDEN RATIO  $\phi$ , all of which have periodic PARTIAL QUOTIENTS, plotted below.

The CONTINUED FRACTION for  $K$  is  $[2, 1, 2, 5, 1, 1, 2, 1, 1, \dots]$  (Sloane's A002211). It is not known if  $K$  is IRRATIONAL, let alone TRANSCENDENTAL. Bailey *et al.* (1995) have computed  $K$  to 7350 DIGITS.

Explicit expressions for  $K$  include

$$K = \prod_{n=1}^{\infty} \left[ 1 + \frac{1}{n(n+2)} \right]^{\ln n / \ln 2} \quad (4)$$

$$\ln 2 \ln K = \frac{1}{12} \pi^2 + \frac{1}{2} (\ln 2)^2 + \int_0^{\pi} \frac{\ln(\theta |\cot \theta|) d\theta}{\theta} \quad (5)$$

$$\ln K = \frac{1}{\ln 2} \sum_{m=1}^{\infty} \frac{h_{m-1}}{m} [\zeta(2m) - 1], \quad (6)$$

where  $\zeta(z)$  is the RIEMANN ZETA FUNCTION and

$$h_m = \sum_{j=1}^m \frac{(-1)^{j-1}}{j} \quad (7)$$

(Shanks and Wrench 1959). Gosper gave

$$\ln K = \frac{1}{\ln 2} \sum_{j=2}^{\infty} \frac{(-1)^j (2-2^j) \zeta'(j)}{j}, \quad (8)$$

where  $\zeta'(z)$  is the DERIVATIVE of the RIEMANN ZETA FUNCTION. An extremely rapidly converging sum also due to Gosper is

$$\begin{aligned} \ln K = \frac{1}{\ln 2} \sum_{k=0}^{\infty} \left\{ -\ln(k+1) [\ln(k+3) \right. \\ \left. - 2\ln(k+2) + \ln(k+1)] \right. \\ \left. - \frac{(-1)^k (2-2^{k+2})}{k+2} \left[ \frac{\ln(k+1)}{(k+1)^{k+2}} - \zeta'(k+2, k+2) \right] \right. \\ \left. + \ln(k+1) \left[ \sum_{s=1}^{k+2} \frac{(-1)^s (2-2^s)}{(k+1)^s s} \right] \right\}, \quad (9) \end{aligned}$$

where  $\zeta(s, a)$  is the HURWITZ ZETA FUNCTION.

Khintchine's constant is also given by the integral

$$\ln 2 \ln \left( \frac{1}{2} K \right) = \int_0^1 \frac{1}{x(1+x)} \ln \left[ \frac{\pi x(1-x^2)}{\sin(\pi x)} \right] dx. \quad (10)$$

If  $P_n/Q_n$  is the  $n$ th CONVERGENT of the CONTINUED FRACTION of  $x$ , then

$$\lim_{n \rightarrow \infty} (Q_n)^{1/n} = \lim_{n \rightarrow \infty} \left( \frac{P_n}{x} \right)^{1/n} = e^{\pi^2 / (12 \ln 2)} \approx 3.27582 \quad (11)$$

for almost all REAL  $x$  (Lévy 1936, Finch). This number is sometimes called the LÉVY CONSTANT, and the argument of the exponential is sometimes called the KHintchine-LÉVY CONSTANT.

Define the following quantity in terms of the  $k$ th partial quotient  $q_k$ ,

$$M(s, n, x) = \left( \frac{1}{n} \sum_{k=1}^n q_k^s \right)^{1/s}. \quad (12)$$

Then

$$\lim_{n \rightarrow \infty} M(1, n, x) = \infty \quad (13)$$

for almost all real  $x$  (Khintchine, Knuth 1981, Finch), and

$$M(1, n, x) \sim \mathcal{O}(\ln n). \quad (14)$$

Furthermore, for  $s < 1$ , the limiting value

$$\lim_{n \rightarrow \infty} M(s, n, x) = K(s) \quad (15)$$

exists and is a constant  $K(s)$  with probability 1 (Rockett and Szűsz 1992, Khintchine 1997).

see KIEPERT'S HYPERBOLA, KIEPERT'S PARABOLA

## Kiepert's Hyperbola

A curve which is related to the solution of LEMOINE'S PROBLEM and its generalization to ISOSCELES TRIANGLES constructed on the sides of a given TRIANGLE. The VERTICES of the constructed TRIANGLES are

$$A' = -\sin \phi : \sin(C + \phi) : \sin(B + \phi) \quad (1)$$

$$B' = \sin(C + \phi) : -\sin \phi : \sin(A + \phi) \quad (2)$$

$$C' = \sin(B + \phi) : \sin(A + \phi) : -\sin \phi, \quad (3)$$

where  $\phi$  is the base ANGLE of the ISOSCELES TRIANGLE. Kiepert showed that the lines connecting the VERTICES of the given TRIANGLE and the corresponding peaks of the ISOSCELES TRIANGLES CONCUR. The TRILINEAR COORDINATES of the point of concurrence are

$$\sin(B + \phi) \sin(C + \phi) : \sin(C + \phi) \sin(A + \phi) : \sin(A + \phi) \sin(B + \phi). \quad (4)$$

The locus of this point as the base ANGLE varies is given by the curve

$$\frac{\sin(B - C)}{\alpha} + \frac{\sin(C - A)}{\beta} + \frac{\sin(A - B)}{\gamma} = \frac{bc(c^2 - c^2)}{\alpha} + \frac{ca(c^2 - a^2)}{\beta} + \frac{ab(a^2 - b^2)}{\gamma} = 0. \quad (5)$$

Writing the TRILINEAR COORDINATES as

$$\alpha_i = d_i s_i, \quad (6)$$

where  $d_i$  is the distance to the side opposite  $\alpha_i$  of length  $s_i$  and using the POINT-LINE DISTANCE FORMULA with  $(x_0, y_0)$  written as  $(x, y)$ ,

$$d_i = \frac{|(y_{i+2} - y_{i+1})(x - x_{i+1}) - (x_{i+2} - x_{i+1})(y - y_{i+1})|}{s_i}, \quad (7)$$

where  $y_4 \equiv y_1$  and  $y_5 \equiv y_2$  gives the FORMULA

$$\sum_{i=1}^3 s_{i+1} s_{i+2} (s_{i+1}^2 - s_{i+2}^2) \times \frac{s_i}{(y_{i+2} - y_{i+1})(x - x_{i+1}) - (x_{i+2} - x_{i+1})(y - y_{i+1})} = 0 \quad (8)$$

$$\sum_{i=1}^3 \frac{(s_{i+1}^2 - s_{i+2}^2)}{(y_{i+2} - y_{i+1})(x - x_{i+1}) - (x_{i+2} - x_{i+1})(y - y_{i+1})} = 0. \quad (9)$$

Bringing this equation over a common DENOMINATOR then gives a quadratic in  $x$  and  $y$ , which is a CONIC SECTION (in fact, a HYPERBOLA). The curve can also be written as  $\csc(A + t) : \csc(B + t) : \csc(C + t)$ , as  $t$  varies over  $[-\pi/4, \pi/4]$ .

Kiepert's hyperbola passes through the triangle's CENTROID  $M$  ( $\phi = 0$ ), ORTHOCENTER  $H$  ( $\phi = \pi/2$ ), VERTICES  $A$  ( $\phi = -\alpha$  if  $\alpha \leq \pi/2$  and  $\phi = \pi - \alpha$  if  $\alpha > \pi/2$ ),  $B$  ( $\phi = -\beta$ ),  $C$  ( $\phi = -\gamma$ ), FERMAT POINT  $F_1$  ( $\phi = \pi/3$ ), second ISOGONIC CENTER  $F_2$  ( $\phi = -\pi/3$ ), ISOGONAL CONJUGATE of the BROCARD MIDPOINT ( $\phi = \omega$ ), and BROCARD'S THIRD POINT  $Z_3$  ( $\phi = \omega$ ), where  $\omega$  is the BROCARD ANGLE (Eddy and Fritsch 1994, p. 193).

The ASYMPTOTES of Kiepert's hyperbola are the SIMSON LINES of the intersections of the BROCARD AXIS with the CIRCUMCIRCLE. Kiepert's hyperbola is a RECTANGULAR HYPERBOLA. In fact, all nondegenerate conics through the VERTICES and ORTHOCENTER of a TRIANGLE are RECTANGULAR HYPERBOLAS the centers

of which lie halfway between the ISOGONIC CENTERS and on the NINE-POINT CIRCLE. The LOCUS of centers of these HYPERBOLAS is the NINE-POINT CIRCLE.

The ISOGONAL CONJUGATE curve of Kiepert's hyperbola is the BROCARD AXIS. The center of the INCIRCLE of the TRIANGLE constructed from the MIDPOINTS of the sides of a given TRIANGLE lies on Kiepert's hyperbola of the original TRIANGLE.

#### Kiepert's Parabola

Let three similar ISOSCELES TRIANGLES  $\Delta A'BC$ ,  $\Delta AB'C$ , and  $\Delta ABC'$  be constructed on the sides of a TRIANGLE  $\Delta ABC$ . Then the ENVELOPE of the axis of the TRIANGLES  $\Delta ABC$  and  $\Delta A'B'C'$  is Kiepert's parabola, given by

$$\frac{\sin A(\sin^2 B - \sin^2 C)}{u} + \frac{\sin B(\sin^2 C - \sin^2 A)}{v} + \frac{\sin C(\sin^2 A - \sin^2 B)}{w} = 0 \quad (1)$$

$$\frac{a(b^2 - c^2)}{u} + \frac{b(c^2 - a^2)}{v} + \frac{c(a^2 - b^2)}{w} = 0, \quad (2)$$

where  $[u, v, w]$  are the TRILINEAR COORDINATES for a line tangent to the parabola. It is tangent to the sides of the TRIANGLE, the line at infinity, and the LEMOINE LINE. The FOCUS has TRIANGLE CENTER FUNCTION

$$\alpha = \csc(B - C). \quad (3)$$

The EULER LINE of a triangle is the DIRECTRIX of Kiepert's parabola. In fact, the DIRECTRICES of all parabolas inscribed in a TRIANGLE pass through the ORTHOCENTER. The BRIANCHON POINT for Kiepert's parabola is the STEINER POINT.

see also BRIANCHON POINT, ENVELOPE, EULER LINE, ISOSCELES TRIANGLE, LEMOINE LINE, STEINER POINTS

#### Kieroid

Let the center  $B$  of a CIRCLE of RADIUS  $a$  move along a line  $BA$ . Let  $O$  be a fixed point located a distance  $c$  away from  $AB$ . Draw a SECANT LINE through  $O$  and  $D$ , the MIDPOINT of the chord cut from the line  $DE$  (which is parallel to  $AB$ ) and a distance  $b$  away. Then the LOCUS of the points of intersection of  $OD$  and the CIRCLE  $P_1$  and  $P_2$  is called a kieroid.

Special Case	Curve
$b = 0$	conchoid of Nicomedes
$b = a$	cissoid plus asymptote
$b = a = -c$	strophoid plus asymptote

#### References

#### Killing's Equation

The equation defining KILLING VECTORS.

$$\mathcal{L}_X g_{ab} = X_{a;b} + X_{b;a} = 2X_{(a;b)} = 0,$$

where  $\mathcal{L}$  is the LIE DERIVATIVE.

see also KILLING VECTORS

#### Killing Vectors

If any set of points is displaced by  $X^i dx_i$  where all distance relationships are unchanged (i.e., there is an ISOMETRY), then the VECTOR field is called a Killing vector.

$$g_{ab} = \frac{\partial x'^c}{\partial x^a} \frac{\partial x'^d}{\partial x^b} g_{cd}(x'), \quad (1)$$

so let

$$\begin{aligned} x'^a &= x^a + \epsilon x^a \\ \frac{\partial x'^a}{\partial x^b} &= \delta_b^a + \epsilon x^a_{,b} \end{aligned} \quad (2)$$

$$\begin{aligned} g_{ab}(x) &= (\delta_a^c + \epsilon x^c_{,a}) (\delta_b^d + \epsilon x^d_{,b}) g_{cd}(x^e + \epsilon X^e) \\ &= (\delta_a^c + \epsilon x^c_{,a}) (\delta_b^d + \epsilon x^d_{,b}) [g_{cd}(x) + \epsilon X^e g_{cd}(x)_{,e} + \dots] \\ &= g_{ab}(x) + \epsilon [g_{ad} X^d_{,b} + g_{bd} X^d_{,a} + X^e g_{ab,e}] + \mathcal{O}(\epsilon^2) \\ &= \mathcal{L}_X g_{ab}, \end{aligned} \quad (3)$$

where  $\mathcal{L}$  is the LIE DERIVATIVE. An ordinary derivative can be replaced with a covariant derivative in a LIE DERIVATIVE, so we can take as the definition

$$g_{ab;c} = 0 \quad (4)$$

$$g_{ab} g^{bc} = \delta_a^c, \quad (5)$$

which gives KILLING'S EQUATION

$$\mathcal{L}_X g_{ab} = X_{a;b} + X_{b;a} = 2X_{(a;b)} = 0. \quad (6)$$

A Killing vector  $X^b$  satisfies

$$g^{bc} X_{c;ab} - R_{ab} X^b = 0 \quad (7)$$

$$X_{a;b} = R_{abcd} X^d \quad (8)$$

$$X^{a;b} + R_c^a X^c = 0, \quad (9)$$

where  $R_{ab}$  is the RICCI TENSOR and  $R_{abcd}$  is the RIE-MANN TENSOR.

A 2-sphere with METRIC

$$ds^2 = d\theta^2 + \sin^2 \theta d\phi^2 \quad (10)$$

has three Killing vectors, given by the angular momentum operators

$$\tilde{L}_x = -\cos \phi \frac{\partial}{\partial \theta} + \cot \theta \sin \phi \frac{\partial}{\partial \phi} \quad (11)$$

$$\tilde{L}_y = \sin \phi \frac{\partial}{\partial \theta} + \cot \theta \cos \phi \frac{\partial}{\partial \phi} \quad (12)$$

$$\tilde{L}_z = \frac{\partial}{\partial \phi}. \quad (13)$$

The Killing vectors in Euclidean 3-space are

$$x^1 = \frac{\partial}{\partial x} \quad (14)$$

$$x^2 = \frac{\partial}{\partial y} \quad (15)$$

$$x^3 = \frac{\partial}{\partial z} \quad (16)$$

$$x^4 = y \frac{\partial}{\partial z} - z \frac{\partial}{\partial y} \quad (17)$$

$$x^5 = z \frac{\partial}{\partial x} - x \frac{\partial}{\partial z} \quad (18)$$

$$x^6 = x \frac{\partial}{\partial y} - y \frac{\partial}{\partial x}. \quad (19)$$

In MINKOWSKI SPACE, there are 10 Killing vectors

$$X_i^\mu = a_i^\mu \quad \text{for } i = 1, 2, 3, 4 \quad (20)$$

$$X_k^0 = 0 \quad (21)$$

$$X_k^l = \epsilon^{lkm} x_m \quad \text{for } k = 1, 2, 3 \quad (22)$$

$$X_\mu^k = \delta_\mu^{[0 \dots k]} \quad \text{for } k = 1, 2, 3. \quad (23)$$

The first group is TRANSLATION, the second ROTATION, and the final corresponds to a "boost."

## Kimberling Sequence

A sequence generated by beginning with the POSITIVE integers, then iteratively applying the following algorithm:

1. In iteration  $i$ , discard the  $i$ th element,
2. Alternately write the  $i+k$  and  $i-k$ th elements until  $k=i$ ,
3. Write the remaining elements in order.

The first few iterations are therefore

1	2	3	4	5	6	7	8	9	10	11
2	3	4	5	6	7	8	9	10	11	12
4	2	5	6	7	8	9	10	11	12	13
6	2	7	4	8	9	10	11	12	13	14
8	7	9	2	10	6	11	12	13	14	15

The diagonal elements form the sequence 1, 3, 5, 4, 10, 7, 15, ... (Sloane's A007063).

## Kings Problem

Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	
Kg		Kg		Kg		Kg	

The problem of determining how many nonattacking kings can be placed on an  $n \times n$  CHESSBOARD. For  $n = 8$ , the solution is 16, as illustrated above (Madachy 1979). In general, the solutions are

$$K(n) = \begin{cases} \frac{1}{4}n^2 & n \text{ even} \\ \frac{1}{4}(n+1)^2 & n \text{ odd} \end{cases} \quad (1)$$

(Madachy 1979), giving the sequence of doubled squares 1, 1, 4, 4, 9, 9, 16, 16, ... (Sloane's A008794). This sequence has GENERATING FUNCTION

$$\frac{1+x^2}{(1-x^2)^2(1-x)} = 1 + x + 4x^2 + 4x^3 + 9x^4 + 9x^5 + \dots \quad (2)$$

Kg		Kg		Kg			
Kg		Kg		Kg			
Kg		Kg		Kg			

The minimum number of kings needed to attack or occupy all squares on an  $8 \times 8$  CHESSBOARD is nine, illustrated above (Madachy 1979).

### Kirkman's Schoolgirl Problem

In a boarding school there are fifteen schoolgirls who always take their daily walks in rows of threes. How can it be arranged so that each schoolgirl walks in the same row with every other schoolgirl exactly once a week? Solution of this problem is equivalent to constructing a KIRKMAN TRIPLE SYSTEM of order  $n = 2$ . The following table gives one of the 7 distinct (up to permutations of letters) solutions to the problem.

Sun	Mon	Tue	Wed	Thu	Fri	Sat
ABC	ADE	AFG	AHI	AJK	ALM	ANO
DHL	BIK	BHJ	BEG	CDF	BEF	BDG
EJN	CMO	CLN	BMN	CLO	CIJ	CHK
FIO	FHN	DIM	DJO	EHM	DKN	EIL
GKM	GJL	EKO	FKL	GIN	GHO	FJM

(The table of Dörrie 1965 contains a misprint in which the  $a_1 = B$  and  $a_2 = C$  entries for Wednesday and Thursday are written simply as  $a$ .)

### Kirkman Triple System

A Kirkman triple system of order  $v = 6n + 3$  is a STEINER TRIPLE SYSTEM with parallelism (Ball and Coxeter 1987), i.e., one with the following additional stipulation: the set of  $b = (2n + 1)(3n + 1)$  triples is partitioned into  $3n + 1$  components such that each component is a  $(2n + 1)$ -subset of triples and each of the  $v$  elements appears exactly once in each component. The

STEINER TRIPLE SYSTEMS of order 3 and 9 are Kirkman triple systems with  $n = 0$  and 1. Solution to KIRKMAN'S SCHOOLGIRL PROBLEM requires construction of a Kirkman triple system of order  $n = 2$ .

Ray-Chaudhuri and Wilson (1971) showed that there exists at least one Kirkman triple system for every NON-NEGATIVE order  $n$ . Earlier editions of Ball and Coxeter (1987) gave constructions of Kirkman triple systems with  $9 \leq v \leq 99$ . For  $n = 1$ , there is a single unique (up to an isomorphism) solution, while there are 7 different systems for  $n = 2$  (Mulder 1917, Cole 1922, Ball and Coxeter 1987).

#### Kiss Surface

The QUINTIC SURFACE given by the equation

$$\frac{1}{2}x^5 + \frac{1}{2}x^4 - (y^2 + z^2) = 0.$$

#### References

- Nordstrand, T. "Surfaces." <http://www.uib.no/people/nfytn/surfaces.htm>.

#### Kissing Circles Problem

see DESCARTES CIRCLE THEOREM, SODDY CIRCLES

#### Kissing Number

The number of equivalent HYPERSPHERES in  $n$ -D which can touch an equivalent HYPERSPHERE without any intersections, also sometimes called the NEWTON NUMBER, CONTACT NUMBER, COORDINATION NUMBER, or LIGANCY. Newton correctly believed that the kissing number in 3-D was 12, but the first proofs were not produced until the 19th century (Conway and Sloane 1993, p. 21) by Bender (1874), Hoppe (1874), and Günther (1875). More concise proofs were published by Schütte and van der Waerden (1953) and Leech (1956). Exact values for *lattice packings* are known for  $n = 1$  to 9 and  $n = 24$  (Conway and Sloane 1992, Sloane and Nebe). Odlyzko and Sloane (1979) found the exact value for 24-D.

The following table gives the largest known kissing numbers in DIMENSION  $D$  for lattice ( $L$ ) and nonlattice ( $NL$ ) packings (if a nonlattice packing with higher number exists). In nonlattice packings, the kissing number may vary from sphere to sphere, so the largest value is given below (Conway and Sloane 1993, p. 15). A more extensive and up-to-date tabulation is maintained by Sloane and Nebe.

$D$	$L$	$NL$	$D$	$L$	$NL$
1	2		13	$\geq 918$	$\geq 1,130$
2	6		14	$\geq 1,422$	$\geq 1,582$
3	12		15	$\geq 2,340$	
4	24		16	$\geq 4,320$	
5	40		17	$\geq 5,346$	
6	72		18	$\geq 7,398$	
7	126		19	$\geq 10,668$	
8	240		20	$\geq 17,400$	
9	$272 \geq 306$		21	$\geq 27,720$	
10	$\geq 336 \geq 500$		22	$\geq 49,896$	
11	$\geq 438 \geq 582$		23	$\geq 93,150$	
12	$\geq 756 \geq 840$		24	196,560	

The lattices having maximal packing numbers in 12- and 24-D have special names: the COXETER-TODD LATTICE and LEECH LATTICE, respectively. The general form of the lower bound of  $n$ -D lattice densities given by

$$\eta \geq \frac{\zeta(n)}{2^{n-1}},$$

where  $\zeta(n)$  is the RIEMANN ZETA FUNCTION, is known as the MINKOWSKI-HLAWKA THEOREM.

## Klein's Absolute Invariant

$$J(q) \equiv \frac{4}{27} \frac{[1 - \lambda(q) + \lambda^2(q)]^3}{\lambda^2(q)[1 - \lambda(q)]^2} = \frac{[E_4(q)]^3}{[E_4(q)]^3 - [E_6(q)]^2}$$

(Cohn 1994), where  $q \equiv e^{\pi\tau}$  is the NOME,  $\lambda(q)$  is the ELLIPTIC LAMBDA FUNCTION

$$\lambda(q) \equiv k^2(q) = \left[ \frac{\vartheta_2(q)}{\vartheta_3(q)} \right]^4,$$

$\vartheta_i(q)$  is a THETA FUNCTION, and the  $E_i(q)$  are RAMANUJAN-EISENSTEIN SERIES.  $J(t)$  is GAMMA-MODULAR.

see also ELLIPTIC LAMBDA FUNCTION,  $j$ -FUNCTION, PI, RAMANUJAN-EISENSTEIN SERIES, THETA FUNCTION

## Klein-Beltrami Model

The Klein-Beltrami model of HYPERBOLIC GEOMETRY consists of an OPEN DISK in the Euclidean plane whose open chords correspond to hyperbolic lines. Two lines  $l$  and  $m$  are then considered parallel if their chords fail to intersect and are PERPENDICULAR under the following conditions,

1. If at least one of  $l$  and  $m$  is a diameter of the DISK, they are hyperbolically perpendicular IFF they are perpendicular in the Euclidean sense.
2. If neither is a diameter,  $l$  is perpendicular to  $m$  IFF the Euclidean line extending  $l$  passes through the pole of  $m$  (defined as the point of intersection of the tangents to the disk at the "endpoints" of  $m$ ).

There is an isomorphism between the POINCARÉ HYPERBOLIC DISK model and the Klein-Beltrami model. Consider a Klein disk in Euclidean 3-space with a SPHERE of the same radius seated atop it, tangent at the ORIGIN. If we now project chords on the disk orthogonally upward onto the SPHERE's lower HEMISPHERE, they become arcs of CIRCLES orthogonal to the equator. If we then stereographically project the SPHERE's lower HEMISPHERE back onto the plane of the Klein disk from the north pole, the equator will map onto a disk somewhat larger than the Klein disk, and the chords of the original Klein disk will now be arcs of CIRCLES orthogonal to this larger disk. That is, they will be Poincaré lines. Now we can say that two Klein lines or angles are congruent iff their corresponding Poincaré lines and angles under this isomorphism are congruent in the sense of the Poincaré model.

see also HYPERBOLIC GEOMETRY, POINCARÉ HYPERBOLIC DISK

## Klein Bottle

A closed NONORIENTABLE SURFACE of GENUS one having no inside or outside. It can be physically realized only in 4-D (since it must pass through itself without the presence of a HOLE). Its TOPOLOGY is equivalent to a pair of CROSS-CAPS with coinciding boundaries. It can be cut in half along its length to make two MÖBIUS STRIPS.

The above picture is an IMMERSION of the Klein bottle in  $\mathbb{R}^3$  (3-space). There is also another possible IMMERSION called the "figure-8" IMMERSION (Geometry Center).

The equation for the usual IMMERSION is given by the implicit equation

$$(x^2 + y^2 + z^2 + 2y - 1)[(x^2 + y^2 + z^2 - 2y - 1)^2 - 8z^2] + 16xz(x^2 + y^2 + z^2 - 2y - 1) = 0 \quad (1)$$

(Stewart 1991). Nordstrand gives the parametric form

$$x = \cos u [\cos(\frac{1}{2}u)(\sqrt{2} + \cos v) + \sin(\frac{1}{2}u) \sin v \cos v] \quad (2)$$

$$y = \sin u [\cos(\frac{1}{2}u)(\sqrt{2} + \cos v) + \sin(\frac{1}{2}u) \sin v \cos v] \quad (3)$$

$$z = -\sin(\frac{1}{2}u)(\sqrt{2} + \cos v) + \cos(\frac{1}{2}u) \sin v \cos v. \quad (4)$$

The "figure-8" form of the Klein bottle is obtained by rotating a figure eight about an axis while placing a twist in it, and is given by parametric equations

$$x(u, v) = [a + \cos(\frac{1}{2}u) \sin(v) - \sin(\frac{1}{2}u) \sin(2v)] \cos(u) \quad (5)$$

$$y(u, v) = [a + \cos(\frac{1}{2}u) \sin(v) - \sin(\frac{1}{2}u) \sin(2v)] \sin(u) \quad (6)$$

$$z(u, v) = \sin(\frac{1}{2}u) \sin(v) + \cos(\frac{1}{2}u) \sin(2v) \quad (7)$$

for  $u \in [0, 2\pi)$ ,  $v \in [0, 2\pi)$ , and  $a > 2$  (Gray 1993).

The image of the CROSS-CAP map of a TORUS centered at the ORIGIN is a Klein bottle (Gray 1993, p. 249).

Any set of regions on the Klein bottle can be colored using ss colors only (Franklin 1934, Saaty 1986).

## Klein's Equation

If a REAL curve has no singularities except nodes and CUSPS, BITANGENTS, and INFLECTION POINTS, then

$$n + 2\tau'_2 + \iota' = m + 2\delta'_2 + \kappa',$$

where  $n$  is the order,  $\tau'$  is the number of conjugate tangents,  $\iota'$  is the number of REAL inflections,  $m$  is the class,  $\delta'$  is the number of REAL conjugate points, and  $\kappa'$  is the number of REAL CUSPS. This is also called KLEIN'S THEOREM.

**Kloosterman's Sum**

$$S(u, v, n) \equiv \sum_n \exp \left[ \frac{2\pi i(uh + v\bar{h})}{n} \right], \quad (1)$$

where  $h$  runs through a complete set of residues RELATIVELY PRIME to  $n$ , and  $\bar{h}$  is defined by

$$h\bar{h} \equiv 1 \pmod{n}. \quad (2)$$

If  $(n, n') = 1$  (if  $n$  and  $n'$  are RELATIVELY PRIME), then

$$S(u, v, n)S(u, v', n') = S(u, vn'^2 + v'n^2, nn'). \quad (3)$$

Kloosterman's sum essentially solves the problem introduced by Ramanujan of representing sufficiently large numbers by QUADRATIC FORMS  $ax_1^2 + bx_2^2 + cx_3^2 + dx_4^2$ . Weil improved on Kloosterman's estimate for Ramanujan's problem with the best possible estimate

$$|S(u, v, n)| \leq 2\sqrt{n} \quad (4)$$

(Duke 1997).

**Knapsack Problem**

Given a SUM and a set of WEIGHTS, find the WEIGHTS which were used to generate the SUM. The values of the weights are then encrypted in the sum. The system relies on the existence of a class of knapsack problems which can be solved trivially (those in which the weights are separated such that they can be "peeled off" one at a time using a GREEDY-like algorithm), and transformations which convert the trivial problem to a difficult one and vice versa. Modular multiplication is used as the TRAPDOOR FUNCTION. The simple knapsack system was broken by Shamir in 1982, the Graham-Shamir system by Adleman, and the iterated knapsack by Ernie Brickell in 1984.

The problem of determining how many nonattacking knights  $K(n)$  can be placed on an  $n \times n$  CHESSBOARD. For  $n = 8$ , the solution is 32 (illustrated above). In general, the solutions are

$$K(n) = \begin{cases} \frac{1}{2}n^2 & n > 2 \text{ even} \\ \frac{1}{2}(n^2 + 1) & n > 1 \text{ odd,} \end{cases}$$

giving the sequence 1, 4, 5, 8, 13, 18, 25, ... (Sloane's A030978, Dudeney 1970, p. 96; Madachy 1979).

The minimal number of knights needed to occupy or attack every square on an  $n \times n$  CHESSBOARD is given by 1, 4, 4, 4, 5, 8, 10, ... (Sloane's A006075). The number of such solutions are given by 1, 1, 2, 3, 8, 22, 3, ... (Sloane's A006076).

### Knights of the Round Table

see NECKLACE

### Knight's Tour

A knight's tour of a CHESSBOARD (or any other grid) is a sequence of moves by a knight CHESS piece (which may only make moves which simultaneously shift one square along one axis and two along the other) such that each square of the board is visited exactly once (i.e., a HAMILTONIAN CIRCUIT). If the final position is a knight's move away from the first position, the tour is called re-entrant. The first figure above shows a knight's tour on a  $6 \times 6$  CHESSBOARD. The second set of figures shows six knight's tours on an  $8 \times 8$  CHESSBOARD, all but the first of which are re-entrant. The final tour has the additional property that it is a SEMIMAGIC SQUARE with row and column sums of 260 and main diagonal sums of 348 and 168.

Löbbing and Wegener (1996) computed the number of cycles covering the directed knight's graph for an  $8 \times 8$  CHESSBOARD. They obtained  $\alpha^2$ , where  $\alpha = 2,849,759,680$ , i.e., 8,121,130,233,753,702,400. They also computed the number of undirected tours, obtaining an incorrect answer 33,439,123,484,294 (which is not divisible by 4 as it must be), and so are currently redoing the calculation.

The following results are given by Kraitichik (1942). The number of possible tours on a  $4k \times 4k$  board for  $k = 3, 4, \dots$  are 8, 0, 82, 744, 6378, 31088, 189688, 1213112, ... (Kraitichik 1942, p. 263). There are 14 tours on the  $3 \times 7$  rectangle, two of which are symmetrical. There are 376 tours on the  $3 \times 8$  rectangle, none of which is closed. There are 16 symmetric tours on the  $3 \times 9$  rectangle and 8 closed tours on the  $3 \times 10$  rectangle. There are 58 symmetric tours on the  $3 \times 11$  rectangle and 28 closed tours on the  $3 \times 12$  rectangle. There are five doubly symmetric tours on the  $6 \times 6$  square. There are 1728 tours on the  $5 \times 5$  square, 8 of which are symmetric. The longest "uncrossed" knight's tours on an  $n \times n$  board for  $n = 3, 4, \dots$  are 2, 5, 10, 17, 24, 35, ... (Sloane's A003192).

## Knödel Numbers

For every  $k \geq 1$ , let  $C_k$  be the set of COMPOSITE numbers  $n > k$  such that if  $1 < a < n$ ,  $\text{GCD}(a, n) = 1$  (where GCD is the GREATEST COMMON DIVISOR), then  $a^{n-k} \equiv 1 \pmod{n}$ .  $C_1$  is the set of CARMICHAEL NUMBERS. Makowski (1962/1963) proved that there are infinitely many members of  $C_k$  for  $k \geq 2$ .

## Knot

A knot is defined as a closed, non-self-intersecting curve embedded in 3-D. A knot is a single component LINK. Klein proved that knots cannot exist in an EVEN-numbered dimensional space  $\geq 4$ . It has since been shown that a knot cannot exist in *any* dimension  $\geq 4$ . Two distinct knots cannot have the same KNOT COMPLEMENT (Gordon and Luecke 1989), but two LINKS can! (Adams 1994, p. 261). The KNOT SUM of any number of knots cannot be the UNKNOT unless each knot in the sum is the UNKNOT.

Knots can be cataloged based on the minimum number of crossings present. Knots are usually further broken down into PRIME KNOTS. Knot theory was given its first impetus when Lord Kelvin proposed a theory that atoms were vortex loops, with different chemical

elements consisting of different knotted configurations (Thompson 1867). P. G. Tait then cataloged possible knots by trial and error.

Thistlethwaite has used DOWKER NOTATION to enumerate the number of PRIME KNOTS of up to 13 crossings, and ALTERNATING KNOTS up to 14 crossings. In this compilation, MIRROR IMAGES are counted as a single knot type. The number of distinct PRIME KNOTS  $N(n)$  for knots from  $n = 3$  to 13 crossings are 1, 1, 2, 3, 7, 21, 49, 165, 552, 2176, 9988 (Sloane's A002863). Combining PRIME KNOTS gives one additional type of knot each for knots six and seven crossings.

Let  $C(n)$  be the number of distinct PRIME KNOTS of  $n$  crossings, counting CHIRAL versions of the same knot separately. Then

$$\frac{1}{3}(2^{n-2} - 1) \leq N(n) \lesssim e^n$$

(Ernst and Summers 1987). Welsh has shown that the number of knots is bounded by an exponential in  $n$ .

A pictorial enumeration of PRIME KNOTS of up to 10 crossings appears in Rolfsen (1976, Appendix C). Note, however, that in this table, the PERKO PAIR 10<sub>161</sub> and 10<sub>162</sub> are actually identical, and the uppermost crossing in 10<sub>144</sub> should be changed (Jones 1987). The  $k$ th knot having  $n$  crossings in this (arbitrary) ordering of knots is given the symbol  $n_k$ . Another possible representation for knots uses the BRAID GROUP. A knot with  $n + 1$  crossings is a member of the BRAID GROUP  $n$ . There is no general method known for deciding whether two given knots are equivalent or interlocked. There is no general ALGORITHM to determine if a tangled curve is a knot. Haken (1961) has given an ALGORITHM, but it is too complex to apply to even simple cases.

If a knot is AMPHICHIRAL, the "amphichirality" is  $A = 1$ , otherwise  $A = 0$  (Jones 1987). ARF INVARIANTS are designated  $a$ . BRAID WORDS are denoted  $b$  (Jones 1987). CONWAY'S KNOT NOTATION  $C$  for knots up to 10 crossings is given by Rolfsen (1976). Hyperbolic volumes are given (Adams, Hildebrand, and Weeks 1991; Adams 1994). The BRAID INDEX  $i$  is given by Jones (1987). ALEXANDER POLYNOMIALS  $\Delta$  are given in Rolfsen (1976), but with the POLYNOMIALS for 10<sub>083</sub> and 10<sub>086</sub> reversed (Jones 1987). The ALEXANDER POLYNOMIALS are normalized according to Conway, and given in abbreviated form  $[a_1, a_2, \dots \text{ for } a_1 + a_2(x^{-1} + x) + \dots$

The JONES POLYNOMIALS  $W$  for knots of up to 10 crossings are given by Jones (1987), and the JONES POLYNOMIALS  $V$  can be either computed from these, or taken from Adams (1994) for knots of up to 9 crossings (although most POLYNOMIALS are associated with the wrong knot in the first printing). The JONES POLYNOMIALS are listed in the abbreviated form  $\{n\} a_0 a_1 \dots$  for  $t^{-n}(a_0 + a_1 t + \dots)$ , and correspond either to the knot depicted by Rolfsen or its MIRROR IMAGE, whichever

has the lower POWER of  $t^{-1}$ . The HOMFLY POLYNOMIAL  $P(\ell, m)$  and KAUFFMAN POLYNOMIAL  $F(a, x)$  are given in Lickorish and Millett (1988) for knots of up to 7 crossings.

M. B. Thistlethwaite has tabulated the HOMFLY POLYNOMIAL and KAUFFMAN POLYNOMIAL  $F$  for KNOTS of up to 13 crossings.

3<sub>1</sub>4<sub>1</sub>5<sub>1</sub>5<sub>2</sub>6<sub>1</sub>6<sub>2</sub>6<sub>3</sub>7<sub>1</sub>7<sub>2</sub>7<sub>3</sub>7<sub>4</sub>7<sub>5</sub>7<sub>6</sub>7<sub>7</sub>8<sub>1</sub>8<sub>2</sub>8<sub>3</sub>8<sub>4</sub>8<sub>5</sub>8<sub>6</sub>8<sub>7</sub>8<sub>8</sub>8<sub>9</sub>8<sub>10</sub>8<sub>11</sub>8<sub>12</sub>8<sub>13</sub>8<sub>14</sub>8<sub>15</sub>8<sub>16</sub>8<sub>17</sub>8<sub>18</sub>8<sub>19</sub>8<sub>20</sub>8<sub>21</sub>9<sub>1</sub>9<sub>2</sub>9<sub>3</sub>9<sub>4</sub>9<sub>5</sub>9<sub>6</sub>9<sub>7</sub>9<sub>8</sub>9<sub>9</sub>9<sub>10</sub>9<sub>11</sub>9<sub>12</sub>9<sub>13</sub>9<sub>14</sub>9<sub>15</sub>9<sub>16</sub>9<sub>17</sub>9<sub>18</sub>9<sub>19</sub>9<sub>20</sub>9<sub>21</sub>9<sub>22</sub>9<sub>23</sub>9<sub>24</sub>9<sub>25</sub>9<sub>26</sub>9<sub>27</sub>9<sub>28</sub>9<sub>29</sub>9<sub>30</sub>9<sub>31</sub>9<sub>32</sub>9<sub>33</sub>9<sub>34</sub>9<sub>35</sub>9<sub>36</sub>9<sub>37</sub>9<sub>38</sub>9<sub>39</sub>9<sub>40</sub>

**Knot Determinant**

The determinant of a knot is  $|\Delta(-1)|$ , where  $\Delta(z)$  is the ALEXANDER POLYNOMIAL.

**Knot Diagram**

A picture of a projection of a KNOT onto a PLANE. Usually, only double points are allowed (no more than two points are allowed to be superposed), and the double or crossing points must be “genuine crossings” which transverse in the plane. This means that double points must look like the below diagram on the left, and not the one on the right.

Also, it is usually demanded that a knot diagram contain the information if the crossings are overcrossings or undercrossings so that the original knot can be reconstructed. Here is a knot diagram of the TREFOIL KNOT,

KNOT POLYNOMIALS can be computed from knot diagrams. Such POLYNOMIALS often (but not always) allow the knots corresponding to given diagrams to be uniquely identified.

## Knot Exterior

The COMPLEMENT of an open solid TORUS knotted at the KNOT. The removed open solid TORUS is called a tubular NEIGHBORHOOD.

## Knot Linking

In general, it is possible to link two  $n$ -D HYPERSPHERES in  $(n+2)$ -D space in an infinite number of inequivalent ways. In dimensions greater than  $n+2$  in the piecewise linear category, it is true that these spheres are themselves unknotted. However, they may still form nontrivial links. In this way, they are something like higher dimensional analogs of two 1-spheres in 3-D. The following table gives the number of nontrivial ways that two  $n$ -D HYPERSPHERES can be linked in  $k$ -D.

D of spheres	D of space	Distinct Linkings
23	40	239
31	48	959
102	181	3
102	182	10438319
102	183	3

Two 10-D HYPERSPHERES link up in 12, 13, 14, 15, and 16-D, then unlink in 17-D, link up again in 18, 19, 20, and 21-D. The proof of these results consists of an "easy part" (Zeeman 1962) and a "hard part" (Ravenel 1986). The hard part is related to the calculation of the (stable and unstable) HOMOTOPY GROUPS of SPHERES.

## Knot Polynomial

A knot invariant in the form of a POLYNOMIAL such as the ALEXANDER POLYNOMIAL, BLM/HO POLYNOMIAL, BRACKET POLYNOMIAL, CONWAY POLYNOMIAL, JONES POLYNOMIAL, KAUFFMAN POLYNOMIAL  $F$ , KAUFFMAN POLYNOMIAL  $X$ , and VASSILIEV POLYNOMIAL.

## References

- Lickorish, W. B. R. and Millett, K. C. "The New Polynomial Invariants of Knots and Links." *Math. Mag.* 61, 3-23, 1988.

## Knot Problem

The problem of deciding if two KNOTS in 3-space are equivalent such that one can be continuously deformed into another.

## Knot Shadow

A LINK DIAGRAM which does not specify whether crossings are under- or overcrossings.

## Knot Sum

Two oriented knots (or links) can be summed by placing them side by side and joining them by straight bars so that orientation is preserved in the sum. This operation is denoted  $\#$ , so the knot sum of knots  $K_1$  and  $K_2$  is written

$$K_1 \# K_2 = K_2 \# K_1.$$

see also CONNECTED SUM

## Knot Theory

The mathematical study of KNOTS. Knot theory considers questions such as the following:

1. Given a tangled loop of string, is it really knotted or can it, with enough ingenuity and/or luck, be untangled without having to cut it?
2. More generally, given two tangled loops of string, when are they deformable into each other?
3. Is there an effective algorithm (or any algorithm to speak of) to make these determinations?

Although there has been almost explosive growth in the number of important results proved since the discovery of the JONES POLYNOMIAL, there are still many "knotty" problems and conjectures whose answers remain unknown.

## Knot Vector

see B-SPLINE

## Koch Antisnowflake

A FRACTAL derived from the KOCH SNOWFLAKE. The base curve and motif for the fractal are illustrated below.

The AREA after the  $n$ th iteration is

$$A_n = A_{n-1} - \frac{1}{3} \frac{\ell_{n-1}}{a} \frac{\Delta}{3^n},$$

where  $\Delta$  is the area of the original EQUILATERAL TRIANGLE, so from the derivation for the KOCH SNOWFLAKE,

$$A \equiv \lim_{n \rightarrow \infty} A_n = (1 - \frac{3}{5})\Delta = \frac{2}{5}\Delta.$$

**Koch Island**

see KOCH SNOWFLAKE

**Koch Snowflake**

A FRACTAL, also known as the KOCH ISLAND, which was first described by Helge von Koch in 1904. It is built by starting with an EQUILATERAL TRIANGLE, removing the inner third of each side, building another EQUILATERAL TRIANGLE at the location where the side was removed, and then repeating the process indefinitely. The Koch snowflake can be simply encoded as a LINDENMAYER SYSTEM with initial string "F--F--F", STRING REWRITING rule "F" → "F+F--F+F", and angle 60°. The zeroth through third iterations of the construction are shown above. The fractal can also be constructed using a base curve and motif, illustrated below.

Let  $N_n$  be the number of sides,  $L_n$  be the length of a single side,  $\ell_n$  be the length of the PERIMETER, and  $A_n$  the snowflake's AREA after the  $n$ th iteration. Further, denote the AREA of the initial  $n = 0$  TRIANGLE  $\Delta$ , and the length of an initial  $n = 0$  side 1. Then

$$N_n = 3 \cdot 4^n \quad (1)$$

$$L_n = \left(\frac{1}{3}\right)^n = 3^{-n} \quad (2)$$

$$\ell_n \equiv N_n L_n = 3\left(\frac{4}{3}\right)^n \quad (3)$$

$$\begin{aligned} A_n &= A_{n-1} + \frac{1}{4} N_n L_n^2 \Delta = A_{n-1} + \frac{3 \cdot 4^n}{4} \left(\frac{1}{3}\right)^{2n} \Delta \\ &= A_{n-1} + \frac{3 \cdot 4^{n-1}}{9^n} \Delta = A_{n-1} + \frac{3 \cdot 4^{4-1}}{9 \cdot 9^{n-1}} \Delta \\ &= A_{n-1} + \frac{1}{3} \left(\frac{4}{9}\right)^{n-1} \Delta. \end{aligned} \quad (4)$$

The CAPACITY DIMENSION is then

$$\begin{aligned} d_{\text{cap}} &= - \lim_{n \rightarrow \infty} \frac{\ln N_n}{\ln L_n} = - \lim_{n \rightarrow \infty} \frac{\ln(3 \cdot 4^n)}{\ln(3^{-n})} \\ &= \lim_{n \rightarrow \infty} \frac{\ln 3 + n \ln 4}{n \ln 3} \\ &= \frac{\ln 4}{\ln 3} = \frac{2 \ln 2}{\ln 3} = 1.261859507 \dots \end{aligned} \quad (5)$$

Now compute the AREA explicitly,

$$A_0 = \Delta \quad (6)$$

$$A_1 = A_0 + \frac{1}{3} \left(\frac{4}{9}\right)^0 \Delta = \Delta \left\{ 1 + \frac{1}{3} \left(\frac{4}{9}\right)^0 \right\} \quad (7)$$

$$A_2 = A_1 + \frac{1}{3} \left(\frac{4}{9}\right)^1 \Delta = \Delta \left\{ 1 + \frac{1}{3} \left[ \left(\frac{4}{9}\right)^0 + \left(\frac{4}{9}\right)^1 \right] \right\} \quad (8)$$

$$A_n = \left[ 1 + \frac{1}{3} \sum_{k=0}^n \left(\frac{4}{9}\right)^k \right] \Delta, \quad (9)$$

so as  $n \rightarrow \infty$ ,

$$\begin{aligned} A &\equiv A_\infty = \left[ 1 + \frac{1}{3} \sum_{k=1}^{\infty} \left(\frac{4}{9}\right)^k \right] \Delta = \left( 1 + \frac{1}{3} \frac{1}{1 - \frac{4}{9}} \right) \Delta \\ &= \frac{8}{5} \Delta. \end{aligned} \quad (10)$$

Some beautiful TILINGS, a few examples of which are illustrated above, can be made with iterations toward Koch snowflakes.

In addition, two sizes of Koch snowflakes in AREA ratio 1:3 TILE the PLANE, as shown above (Gosper).

Another beautiful modification of the Koch snowflake involves inscribing the constituent triangles with filled-in triangles, possibly rotated at some angle. Some sample results are illustrated above for 3 and 4 iterations.

### Kolmogorov-Arnold-Moser Theorem

A theorem outlined in 1954 by Kolmogorov which was subsequently proved in the 1960s by Arnold and Moser (Tabor 1989, p. 105). It gives conditions under which CHAOS is restricted in extent. Moser's 1962 proof was valid for TWIST MAPS

$$\theta' = \theta + 2\pi f(I) + g(\theta, I) \quad (1)$$

$$I' = I + f(\theta, I). \quad (2)$$

In 1963, Arnold produced a proof for Hamiltonian systems

$$H = H_0(I) + \epsilon H_1(I). \quad (3)$$

The original theorem required perturbations  $\epsilon \sim 10^{-48}$ , although this has since been significantly increased. Arnold's proof required  $C^\infty$ , and Moser's original proof

required  $C^{333}$ . Subsequently, Moser's version has been reduced to  $C^6$ , then  $C^{2+\epsilon}$ , although counterexamples are known for  $C^2$ . Conditions for applicability of the KAM theorem are:

1. small perturbations,
2. smooth perturbations, and
3. sufficiently irrational WINDING NUMBER.

Moser considered an integrable Hamiltonian function  $H_0$  with a TORUS  $T_0$  and set of frequencies  $\omega$  having an incommensurate frequency vector  $\omega^*$  (i.e.,  $\omega \cdot \mathbf{k} \neq 0$  for all INTEGERS  $k_i$ ). Let  $H_0$  be perturbed by some periodic function  $H_1$ . The KAM theorem states that, if  $H_1$  is small enough, then for almost every  $\omega^*$  there exists an invariant TORUS  $T(\omega^*)$  of the perturbed system such that  $T(\omega^*)$  is "close to"  $T_0(\omega^*)$ . Moreover, the TORI  $T(\omega^*)$  form a set of POSITIVE measures whose complement has a measure which tends to zero as  $|H_1| \rightarrow 0$ . A useful paraphrase of the KAM theorem is, "For sufficiently small perturbation, almost all TORI (excluding those with rational frequency vectors) are preserved." The theorem thus explicitly excludes TORI with rationally related frequencies, that is,  $n-1$  conditions of the form

$$\omega \cdot \mathbf{k} = 0. \quad (4)$$

These TORI are destroyed by the perturbation. For a system with two DEGREES OF FREEDOM, the condition of closed orbits is

$$\sigma = \frac{\omega_1}{\omega_2} = \frac{r}{s}. \quad (5)$$

For a QUASIPERIODIC ORBIT,  $\sigma$  is IRRATIONAL. KAM shows that the preserved TORI satisfy the irrationality condition

$$\left| \frac{\omega_1}{\omega_2} - \frac{r}{s} \right| > \frac{K(\epsilon)}{s^{2.5}} \quad (6)$$

for all  $r$  and  $s$ , although not much is known about  $K(\epsilon)$ .

The KAM theorem broke the deadlock of the small divisor problem in classical perturbation theory, and provides the starting point for an understanding of the appearance of CHAOS. For a HAMILTONIAN SYSTEM, the ISOENERGETIC NONDEGENERACY condition

$$\left| \frac{\partial^2 H_0}{\partial I_j \partial I_j} \right| \neq 0 \quad (7)$$

guarantees preservation of most invariant TORI under small perturbations  $\epsilon \ll 1$ . The Arnold version states that

$$\left| \sum_{k=1}^n m_k \omega_k \right| > K(\epsilon) \left( \sum_{k=1}^n |m_k| \right)^{-n-1} \quad (8)$$

for all  $m_k \in \mathbb{Z}$ . This condition is less restrictive than Moser's, so fewer points are excluded.

### Kolmogorov Entropy

Also known as METRIC ENTROPY. Divide PHASE SPACE into  $D$ -dimensional HYPERCUBES of CONTENT  $\epsilon^D$ . Let  $P_{i_0, \dots, i_n}$  be the probability that a trajectory is in HYPERCUBE  $i_0$  at  $t = 0$ ,  $i_1$  at  $t = T$ ,  $i_2$  at  $t = 2T$ , etc. Then define

$$K_n = h_K = - \sum_{i_0, \dots, i_n} P_{i_0, \dots, i_n} \ln P_{i_0, \dots, i_n}, \quad (1)$$

where  $K_{N+1} - K_N$  is the information needed to predict which HYPERCUBE the trajectory will be in at  $(n+1)T$  given trajectories up to  $nT$ . The Kolmogorov entropy is then defined by

$$K \equiv \lim_{T \rightarrow 0} \lim_{\epsilon \rightarrow 0^+} \lim_{N \rightarrow \infty} \frac{1}{NT} \sum_{n=0}^{N-1} (K_{n+1} - K_n). \quad (2)$$

The Kolmogorov entropy is related to LYAPUNOV CHARACTERISTIC EXPONENTS by

$$h_K = \int_P \sum_{\sigma_i > 0} \sigma_i d\mu. \quad (3)$$

### Kolmogorov-Sinai Entropy

see KOLMOGOROV ENTROPY, METRIC ENTROPY

**Kolmogorov-Smirnov Test**

A goodness-of-fit test for any DISTRIBUTION. The test relies on the fact that the value of the sample cumulative density function is asymptotically normally distributed.

To apply the Kolmogorov-Smirnov test, calculate the cumulative frequency (normalized by the sample size) of the observations as a function of class. Then calculate the cumulative frequency for a true distribution (most commonly, the NORMAL DISTRIBUTION). Find the greatest discrepancy between the observed and expected cumulative frequencies, which is called the "*D*-STATISTIC." Compare this against the critical *D*-STATISTIC for that sample size. If the calculated *D*-STATISTIC is greater than the critical one, then reject the NULL HYPOTHESIS that the distribution is of the expected form. The test is an *R*-ESTIMATE.

see also ANDERSON-DARLING STATISTIC, *D*-STATISTIC, KUIPER STATISTIC, NORMAL DISTRIBUTION, *R*-ESTIMATE

**Krawtchouk Polynomial**

Let  $\alpha(x)$  be a STEP FUNCTION with the JUMP

$$j(x) = \binom{N}{x} p^x q^{N-x} \quad (1)$$

at  $x = 0, 1, \dots, N$ , where  $p > 0, q > 0$ , and  $p + q = 1$ . Then

$$k_n^{(p)}(x) = \left[ \binom{N}{n} \right]^{-1/2} (pq)^{-n/2} \times \sum_{\nu=0}^n (-1)^{n-\nu} \binom{N-x}{n-\nu} \binom{x}{\nu} p^{n-\nu} q^{\nu}, \quad (2)$$

for  $n = 0, 1, \dots, N$ . It has WEIGHT FUNCTION

$$w = \frac{N! p^x q^{N-x}}{\Gamma(1+x)\Gamma(N+1-x)}, \quad (3)$$

where  $\Gamma(x)$  is the GAMMA FUNCTION, RECURRENCE RELATION

$$\begin{aligned} (n+1)k_{n+1}^{(p)}(x) + pq(N-n+1)k_{n-1}^{(p)}(x) \\ = [x-n-(N-2)]k_n^{(p)}(x), \end{aligned} \quad (4)$$

and squared norm

$$\frac{N!}{n!(N-n)!} (pq)^n. \quad (5)$$

It has the limit

$$\lim_{n \rightarrow \infty} \left( \frac{2}{Npq} \right)^{n/2} n! k_n^{(p)}(Np + \sqrt{2Npq}s) = H_n(s), \quad (6)$$

where  $H_n(x)$  is a HERMITE POLYNOMIAL, and is related to the HYPERGEOMETRIC FUNCTION by

$$\begin{aligned} k_n^{(p)}(x, N) &= k_n^{(p)}(x, N) \\ &= (-1)^n \binom{N}{n} p^n {}_2F_1(-n, -x; -N; 1/p) \\ &\quad \frac{(-1)^n p^n}{n!} \frac{\Gamma(N-x+1)}{\Gamma(N-x-n+1)} \\ &\quad \times {}_2F_1(-n, -x; N-x-n+1; -q/p). \end{aligned} \quad (7)$$

#### Kreisel Conjecture

A CONJECTURE in DECIDABILITY theory which postulates that, if there is a uniform bound to the lengths of shortest proofs of instances of  $S(n)$ , then the universal generalization is necessarily provable in PEANO ARITHMETIC. The CONJECTURE was proven true by M. Baaz in 1988 (Baaz and Pudlák 1993).
